Preface

It is our pleasure to welcome you to the 2014 4th International Conference on Materials Science and Information Technology (MSIT 2014) in Tianjin, China. MSIT 2014 is the first conference dedicated to issues related to Materials Science , Mechatronics, Manufacturing Technology, Control, Measurement and Monitoring, Information Technology， Computer Engineering and Applied Computing Methods, Energy and Environmental Engineering. A major goal and feature of it is to bring academic scientists, engineers, industrial researchers together to exchange and share their experiences and research results about most aspects of Materials Science , Mechatronics, Manufacturing Technology, Control, Measurement and Monitoring, Information Technology， Computer Engineering and Applied Computing Methods, Energy and Environmental Engineering, and discuss the practical challenges encountered and the solutions adopted.

We hope you will have a technically rewarding experience, and use this occasion to meet old friends and make many new ones. Don’t miss the opportunity to explore in Tianjin, China. And don’t forget to take a sample of the many and diverse attractions in the rest of the China.

MSIT 2014 promises to be both stimulating and informative with a wonderful array of keynote and invited speakers from all over the world. Delegates will have a wide range of sessions to choose from and will have a difficult decision in deciding which sessions to attend.

The program consists of invited sessions, and technical workshops and discussions with eminent speakers covering a wide range of topics in Materials Science , Mechatronics, Manufacturing Technology, Control, Measurement and Monitoring, Information Technology， Computer Engineering and Applied Computing Methods, Energy and Environmental Engineering. This rich program provides all attendees with the opportunities to meet and interact with one another. We hope your experience with MSIT 2014 is a fruitful and long lasting one. With your support and participation, the conference will continue its success for a long time.

We would like to thank the organization staff, the members of the program committees and reviewers. They have worked very hard in reviewing papers and making valuable suggestions for the authors to improve their work. We also would like to express our gratitude to the external reviewers, for providing extra helps in the review process, and the authors for contributing their research result to the conference. Special thanks go to TTP Publisher.

We wish all attendees of MSIT 2014 an enjoyable scientific gathering in Tianjin, China. We look forward to seeing all of you next year at the conference.

Program Committee Chair

Dr. S. Z. Cai

Table of Contents

Preface

Chapter 1: Advanced Materials Science, Chemical Engineering and Processing Technologies

High Value Added Utilization of Vanadium Slag
T. Du, X. Fang and X.P. Zhang 3

Preparation of Zeolite 4A Using Laterite Nickel Slag and the Characteristic Study of CO_2/N_2 Separation
T. Du, S.L. Li and F. Yang 7

Bi_2S_3 Nanoflowers Synthesized via Hydrothermal Method
X.L. Chen and Y.P. Ji 11

Study of Oxidation Degradation Eosin by Ferrate
D.S. Li and X.L. Chen 15

The Relationship between Calcium Hydroxide Concentration in Pore Solution and the Strength of Stabilized Soils
L. Dai and X.X. Deng 19

Development and Application of the Screw Separator
J.B. Yin, J. Lu, L. Zhao and S.S. Wang 23

On Laser Shock Processing to Improve Hot Corrosion Resistance of In718 Superalloy
Y.C. Bai, Y.Q. Hua, Z. Rong, Q. Xue and R.F. Chen 27

Extraction and Purification of Fluorene from Wash Oil
Y.S. E 31

Microwave Hydrothermal Synthesis and Characterization of In_2O_3 Nanocrystalline
Y.Y. Hu, W.X. Ye, J. Lei, Q.X. Zhu, W.Q. Xiong and X.H. Liao 35

Synthesis of High-Strength and Water-Resistant Phosphogypsum Small Hollow Block
H.B. Xie, W.B. Ma and C.T. Ye 39

Study on Laser Micro Shock Effect on Electrical Resistivity of Nanometer Copper Film
Q. Xue, Y.Q. Hua, Y.C. Bai, R.F. Chen and H.X. Liu 45

Effect of Process Parameters on Residual Stress Distribution during Direct Laser Metal Deposition Shaping
H. Wang 49

Plasma-Induced Degradation of Benzene in Aqueous Solution
H.L. Qi, K. Gai and D.P. Ma 55

Liquid Phase Rhodamine Boxidation Induced by Plasma with Glow Discharge Electrolysis
K. Gai, H.L. Qi, D.P. Ma and Y.Q. Zhang 60

The Preparation of ZnO: Al Thin Films on Flexible Substrates by Magnetron Sputtering Method
X.J. Wang 65

Analysis Analysis and Suggestions on Device Clamp Screw Fracture of 110kV Transmission Line
X.X. Xu, W.Y. Li, G.X. Zhang, Y.T. Feng, H. Ke, Q. Wang and H.X. Cui 69

Ply Thickness' Effect on Composite Laminate under Low-Velocity Impact
X.C. Luo, T. Zhang and Q.S. Wang 74

Study on the Synthesis of Ethylene Glycol by Catalytic Hydrolyze of Ethylene Carbonate
M. Zhang 79

Efficient Synthesis 2,3-Dihydroquinazolin-4(1H)-Ones Using Coconut Shell Char Sulfonic Acid as a Reusable Catalyst in Ethanol
X.Y. Liu and Z.G. Yang 83

Study on the Urea Demand Model of SCR Control Technology
Z.L. Liu and D. Wa 87

Effect of Sodium Methylacrysulfonate upon the Molecular Weight and Performance of Polycarboxylate Superplasticizer
L. Xiong, G.J. Zheng, Y. Bi, C.F. Fu and S.F. Wang 91

Influence of the pH Value on the Water-Reducing Performance of Polycarboxylate-Based Superplasticizers at Room Temperature
J.W. Wang, G.J. Zheng, S.F. Wang, C.F. Fu and Y. Bi 97

Preparation and *In Vitro* Release Behaviors of Paclitaxel-Loaded Pluronic F87/Poly(Lactic Acid) Nanoparticle
Z.L. Li, Y.S. Huang, X.Y. Xiong, Y.C. Gong and Y.P. Li 102

Application of High-Efficiency Reverse Osmosis Technology in Reclaimed Water Treatment in Power Plants
X. Long, Q. Zhu, X.Y. Wang and J.H. Shi 108

Measurement of Ultra Low Sulfur in IN718 by Using Infrared Absorption Method
P.R. Zalupski and F.Y. Liu 115

The Synthesis and Characterization of Polyphenylene Vinylene (PPV) Derivatives with Alkoxy Branched Chains
X.Z. Zhang and Y.W. Wang 121

Comparison and Characterization of Two Preparation Methods of Graphene Oxide
H.B. Liu, W.Y. Zhang, F. Lin and H.D. Cao 125

Detection of Phase Purity of Sr_2FeMoO_6 by Raman Spectroscopy
Z.F. Xu, Q. Zhang and S.J. Yuan 130

A Novel Environment Friendly Material: Sucrose Char Sulfonic Acid Catalyzed Three-Component Mannich Reaction
Y.Y. She, X.Y. Liu and Z.G. Yang 134

Investigation of Sewage Sludge Anaerobic Digestion Performance Using Peracetic Acid as a Pretreatment
N. Wei 138

Synthesis and Characterization of Sulfonated Poly(Arylene Ether Sulfone) Multiblock Copolymers for Proton Exchange Membrane
T. Xue, Z.X. Hu and S.W. Chen 142

Study on Carbon and Sulfur Detection by Using Infrared Absorption Method
M.R. Bayati and P.Y. Wei 146

Effects of the Carboxyl Density on the Properties of Polycarboxylate-Type Superplasticizer
C.F. Fu, G.J. Zheng, K.L. Li, Y. Bi and L. Xiong 151

Preparation of Copolymer Modified with Oxidized Starch and Dispersion Ability for Ferric Oxide
J.C. Xu, X.S. Rong, X.R. Guo and F.X. Qiu 156

Corrosion Inhibitor Polymer Modified with Acid Activated Attapulgite: Preparation and Performance of Dispersing Ferric Oxide
J.C. Xu, X.S. Rong, X.R. Guo and F.X. Qiu 160

Preparation of a Novel Magnetic Stir Bar for the Pretreatment of the Plasticizers in Lake Water
R. Feng 164

Simulation of CVD Diamond Film Growth by Method of Revised KMC
L.Z. Zhang and F.Z. Wang 168

Relaxation Properties of the Solid Propellant Based on Hydroxyl-Terminated Polybutadiene
Z.M. Xie, S.C. Chen and Y.S. Wang 172

Effect of Fiber's Surface Pretreatment on the Interfacial Bonding Strength between Steel Fiber and Resin
H. Yang, J.H. Zhang, G.Y. Sun and Y. Zhang 177

Synthesis Alloy and Composite Materials of Nano-Silver-Nickel
W.J. Cui, L. Wang, J.W. Fu and D.Y. Zhao 181

Synthesis and Phase Behavior of a New Thiophene Monomer as Nematic Liquid Crystal
L. Wang, Y.J. Xie, X.X. Zhang and J.S. Hu 185

Synthesis of Novel Cationic Asphalt Emulsifier and its Investigation by Online FTIR Spectrophotometry
M.J. Sun, L.S. Shi, Z.Y. Jin, N. Li and X. Tao 189

Original Silk Pre-Oxidation Treatment of Carbon Fiber from Coal Tar Pitch
X.F. Zhao, Y.F. Wen, T. Qi, S.Q. Lai and L.J. Gao 194

4
X.E. Zhao 199

New Seawater Flocculants
J.A. Hao, B. Yang, X.Q. Zhang, A.J. Zhang, T.X. Jiang, X.Z. Zhang, J. Wang and Y.S. Zhang 203

Research on the Corrosion Resistance of Tinplate with Reflowing Technology
C.Q. An, C.M. Liu, H. Wang and S.D. Zhang 208

Effect of Ferrite Volume Fraction on Mechanical Properties of X80 Pipeline Steel
J. Liu, G. Zhu and W. Mao 212

Computer Simulation: A Tool for Researching the Basic Physical Properties of NiAl and Ni_3Al
C. Xu and D. Chen 216

Newly Determined Crystal Structure and Optical Property of the Intermetallic NiAl and Ni_3Al Alloys: A First-Principles Computer Simulated Investigation
C. Xu and D. Chen 220

TiO_2-Based Composite Film for the Photodegradation of Methyl Green
N. Song, F. Li and M.M. Yao 224

Synthesis and Characterization on a Kind of Polycarboxylate Superplasticizer
X. Li, G.J. Zheng, Y. Bi, C.F. Fu, M.H. Yuan and S.F. Wang 228

Synthesis for an Amide-Ester Type Polycarboxylate Superplasticizer and its Application in Concrete
C. Sun, G.J. Zheng, Y. Bi and H. Zhou 233

High Cycle Fatigue Performances of Advanced High Strength Steel CP800
L.M. Gui, X.C. Jin, H.T. Li and M. Zhang 238

Preparation and Dielectric Property of Ag/PVDF Composite Film
Y.J. Wang, J.W. Zhai, F.F. Wang and C.G. Feng 242

Microstructure and Wear Resistance of $Cu_{0.9}$NiAlCoCrFe High Entropy Alloy Coating on AZ91D Magnesium Alloys by Laser Cladding
K.J. Huang, Y.Y. Wang and X. Lin 246

Temporal and Spatial Characterizations of Zn Ions in Plasma by Pulsed-Laser Ablation of Zinc Metal in Vacuum Condition
Y. Jiao 251

Lignite-Fired CFB Boiler SO_2, NO Emission Control Technology Research
J.M. Yang, B.Z. Wang and W. Wang 256

Laying the Ground of Indoor Restrooms by Using Foam Glass and Waterproof Coating
S.M. Shi 260

Influence of Mo Addition on a Nickel-Base Single Crystal Superalloy
K. Zhao 264

Superhydrophobicity of Silicon-Based Microstructured Surfaces
G. Li 267

Research on Erosion Resistance of TiB_2 Ceramic Particle Reinforced MMC Coating
J.J. Fang, Y.J. Song and Z.X. Li 270

The Application of New Material in Industrial Design
L.L. Wang, T.T. Xie and Y.J. Liu 276

Spherical $SrCO_3$ Nanopowder Synthesized by Super Gravity Method
Z.S. Yang, J.H. Jin, B. Li, X.W. Zou Qi and Y.Z. Gang 280

Synthesis of a Novel Donor Unit for Organic Light-Emitting Materials: 10-octyl-3,7-di(thiophen-2-Yl)-10H-Phenothiazine
Z.B. Tang, X.X. Sun, L.P. Miao and H.Y. Shen 284

Current Situation and Latest Development of Intelligent Materials
G.M. Lin, F. Yuan and Y.H. Li 288

Synthesis of a Novel D-A Type Molecule Based on Carbazole Unit for Organic Light-Emitting Material Applications
Z.B. Tang, X.X. Sun, H.W. Yan and L.P. Miao 292

Growth Behavior of WC Grains in Ni_3Al Matrix during Liquid Phase Sintering
W.B. Zhang, W. Peng, J.Z. Long and X.Y. Wei 297

Synthesis and Characterization of Nano Melamine Phosphate
Z.Z. Wang and S.H. Xu 301

Preparation and Characterization of Transparent Oxyfluoride Tellurite Glass-Ceramics Containing CaF_2 Nanocrystals
Z.X. Hou, H.X. Li, S.H. Wang, M.H. Wang and X.D. Hu 305

Influence of Electrolysis and Plasma Polishing on Surface Properties of SUS304 Stainless Steel
X.M. Zong, J. Wang, Y.F. Wang and J.F. Liu 308

Effect of Initial Concentration of Cu^{2+} on the Adsorption Performance of Hydroxyapatite
Y.T. Guan, S.H. Wang, M.H. Wang, Z.X. Hou, X.D. Hu, H. Wang, H.L. Fan and N. Zhang 312

$Li_{0.95}Na_{0.05}Ti_2(PO_4)_3$/C with Good Performance as Anode Material for Aqueous Rechargeable Lithium Batteries
J. Zhu, Y.G. Liu, Q.Q. Tian, L. Wang and J.L. Cao 316

Effect of Melting Temperature on Microstructure of *In Situ* TiC/Al Composite and Formation Mechanism of TiC
H.L. Yuan, Z.H. Zhou, Z.H. Wang, Z.J. Zhong, X. Zhang and X.F. Xue 320

Effect of Cr on Microstructure and Mechanical Properties of Al–3.2Mg Alloys
Z.J. Zhong, Z.H. Zhou, Z.H. Wang, X. Zhang, H.L. Yuan and X.F. Xue 325

Research on Preparation of Aluminum-Metal Coating and its Microstructure by Melting-Casting
X.F. Xue, Z.H. Zhou, Z.H. Wang, J. Shao, H.L. Yuan and Z.J. Zhong 331

Research Progress of Graphene-Based Composites in Supercapacitor
Z.X. Hou, G.B. Li, S.H. Wang, M.H. Wang, X.D. Hu, Y. Zhou and S.M. Li 337

Dielectric Barrier Discharge Plasma Reduced Pt Catalysts Supported on Activated Carbon and their Electrocatalytic Activity
L.B. Di 340

Preparation of Au/P25 Catalysts for Removal of CO by Dielectric Barrier Discharge Plasma
L.B. Di 344

Kinetics of Inverse Emulsion Copolymerization of Dimethyl Diallyl Ammonium Chloride and Acrylamide
X.N. Wang, R.Z. Zhang and N.S. Jin 348

Research of Formation Mechanics on Nanostructured Chips by Multi-Deformations Based on Finite Element Method
C.L. Wu, Z.R. Wang and W. Zhang 352

Single Frequency LD-Pumped 2.09 μm Cr, Tm, Ho: YAG Microchip Laser
Y.M. Nie, Y.K. Guo, X. Ding and M.M. Guo 356

Review and Prospect on Tear Damage Research for High-Performance Flexible Fiber-Reinforced Composite Material
S. Cao, L.B. Liu, H.D. Xiao and M.Y. Lv 360

Influence of Volume Fraction of Piezoelectric Ceramics on Poperties of PZT672/Epoxy1-3 Piezocomposite
B. Zhang, L.K. Wang, L. Qin, C. Zhong, D. Long and J.J. Liu 364

Luminescence Properties of Rare-Earth Co-Doped Phosphate Glasses for White Light Emitting Diodes
G.H. Chen, X.L. Kang and Y. Yang 369

Monolithic Porous Graphene/Poly(Vinyl Alcohol) Gels: Preparation, Structure and Dye Adsorption
P. Wang and Y.P. Guo 373

Research Progress for High Strength Structural Steel and Key Issues of Application in Seismic Zone
L.X. Ji and T. An 379

Luminescent Properties of $Ca_{1-x}Ba_xSnO_3$: Eu^{3+}, Dy^{3+} Composites Prepared by Coprecipitation
L.M. Dong, F. Lv, Q. Li, Z.D. Han and X.Y. Zhang 383

Study of Dislocation Densities of Thick GaN Films
Y.G. Li, X.Q. Xiu, X.M. Hua, S.Y. Zhang, S.P. Gu, R. Zhang, Z.L. Xie, B. Liu, P. Chen, P. Han and Y.D. Zheng 387

The Luminescence Properties of Green YPO_4: Tb^{3+},Ce^{3+} Phosphors for WLED
J. Li, L.M. Dong, Q. Li and Z.D. Han 391

Preparation and Luminescent Properties of Single White $Ca_2MgSi_2O_7$: Eu^{3+}, Ce^{3+}, Tb^{3+} Phosphor for WLED
X.Q. Zhang, L.M. Dong, X.C. Tang, Q. Li and Z.D. Han 395

The Temperature Control of the Preheating Tank in the Procedure of Chloroacetic Acid's Crystallization
Z.F. Wang, C.Y. Liu, X.L. Song and Y.X. Gao 399

Effects of $SnCl_4$ Concentration on the Properties of Electroless Deposited Ni-Sn-P Coatings

A New Type Aluminum Alloy Backup Frame of FAST Project
B.Q. Zhao, Q.M. Wang, Q. Zhao, X.D. Gu and J.W. Hu 701

Changes in Water Adsorption Desorption Isotherms of Cement Mortars Caused by Carbonation Coupled with Humidification-Drying Cycles
T.P. Son 705

Research Progress of Sintered Wall Material Products Synchronous Cutting Machine
H.M. Liu, C.Q. Wu, X. Zhang and Y.B. Xu 710

The Higher Order Crack Tip Fields for Anti-Plane Crack in Linear Functionally Graded Piezoelectric Materials
Y. Dai, X. Chong and S.M. Li 715

The Crack Tip Fields for Anti-Plane Interfacial Crack between Functionally Graded and Homogeneous Piezoelectric Materials
Y. Dai and X. Chong 719

The Preparation and Detection of Quality Standard about Houttuynia Spray
T. Xia, Q.D. Chen, J.K. Wang, J. Zeng and J.Y. Guo 723

Ethylene Oligomerization by Ni(II) Complex Based on Peptide
W. Bai, C.G. Cao, H.X. Pei, K.H. Hu, H. Zhou, M. Peng, T. Jiang and J.Y. Dong 727

Synthesis of Nickel(II) Complexes and its Application to Ethylene Oligomerization
J.B. Kou, S.N. Zhao, C.G. Cao, H. Zhou, K.H. Hu, M. Peng, G.S. Su, T. Jiang and J.Y. Dong 731

***In Situ* Formation of Insect Repellent Delivery System**
D.R. Lin and L.J. Hu 735

Structure of Bridged Silsesquioxane Material Bearing a Pendant Dodecylamine
D.R. Lin and L.J. Hu 739

Hedgehog Buckyball: High-Symmetry Complete Polyhedral Oligomeric Silsesquioxanes (POSSs) Characterized by UV-MALDI-TOF Mass Spectrometry
D.R. Lin and L.J. Hu 743

Effect of Temperature on the Growth and Biochemical Composition of *Sargassum muticum*
C.Y. Yuan, S. Yang, Y. Wang and Q.M. Cui 747

Numerical Simulation of Cr12MoV Steel during Quenching Process
W. Zhang, Z.D. Qu, X.H. Deng and X.W. Duan 751

Effect of NH4Cl Flux on Structural and Luminescent Properties of CaS: Eu^{2+} Phosphors
Y.J. Zhang, J. Zhao, D.J. Wang and J. Ma 755

Preparation and Properties of Multi-Elements Doped Perovskite-Type Mixed Conductors for IT-SOFC Cathodes
J. Fu, J. Zhao, Y. Fu and R.R. Li 759

Research on Microstructure and Properties of Plasma Powder Spray Welding Layer Based on 3D Printing
E. Meheretu, Z.M. Wang and H.C. Han 763

The Bioactivity of Gradient Composite Bioceramic Coating with Two Kinds of Rare Earth Oxide Fabricated by Wide Band Laser Cladding
P.Z. Jiang, Q.B. Liu, L.Y. Zhang, H.B. Jiang and Z. Zhang 767

Discussions on the Pretreatment of the Air-Conditioning/Cotton Blended Fiber – The Application of Tea Saponin
Y.J. Zhang and Y.Y. Zhang 771

Effect of Mixed Multiple Rare Earth Oxide on the Microstructure of Bioceramic Coating Prepared by Wide Band Laser Cladding
Z. Zhang, Q.B. Liu, L.Y. Zhang, H.B. Jiang and P.Z. Jiang 775

The Chemistry Model of Ion-Ion Interaction Energy of Full Ionized Hydrogen Plasma
L.S. Guo, X.R. Zheng and Z.R. Wu 779

Study on Catalyst for Catalytic Ozonation to Leachate and Catalytic Process
B.J. Jiang, Z.J. Tian and J.M. Jiang 783

Carbon Nanotubes-Assisted Fabrication of TiO_2 Nanocomposite Film for Optimum Electrochromic Application
S.P. Liu, W. Wang, L.L. Cui and H.N. Guan 789

Evaluation the Effect of Anti-Oxidation of Chondroitin Sulfate
L.P. Xu and X. Wang 793

On Pretreatment Experimental Study of High Strength Gypsum by Yunnan Phosphorus Gypsum
S.C. Quan, Z.M. Zhao, R. Tian and S. Han 797

Research on the Treatment of the Yellow River Micro-Polluted Water in Shanxi by Ozone-Activated Carbon Process
X.B. Tang, J.F. Zou, K.F. He, J. Liu, J.J. Zhou, F.J. Wang, Y.X. Yuan and J.G. He 803

Dye Adsorbent Prepared by Crosslinking of Poly(γ-glutamic acid) and Gelatin
W. Wang, S.P. Liu, H.N. Guan, J.Z. Liang and C. Tan 809

Study on the Growth Model of Expandable Graphite
F. Ye, C.G. Zhu and Z.H. Zhang 814

Coupled Hydrogen and Oxygen Isotope Analyses for the Mainstream of Poyanghu Lake (Jiangxi Province) and their Environmental Implications
D.R. Lai, A.D. Wang, C.G. Li, Y.P. Chen, Z.B. Yan and J.J. Wan 820

Experimental Study the Affection of the Dust Emission on Sand Stockpile by the Height of Windbreak Wall and Wind Speed
Z.Q. Liu, L.Y. Ma and X.Y. Zhao 823

Adsorption Removal of Phosphorus from Wastewater by Steel Slag Filter Material
J.T. Wang, Y.Z. Yu and L.L. Gao 827

Simulation of Vapor Absorption of Aqueous Libr Solution on Alternate Heat and Mass Transfer Surfaces of Corrugated Plates and Mesh Pecking
R.B. Cao, Y.P. Chen and J.F. Wu 831

A Novel Multilayer Structure with Frequency Selected Surface for Electromagnetic Compatibility
J. Li and D.L. Xu 837

Study on Processing Technology of Brewer's Grains on Acid Dye Brilliant Cresyl Blue Wastewater
Y.H. Jiang, X.L. Jiang and C.G. Cai 841

A New Harmless Disposal Method of Aluminium Phosphide Residue
X.C. Wang, D. Li, S.L. Duan, D.B. Li and X.L. Qi 845

Experimental Study on Sewage Treatment by Vortex-Grid Flocculation Technology
F.P. Hu, H.H. Li, L.Y. Wang, Z.G. Tong, Q. Zhang and H.L. Dai 849

Study on Removing Atrazine and Chlorothalonil in Raw Water in Reservoirs in North China by PAC Adsorption and Enhanced Coagulation
J.F. Zou, X.B. Tang, M. Yu, J.J. Zhou, F.J. Wang, J.G. He and Y.X. Yuan 853

Modified Reduced Graphene Oxide with Enhanced Solubility and Conductivity and its Application
X.P. Zeng 859

Aero-Optical Effects of Mc=0.5 Supersonic Mixing Layer
L.F. Tian, S.H. Yi, Y.Z. Zhu, Y.X. Zhao and L. He 863

Simulation Realization of Frequency-Variable and Speed-Adjustable System Based on Vector Control
Y. She 867

Research Status and Application Prospect of Deep Cryogenic Treatment Technology on Cemented Carbide
T.H. Guan, H.M. Liu, Y.B. Xu, C.Q. Wu and Y. Lv 871

Chapter 2: Applied Mechanics, Construction and Testing Technologies

The Fatigue Performance Evaluation of Pressure Vessel Steel Using Modified Staircase Method
H. Xue, R.F. Li, L.X. Wu, W.J. Peng and J.Q. Huang 879

The Welding Residual Stress Analysis on High Performance Bridge Steel with Different Testing Method
H. Xue, R.F. Li, L. Yu, D. Liu and W.J. Peng 883

A Study on the Sample Overheat Phenomenon of Fatigue Test
H. Xue, J. He, J.Q. Hu, L.X. Kuang and W.J. Peng 887

Numerical Simulation Study of Stress-Magnetization Effect on Different Notch Steel Specimens
X.W. Xi, S.K. Ren and Y. Huang 891

Study on Factors of Axial Crushing of Thin-Walled High-Strength Steel Sections Used in Passenger Car
G.F. Zhao, Y.W. Hu, X. Cheng and K. Xiao 898

Study on the Borehole Stability in Liulin Coal Reservoirs
L.Y. Song, L.J. Xiao, J.W. Wang, J. Zhang and T.L. Zhuang 903

An Improved CEM with Regard to the Crack-Tip
Y.S. Lin 908

Efficiency Prediction of Limestone-Gypsum Wet Desulphurization Based on Support Vector Machine
J.M. Yang, B.S. Sun and N.Z. Qi 913

Research on Failure Mechanism Consistency in Accelerated Wear Test of Metal Materials
X.B. Ma and B. Cheng 918

Stability Analysis of Single-Pier Variable Cross-Section Box-Girder Continuous Bridge
G.S. Yin, J. Bai and J.J. Feng 923

Effect of Convex Platform on Stress Distribution in Nickel-Based Superalloy Plate Produced by Vacuum Countergravity Casting
C.M. Zou, S.Q. Su, H.W. Wang and Z.J. Wei 927

Calculation about Stress Concentration Coefficient of Welded Cruciform Joints of Magnesium Alloy Based on FEM
B.L. He, Y.X. Yu, X.D. Zhang and S.S. Xia 931

Finite Element Calculation about Stress Concentration Coefficient of Welded Butt Joints of Magnesium Alloy
Y.X. Yu, B.L. He, X.D. Zhang and S.Y. Lei 935

Effect Study of Water on the Mechanical Behavior of Gangue in Chongqing Tongliang Mine
Y.J. Zang 939

Experimental Research on Tensile Strength of Out-of-Plane Composite Joints for Integrated Composite Cabins
D.H. Zhang, X.H. Zhou and L.W. Zhou 943

Modeling and Simulation Analysis on Building Temperature and Toughness
Q. Zhang 947

Relationship Modeling between Tensile Strength of Steel Building and Temperature
Q. Zhang 951

Study on the Affects of Partition of the Parallel and Cross Tunnel Adjacent Construction
W. Zheng and L. Gao 954

The Application of MASW Method on the Studying of the Vibrations in Civil Engineering
K. Luo 958

Experiment Research on Mechanical Properties and Penetration Performance of UHMWPE Fiber Concrete
Y.W. Zhang, L.H. Yan, L. Zhu, S. Zhang and L.F. Li 961

Treatment of Simulated Acid Mine Drainage by Permeable Reactive Barrier: Column Study
C.F. Cai, F.Z. Qi, X.L. Lin and L. Jiang 966

New Method to Predict the Bearing Capacity and End-Bearing Ratio of Friction-Type Long Pile
Z. Qian and K.H. Wang 970

Research on the Succession of *Artemisia ordosica* Community in Mu Us Sandy Land
J.H. Zhang 975

Research on Performance of Coupled Heat Pump System with Different Backfill Material
J. Liu 978

Numerical Simulation of the Kinetic Energy Projectile Oblique Penetration into the Concrete
J. Chen and X.J. Ye 982

Analysis on Aerostatic Stability for Jianghai Direct Ship Channel Bridge in Finished Stage
L. Yu, S. Wang, Y.Y. Che and G.H. Zhao 986

Chapter 3: Bio- and Medicine Research

Spectrophotometric Method for the Assay of Norfloxacin Lactate
Y.H. Lei 993

Co-Expression of Threonine Dehydratase and Acetolactate Synthase in Escherichia Coli for L-Isoleucine Production
J. Wang, J.K. Sun and Q.Y. Xu 997

Developing a Sensitive Reporter System for Monitoring of Pancreatic and Duodenal Homeobox Gene 1 (Pdx1) and Neurogenin 3 (Ngn3) – Mediated Transdifferentiation from Human Hepatic Cells into Insulin-Producing Beta-Like Cells
C. Xie, W. Donelan, S. Lu and L.J. Yang 1003

A Method for the Determination of Atropine in Pharmaceutical Preparation Using CE-ECL
Q. Xiang, X.D. Yang and Y. Gao 1007

Effect of Natural Clarifying Agents ZTC1+1 II on Purification of *Angelica* Polysaccharides
C.L. Li, Y. Men, L. Yang, A.M. Yang and Q. Shang 1011

Effect of Ginkgo Biloba Extract on Contractility Enhancement of Diaphragm of Rats with Type 2 Diabetes
X.S. Li, R.Y. Wu and Y. Hu 1015

Study on Degradation of Radix Isatidis Polypeptide in Artificial Gastrointestinal Environment
N. Nan and X.J. Liu 1020

Repetitive-Element PCR Technology for Identification of Mulberry Pathogens
G. Li, H.Z. Song, J. Wang and F.A. Wu 1025

Optimum Process for Extraction of Total Flavonoids from Castor Leaves by Orthogonal Test
Y.H. Jiang, X.L. Jiang and C.G. Cai 1029

Comparative Bioenergetics of Diploid and Triploid Pacific Oysters *Crassostreas gigas* at Different Temperatures
X.Y. Li and Z.M. Zhou 1033

Prognostic Significance of Glycoprotein 96 in Human Hepatocellular Carcinoma
X.P. Wang, H.P. Lin, B. Xu, K.P. Zhang, J.G. Fang and Y.X. Yang 1037

An Evaluation of the Potential for Pharmacokinetic Interaction between Tramadol and Cytochrome P450 2D6 Inhibitor Promethazine
P. Liu, L. Sun, J. Zhang and R.C. Guo 1041

Effect of Crude Polysaccharides from *Discorea bulbifera* L. on the Liver in the Mice Bearing U14 Cervical Carcinoma
H.X. Cui 1044

Design, Synthesis, and Biological Evaluation of Sorafenib Analogs Bearing a Sulfonylurea Unit as Novel VEGFR2 Kinase Inhibitors
W.F. Zhu, C.J. Wu, S. Xu, W. Li, H.H. Fang, Z.C. Chen, X.H. Tu and P.W. Zheng 1048

The Effects of the Film Made by Citral β-Cyclodextrin Inclusion Complex Combined with Chitosan on Fresh Beef
H.J. Chen, F.X. Yang, L.J. Ou, D.X. Zhou and L. Li 1052

Polysaccharide from Eucheuma Gelatinae Enhance Immunocompetence against Murine H22 Tumor *In Vivo*
J. Tang, Z. Kong, D.Y. Liu and A.J. Liu 1056

Analysis of Paclitaxel in Pharmaceutical Injection by Ultra Performance Convergence Chromatography
X. Gong, X.B. Huang, Y.H. Wei, N.L. Qi, L.J. Lin and Y.Y. Liu 1060

Study on the Genotoxicity of Organic Extracts of the Water from a Reservoir by Using Comet Assay
J.T. Wang, Y.Z. Yu and X. Li 1064

Wireless Power Transmission System of Radio-Telemetry System for Physiological Parameters Detection
Z.W. Jia, H.R. Ren and G.Z. Yan 1068

Study on Degradation of Traditional Chinese Medicine Wastewater with Cu/Cu_2O Composite Photocatalyst
C.H. Yuan 1073

Design Consideration of a Health-Information-Technology-Supported Intelligent Urinalysis System
T. Dong 1077

An Improved Medical Image Fusion Method Based on Nonsubsampled Contourlet Transform
Y.C. Yang, J.W. Dang and Y.P. Wang 1082

Interactive Medical Image Segmentation Method with only Positive Label Examples
C.G. Zhang, Y. Zhang and X.H. Zhang 1088

The Influence of Perceptual Load on Inhibition of Return
X.J. Liu, Z.H. Fan and J.Z. Zhou 1093

The Design and Application of the Information Management Platform for the Prevention and Control of AIDS on the Basis of the Residents' Health Records
S.H. Shi and S.W. Xiong 1097

Mobile Nurse Information System with Efficient Physiological Monitoring for Patient
F. Wu and H. Wang 1103

College Female Students' Physical Health Evaluation Index Correlation Research Based on the PDCA Cycle Model
J. Shou 1107

The Risk Factors for Pediatric Care and Preventive Measures
L.B. Liu 1111

Design and Evaluation of the Primers for Rift Valley Fever (RVF) Virus RT-PCR Detection
Z.X. Yang, B. Wang, Q.M. Xu, X.P. Yao, L. Zhu, Z.W. Xu, K.Y. Wang, G.L. Li, S.Z. Peng and Y. Wang 1115

Detection on the Pulse Signal of Human Body Based on Piezoelectric Impedance Technique
J. Zhang, B.Z. Guo and H.M. Tang 1120

Chapter 4: Resource, Energy and Electronic Development, Environmental Engineering

The Making of Mathematical Models for Ecological Cities
Y. Xu 1127

Multilayer Architecture on Urban Public Crisis Decision Support System
Y.C. Ren 1131

Accurate Calculation Receiving Power of the Electromagnetic Wave Scattering between Two Stations on Sea Surface
X.M. Li, T.L. Dong and G.M. Huang 1135

Simulation and Analysis for Damage of Certain Electrical Power Equipment in Battlefield
X.Y. Yang, Q.S. Ma, P.Y. Cheng, Q. Zhang and L. Zhang 1141

Application Research on Technique of Re-Entry Old Wells in Sulige Area
Y.F. Xue, Z.Y. Zhu and D. Li 1146

Unsteady Heat Transfer Analysis: Saving-Energy and the Regionalism Design on Air-Conditioning System for Car
L. Ouyang and D. Li 1150

Constructing of Low Carbon Ecological Index System for Planning: Liaobin New Town as an Instance
J.C. Yuan, S. Chen, M.Z. Huang and L. Fang 1157

Ballast Water Discharge and the Influence of Seawater Environment
X.Y. Li, S. Liu and Z.M. Zhou 1161

A High-Order CMOS Bandgap Voltage Reference
Q.N. Zhou, Y.S. Li, J.Z. Lin, H.J. Li, C. Li, Y. Pang, G.Q. Li, X.M. Cai and Q. Li 1165

Multistage Amplifier Using Dual-Miller with Nulling-Resistor and Dual-Feedforward Structure
Q.N. Zhou, Q. Li, J.Z. Lin, H.J. Li, C. Li, Y. Pang, G.Q. Li, X.M. Cai and Y.S. Li 1169

Photovoltaic Inverter Output Current Research of Adaptive Active Harmonic Compensation Device
F.J. Chang, H.Q. Ma, C. Cui and J. Zhang 1173

A New Optimal Method for Load Transfer in Power Distribution Network
Q. Wang, L. Yao and Z.L. Zhang 1177

Reliability Evaluation for Distribution System Including Protection System Failures
Z.L. Zhang, L. Yao and Q. Wang 1181

The New Technology of PV Power Generation System Based on Extremum Seeking Control
J.Y. Shi, K. Zhang and Y.G. Zhang 1185

Evaluation of the Yangtze River Littoral Wetland Soil with Total Organic Carbon
Z.W. Luo and X. Wang 1189

Public Greenbelt Layout Optimization for Ecological Civilization City Construction
C.G. Chang, M.H. Qi, W. Li and K. Yin 1192

Design, Simulation and Experiment of Polarization Transformers Based on Twisted Chiral Metamaterials
Z. Yang, Z.S. Jing, Q.Y. Su, G.W. Qin and Z.L. Zhou 1196

The Research of Atmospheric Pressure Cold Plasma Jet Generated by Auto-Excited-Pulsed DC Discharge
Y.L. Hu, Q. Wang and Z.Q. Chen 1200

The Research of Hybrid Genetic – Particle Swarm Optimization Algorithm Based Reconfiguration of the Electric Distribution Network
X.N. Zhou, D.P. Ke, Y.Z. Sun and L.Y. Xu 1204

Effects of Geomembrance on the Contaminant Transport in Compacted Clay Liner System
J.J. Fan 1208

The Higher Order Crack-Tip Fields for Anti-Plane Crack in Exponential Functionally Graded Piezoelectric Materials
Y. Dai, X. Chong and S.M. Li 1212

The Effects and Countermeasures of Low-Carbon Economy on China's International Competitiveness of Industries
J.B. Hu 1216

The Application of Transformer Protection in 220KV Substation
W.L. Peng, W.L. Bian and M. Wang 1220

Analysis of Data Center Power System
H. Song and Z.T. Wang 1224

Urban Ecological Environmental Quality Evaluation System Research
X.X. Li 1228

Eco-Environmental Construction in Zhengzhou
X.X. Li 1232

The Influence of Lanzhou Reach of Yellow River to Temperature-Humidity Effect on Surrounding Lawn and Brick Underlying Surface
G.C. Liu, Y. Huang and S.Q. Gao 1236

Study of Morphological Changes Induced by Man-Made Coastal Project
T. Xu 1240

Simulation of Salinity Changes Induced by Man-Made Sea Embankment
T. Xu 1244

Forecast of Energy Consumption and Carbon Emission of Urban Traffic by Using System Dynamics
Y. Zhang, L.J. Wan, L. Zhang and D.X. Cheng 1248

Study on Feasibility of Concentrated Activated Sludge Reflow of Biochemical Pool of Small-Sized Wastewater Plant
Y.C. Guo and Y. Chen 1252

Analysis on Fluctuation Characteristics of Wind Power
Y. Wang 1256

Partial Discharge Characteristics Research Based on RVM
Y.H. Meng, H.Q. Li and Y. Hu 1260

Regional Water Resource Utilization Evaluation and Influential Factors Analyses
Y.Y. Wang and X.P. Hu 1264

Mineralizaton Process of the Bauxite in WZD Area
T. Cui 1269

Inhibiting Effect of Nonlinear Shielding Layer on Electrical Tree Propagation inside Insulation Layer of High-Voltage Cable
C.M. Li, B.Z. Han, L. Zhao and C.P. Yin 1273

The Power Supply Area Divided Based on Improved Voronoi Diagram
L. Liu, X.B. Tang, C.H. Zhao, Z.Y. Sha and X. Chen 1278

Investigation on the Energy Efficiency of Innovative Hybrid Impact Hydroforming
S.H. Wang, L.H. Lang and L.J. Lin 1282

Investigation on Nutrient Loads of Lake Taihu in China
H. Wang, K. Xia, B. Li and Y.Y. Zhou 1286

The Soil Enzyme Activities with Age of Tea in Three Gorges Reservoir Area
L.P. Zhang, G.M. Jia and Y. Xi 1292

Temperature Effect on the Hypergene Mineral Formation Process (The Case of Tailing Dumps of Komsomolsky Tin-Ore District)
V. Zvereva, A. Kostina and K. Frolov 1297

Evaluation of Technogenous Processes Proceeding in Tailing Dump of the Central Concentrating Mill of Dal'Negorsk District and their Effect on the Hydrosphere with Method of Physicochemical Modeling
V.P. Zvereva, A.I. Lysenko and A.M. Kostina 1301

Some Ecological Problems of Development of Mineral Raw Materials in Amurskaya Oblast'
L.T. Krupskaya, V.P. Zvereva and O.O. Panfilov 1305

Study on Sewage Treatment Process in Stone Production
M. Zhao, W.W. Guo, Q. Xiao and J. Zhang 1309

Accumulation of Chromium in *Vetiveria zizanioides* Assisted by Earthworm (*Eisenia foelide*) in Contaminated Soil
K. Zhang, Q. Chen, H.B. Luo and X.T. Li 1313

Study on Response of *Cyperus alternifolius* to Cr(VI) and Ni Combined Pollution
M.C. Liu and W. Zhou 1319

A Research of Environment Management Policy Based on the Externality Theory
H.C. Che and F. Cao 1324

Research on the Simulation and Realization Approach of Urban Low-Carbon Transport
X.L. Gao, T.J. Hu and P. Peng 1328

The Spatial Effect Identification of Pollution Treatment Investment in China
L.X. Huang and M. Liu 1333

Characteristics of Heavy Atmospheric Particulate Pollution under Beijing Fog and Haze
J.X. Liu, P. Yang, A.G.D.M. Liu and J. Liu 1338

Urban River Water Purification Experiment by Strengthening Ecological Engineering Methods
S.H. Yin, Y.C. Wang, W.Q. Peng, Y.L. Du, B. Gao, J.J. Gao, H.D. Zhou, Q.Y. Meng and Q.J. Li 1341

The Combinatorial Prediction about Chaotic Times Series of Natural Circulation Flow under Rolling Motion
C. Yuan, Q. Cai, G. Liu and F. Yan 1348

A Rapid Determination Method of ^{40}K Concentration in the Soil
W.W. Lu, H.G. Yue, J. Li and Y.X. Zhang 1352

Effect of Hg in Jiaozhou Bay Waters-Settling Process
D.F. Yang, F.Y. Wang, H.Z. He, Y.F. Wu and S.X. Zhu 1356

The High Resolution Sequence Stratigraphic Isochronous Framework in Threezhao Peripheral Zone
Z. Na, C.Z. Liu and P. Li 1359

Use Horizontal Aeration Method to Treat Organic Pollution in Soil
L.Y. Xu 1364

Study on Identification Method of Fructus Lycii Origin by Mineral Elements
Y.P. Pang, K. Liu, Z.L. Zhao and X.T. Li 1368

Establishment of Models for Tight Sandstone Formation Evaluation in the Ordos Basin of Northwest China
X.L. Wei, J. Li, R. Xu and L.L. Zhi 1372

The Research and Application of Multiple Collaborative Anti-Sloughing Drilling Fluid
M.T. Jiang, H.Y. Wei, Y.H. Li and W.Z. Shi 1376

Vertical Zonation in Penecontemporaneous Period of the Bauxite in WZD Area
T. Cui 1380

Preservative Features of the Fossils in Bauxite Deposit of WZD Area, Northern Guizhou, China
T. Cui 1384

Characteristics of Interlayers in Bauxite Deposit of WZD Area, Northern Guizhou, China
T. Cui 1388

Research Progress of Bauxite in WZD Area, Northern Guizhou, China
T. Cui 1392

Evaluation Method of Coral Reef Integrity: RMDI and Coring Rate Comparative Analysis Method
J.C. Wang, C.Y. Wang and Z.Q. Han 1396

Special Structure and its Geological Significances of WZD Bauxite
T. Cui 1400

Analysis on Oxidized and Reduced Conditions in Penecontemporaneous Period on the Bauxite in WZD Area
T. Cui 1404

Beneficiation of a Low-Grade Barite Ore in Myanmar
T.T. Li, S.Q. Liu, Y. Zhao and H.J. Wang 1408

Research on the Flotation of Low Grade Copper-Nickle Ore
Z.B. Deng, T. Xiong, X. Wang, Q.Y. Zhao, X. Xie and X.W. Lv 1411

Concentration and Distribution of Cr, Pb and Zn in the Jurassic Coals from Northern Shaanxi and Ningxia, China
H. Wang, M.L. Du and G.T. Zhang 1415

The Quantitative Model Research of Impact of Water Level Changes on Channel Capacity
T. Liu, L. Yao and C. Zhao 1419

Porosity Inversion under the Sequence Stratigraphy Framework
W. Yang and M.Y. Hu 1424

Analysis on Acidity and Alkalinity of Metallogenetic Environment in Penecontemporaneous Period on the Bauxite in WZD Area, Northern Guizhou, China
T. Cui 1428

Chapter 5: Advanced Technologies in Modelling, Simulation and Optimization, Computation Methods and Algorithms, Intelligent Engineering Applications

An Optimal Algorithm for Estimating Fundamental Matrix by Removing the Outliers
L.Q. Guo, J.B. Liao, F.P. Zhong, X. Yu and J. Tao 1435

Complex Network Optimization Research of Personalization-Based Recommendation Algorithm
C.X. Gao and C.P. Qi 1441

Algorithm Study and Application of Personalized Intelligent Recommendation Engine
G.L. Pu 1445

Research on Marine Fuel Boiler Drum Water Level Model and Dynamic Analysis
M. Zhu 1449

Studies on Broad-Sense Sample Method in Data Mining
Y. Tang 1453

The Application of Maximum Differential Algorithm in Adaptive Ocean Sampling
Y. Wang, C.S. Wu and Y.Q. Shi 1456

Parameter Estimation for Wiener Systems with Preload Nonlinearities
Y.X. Ni and J.D. Cao 1460

A Vertical Handoff Decision Algorithm Based on QoS Evaluation
Y. Tao and K. Zhou 1464

A Video Digital Watermarking Algorithm Based on Chaotic Maps
Y.W. Li 1469

Zero Watermarking Method Based on Enhanced Bit-Plane
J. Zhao, B.F. Yang and X.Y. Wu 1473

Research on Simulation of Modern Storage System with Flexsim
Q.T. Han 1477

Study on Application of Vendor Managed Inventory Model
Q.T. Han 1481

Research on Material Inventory Model and Application
Q.T. Han 1485

A Fuzzy Clustering Algorithm of Automatic Classification Based on EnFCM
H.W. Han, L. Tian and J.Q. Miao 1489

Knowledge Representation of Art Patterns Based on the Calculation Mental Image
S.R. Kuang 1493

Improved Software Cost Estimation Method Based on COCOMO Model and Linear Regression
H. Yang 1497

Research on Improved Staged Software Cost Estimation Method Based on COCOMO Model
H. Yang 1501

Analysis of Knowledge Fusion System Model Based on Ontology and Multi-Agent Theory
L. Lei and M. Zhang 1505

Research on Classification and Encoding of Digital Cultural Relics
L. Lei and M. Zhang 1509

An OCL-Based Formal Model for Cloud Forensics
J. Wang, Z.M. Tang and X.L. Jin 1513

Research on Customers Churn Prediction Model Based on Logistic
M. Jiang, N. Chu and X.M. Bi 1517

Site Selection of Customer Operation Center for Pull and Drag Transportation Based on the Analytic Hierarchy Process
X.Q. Luo and X.Y. Yin 1522

Research on the Layout of Integrated Freight Hub Based on Two-Stage Model
Y.Y. Chen and T.X. Liu 1526

The Optimization of Logistics and Distribution
W. Xiong and L.Y. Zhang 1532

Research on Rough Set Theory-Based Customer Division
G.J. Song, X. Cao and X.Y. Wang 1536

A K-Nearest-Neighbour Based Classifier for Securities Text Categorization
T.B. Liu 1541

Research of Intelligent Warehouse Layout Base on Genetic Algorithm and Dynamic Programming
L.Q. Yang and Q. Yan 1547

A Generalized Attributes Significance Measure Method
F.C. Li, M. Li and S. Liu 1551

A Fusion Method of Point-Cloud Based on Parallel Estimation of Distribution Algorithm
Z.T. Jiang, L. Zhou and L. Zhou 1555

Bacteria Genome Compression Based on the Weighted Context Model
M. Chen, X.M. Jia and L. Liu 1561

Research on Blind Source Separation Algorithm Based on Particle Swarm Optimization
H. Zhou, C.Z. Chen, X.M. Sun and H. Liu 1566

The Data Mining Technology of Particle Swarm Optimization Algorithm in Earthquake Prediction
X.Y. Zhang, X. Li and X. Lin 1570

An Improved Weighted Centroid Localization Algorithm Based on RSSI
C.L. Liu and Z. Li 1574

A Parallel Implementation of the K-Means Algorithm Based on MapReduce
W. Yan, J. Zhou, Q. Huang and L. Shi 1578

A Inflexion Nonlinear Global Particle Swarm Optimization (PSO) Algorithm
L.X. Lv and X.Y. Lin 1582

The Research of Improving Clothing Crossing-Selling Based on Apriori Arithmetic
C. Zhang, Y. Liu, F.S. Sun and L. Yao 1586

Research of Propagation Behavior on Tibetan Network Public Sentiment
Y.X. Li, A.L. Wu and Y.N. E 1590

Research on Anti-Plagiarism in the Education Informatization Background
B. Fu and B.G. Xie 1594

Towards the Evaluation of Suffix Trees
X.P. Wang 1598

Research of Geomagnetic Matching Algorithm Based on Artificial Fish Swarm Searching Strategy
X. Li and Z.L. Zhu 1602

Given the Principal Disjunctive Normal Form of Simple Proposition Formula
Z.J. Chen, H.Z. Shi and Y.J. Liu 1607

Online Long-Term Object Tracking Based on Compressed Haar-Like Features via Sparse Representation
M. Zhao, L.P. Wang and L.P. Zhang 1610

A New Virtual Visual Servo Algorithm
M. Li, X.N. Wang and J. Zhu 1615

A Path Planning Algorithm Based on the CNN Model under the Curvature Constraint
S.J. Wang, X.N. Wang and J. Ping 1621

Niche Brain Storm Optimization Algorithm for Multi-Peak Function Optimization
H.J. Zhou, M.Y. Jiang and X.Y. Ben 1626

Research on the Validation Method of Product Data Quality
P. Wang and B. Wang 1631

Stock Price Prediction Model Based on IWO Neural Network and its Applications
H. Liu and X.Y. Lv 1635

An Interval Slope Approach to Fuzzy C-Means Clustering Algorithm for Interval Valued Data
Y. Jin and J.H. Ma 1641

Stock Price Prediction Model Based on BA Neural Network and its Applications
X.Y. Lv, S.L. Sun and H. Liu 1646

A Fast Locating Algorithm of Vehicle License Plate under Complex Scenes
Y. Lei and Y. Zhang 1652

A Multidimensional Model of Data Warehouses
Z.Y. Chen and T.X. Zhao 1657

Architecting Service-Oriented Publish/Subscribe Applications: Data Model and Matching Algorithm
B. Dong 1660

Research on Psychology Data Clustering Algorithm Based on CUDA
L.L. Dong, Z.S. Ma, W. Dong and X. Zhang 1664

Cell Selection Algorithm Based on Coordinated Beamforming
Z. Liang, Y.B. Li and F. Ye 1671

Research on Sub-Band Synthesis Algorithm of MIMO-SAR
Y.A. Xie and Z.M. Tan 1676

Comprehensive Similarity Measurement Model Based on Three Algorithms
N. Liu, B.L. Long, X.K. Zheng, L.F. Han, T. Qu and B.J. Cui 1680

Mean Evolutionary Algorithm Based on Intermediate Value Theorem of Continuous Function
Y.C. Tan, C.S. Deng and Y. Liu 1686

Meta-Analysis and Evaluation of Visualization Support to Decision Trees Classification
Z.Y. Chen and T.X. Zhao 1692

Allocation Scheme of Short Training Sequence Based on OFDM-PON
S.L. Guo, X. Chen, C.X. Xu, Y. Jiang and Y.C. Li 1695

Three-Dimensional Yarns Modeling for Tufted Carpet Simulation
J.H. Li, G.F. Chen, Q.Q. Huang and X. Wei 1700

Decision Making Support Model for the Incident Emergency Management of Migrant's Group Based on CBR
D.H. Zhang, L. Cheng, R.W. Wu, J. Wang and J.Y. Liu 1704

Equivalent Integral Equations of the Static Schrödinger Equation by Variation of Constants Method
S. Zhang, B. Cai and D. Wang 1712

Kink-Type Solutions of the MKdV Lattice Equation with an Arbitrary Function
S. Zhang, Y.Y. Zhou and B. Cai 1716

An Improvement of the Method for Paraphrase of Chinese Double Negation
Z.J. Wang, S.J. Zhang, Y.F. Gao, Y.F. Lin and Z.J. Wang 1720

Water Fluid Simulation with an Improved SPH Method
X. Zhao 1724

Analysis of Convergence Rate for Improved Generalized Ant Colony Optimization Algorithm
D.Y. Zhang and H. Zhao 1728

Convergence Speed of Multi-Objective Generalized Ant Colony Optimization Algorithm
D.Y. Zhang and P. Fu 1732

The Applications Based on the Rough Set Theory Algorithms to Determine the Weight
N.N. Chen 1736

Takeoff Performance Algorithms Analysis of EFB Based on iOS
J. Lu, Q. Li, B.B. Zhao, F. Xiao and W.Y. Qiu 1739

Region Analogy-Based Quantization Method for Numerical Data
Y.D. Sun 1743

Application of Improved ANT Algorithm to Planning of Anti-Ship Cruise Missile Route
Y.T. Yu and Y. Ding 1747

Application of Improved Intuitionistic Fuzzy for Sea-Battlefield Situation Assessment
Y.T. Yu and Y. Ding 1751

Imbalanced Data Classification Using Cost-Sensitive Support Vector Machine Based on Information Entropy
W. Duan, L. Jing and X.Y. Lu 1756

Develop Local Fuzzy Classifier to Modify Low-Confidence Output of Global Classifier
P. Ling, X.S. Rong, Y.Q. Dong and G.S. Hao 1762

The Improved Algorithm about Binocular Vision of Flexible Structure in On-Orbit Modal Identification
Y. Zhao, J.B. Gao, C. Xu and C.F. Zhang 1766

An Algorithm of Uncertain Reasoning Considering Subjective Factors
Y.H. Han, K.T. Chen, H. Shao and L. Du 1770

A Fuzzy Clustering Algorithm of Web Customers Based on Attributes Reduction
H.X. Wan and Y. Peng 1775

The Application of Graph Model in the Cultural Archives
P. Sun 1779

Deobfuscate Non-Returning Calls and Call-Stack Tampering in Instruction Traces
J. Qiu, X.H. Su and P.J. Ma 1782

Constructing Attractors via the Improved Eugenics Genetic Algorithm
L.M. Du, F.Y. Wang and Z.Y. Han 1786

Comparison Results between Jacobi and USSOR Iterative Methods
T. Zhou and S.G. Zhang 1790

Convergence Results of the Improving Modified Gauss-Seidel (IMGS) Iterative Method for a Symmetric Positive Definite Matrix
S.G. Zhang and T. Zhou 1794

A Fast Algorithm for Computing the Determinants of the Heptadiagonal Matrices
X. Li and L. Yang 1798

Two-Parameter Conjugate Gradient Projection Method and its Application
H.F. Cui 1802

Generalized J Sets Based on Periodic Orbit and Attract Time
L.M. Du, F.Y. Wang and Z.Y. Han 1806

Static Fault-Tolerant Strategy for High Performance Computing Platform
Y. Sun and J. Liu 1810

Prediction of Mine Inrush Water Based on BP Neural Network Method
A.J. Shao, Q.X. Meng, S.W. Wang and Y. Liu 1814

Fuzzy Comprehensive Evaluation Model of Selecting Football Coach
C.J. Rao and J.H. Dong 1821

Calculation of Dynamic Stress Intensity Factor by the Boundary Element - Laplace Transform Method
W. Zhang 1825

Point Rupture Solutions of a Singular Quasilinear Elliptic Equation Arise from Non-Newtonian Fluids
Z.J. Cui, M.Y. Xu and R. Zhang 1829

Application of Ant Colony Algorithm to the Hierarchical Routing in Wireless Sensor Networks
L. Sang and D. Long 1833

Study on the Optimization of Data Mining in Big Data
G. Xin and H. Yan 1837

Design and Implementation of Instruction Expert System Based on Improved Genetic Algorithm
D.Q. Wu and S.S. Wang 1841

Investor Selection Model under Uncertain Information Environment
C.J. Rao and C. Wang 1845

A Novel Multiobjective Memetic Algorithm Based on IWO-DE and its Application in Nutrition Decision Making Problem
G.P. Wang, M. Zhang and W.W. Zhao 1849

An Improved Genetic Algorithm for Text Clustering
S.D. Yu, Y. Ding, X.C. Ma and J. Sun 1853

Applied Technology with a Modified Sixth-Order Convergent Iterative Method for Solving Nonlinear Equations
L. Fang, Y. Li, H.Q. Wang and R. Chen 1857

Research on Improved AES Encryption Algorithm
Z.H. Yang, N. Li, L.Y. Liu, R.J. Qi and L.L. Yu 1861

CMA Blind Equalization with Quasi-Newton Algorithm in Underwater Acoustic Channels Based on Simplified Cost Function
Y. Xiao and R. Ruan 1865

The CPML for Hybrid Implicit-Explicit FDTD Method Based on Auxiliary Differential Equation
Y.F. Mao, P.H. Huang and L.G. Ma 1869

Parameters of Support Vector Machines Model Optimized Method Based on Genetic Algorithm
Y.Z. Xie, Z.G. Wang and X.W. Dai 1873

Robust Exponential Stability of Stochastic Discrete-Time BAM Neural Networks with Markovian Jumping Parameters and Delays
L.D. Guo, J. Nie and Y.S. Zhang 1877

A Correlation Coefficient Estimation Algorithm Based on Subspace Decomposition
N. Wu, W.J. Si and S.H. Jiao 1883

A Multi-Objective Coordinative Optimization Model and its Cultural Immune Algorithm
C.G. Chang, W. Li, K. Yin and M.H. Qi 1887

The Implement of Parcel Sea Map Automatic Mapping Algorithm
D.R. Song, K. Cao and Y. Hao 1891

A New Network Traffic Classification Method Based on Optimized Hadamard Matrix and ECOC-SVM
H.Z. Wang and L.H. Yan 1895

A Novel Blind Watermark Extraction Algorithm Based on Nonsubsampled Contourlet Transform
L. Feng, X.F. Shi, H.Y. Chen, Y.H. Li and Y.L. Zhang 1901

An Improved Algorithm for Multi-Tag Anti-Collision in RFID System
Y.R. Zhao and W.L. Miao 1905

Numerical Simulations of Two Four-Petal Gaussian Beams Propagating in Strongly Nonlocal Media
Z.F. Yang 1909

An Approach for Sentiment Tendency Analysis on Comment Text
M. Li, M.D. Chen and X.B. Li 1913

Extending the α-Algorithm to Mine Repetitive Task Based on Complex Structure
H. Li, Y. Wei, X.H. Ye, S.W. Yao and J. Yang 1918

Process Mining: Overview and Comparative Analysis of the Mining Algorithms
H. Li, Y. Wei, L. Liu, S.W. Yao and J. Yang 1924

A P2P Resource Management Model Based on Cloud Computing
Y. Lu and G.F. Liu 1930

Architecture Research and Design of Cloud Computing Service Based on REST
K. Huang 1934

High Precision Data Processing Method Based on the Complex-Step Differentiation
F.L. Tan, Y.K. Guo, Y.M. Nie and F. Sun 1938

Routing Algorithm with Energy-Efficient and High Quality of Clusters in Wireless Sensor Network
Y.H. Yi and R.L. Wang 1942

DSP Memory Allocation Strategy Based on Greedy Algorithm
Y.H. Fan, X.F. Ma, J.S. Jiang, X.M. Xu, Q.Y. Hao and P. Zhang 1946

Research on an Embedded Ultra-Low-Bit-Rate Speech Coding Algorithm
Y. Li, Y.H. Fan, F. Yuan and X.M. Xu 1951

Research on Materialized Views under Disk-Space Constraint in Data Warehouse
L. Ma 1955

Review of Otsu Segmentation Algorithm
Y.X. Dong 1959

Non-Linear Least Squares Large Misalignment Estimation in Transfer Alignment
Y. Lu and X.H. Cheng 1962

Singularly Perturbed Systems with Diffusion and Time Delay
C.Y. Wang, Q. Dou and X.W. Li 1969

An Algorithm of DOA Estimation in Linear Canonical Transform Domain
H. Zhao, Y.H. Zhang and H.H. Li 1973

Computerized Simulation of Board-Level EMC in High-Speed PCB
X.Z. Wu, C. Zhang, S.F. Yang and L.Q. Zhao 1977

On Application of Texture Mapping Technology in Simulation
W. Zhang, C.H. Zhang and Y. Zhang 1981

The Discussion on the Improved Association Rules Algorithm in Data Mining
T. Wen, L. Sun and L. Zhu 1985

An Information Classification Optimization Model Based on Improved Ant Colony Algorithm
C.M. Hao 1989

Simulation Analysis of a Statistical Model for Herd Mentality Trend
S.Y. Pan 1993

Virtual Simulation of Aerobics Movement Based on Vision
X.H. Wang 1997

The Research of Key Data Classification Optimal Mining Methods for Massive Data
Y.Y. Li and Y.Z. Wang 2001

Group Customer Special Line Correction Algorithm Design and Application Based on PTN Technology
H.J. Zhu and D.F. Li 2004

Position Mobil Information Encryption Algorithm Based on Key Attributes of Reduced Rank Agent under Cloud Storage
H.L. Guo and H.L. Yu 2008

Network Intrusion Detection Model Based on Genetic Algorithm Optimizing Parameters of Support Vector Machine
C. Liu 2012

A New Method of Face Modeling with Construction of Local Texture Model
J.B. Shan, W.W. Jiang and S.L. Mu 2016

Simulation of Data Mining System Design in Database
R.Y. Zheng 2020

Analysis on Digital Signal Processing and Algorithm Based on Coherent Light
Y. Xing, L. Zhang, Z.Y. Cheng and K. Gu 2024

A New Improved Attribute Weight Algorithm Based on Rough Sets Theory for One Command Information System
S.M. Yang, Y.M. Yan, K. Wang and Z.Y. Xie 2029

Research on Leaning and Evolutionary Algorithm of Agent for Task Oriented
G.F. Xu and Y.W. Cai 2033

Research on Modeling of Brain Function Network in Major Depressive Disorder
L.M. Niu, H. Guo and J.J. Chen 2037

A Classification Algorithm of Moving Military Vehicle
Y.F. Ma and F. Chen 2043

Analysis of Fuzzy Clustering for the Adoption in Data Mining
Y.J. Wang 2047

Joint Spectrum and Power Allocation for Femtocell Based on Graph and Game Theory
Y. Wang and Q. Zhu 2051

The Research and Application of Data Glove in Virtual Interaction System
Y.X. Xu and X. Zhu 2057

Brief Report of Implementation of T9 Input with Python and Evaluation
Y.J. Wang 2062

Simulation Analysis of Mind Sports Games Based on Artificial Intelligence
G.W. Cui and X.Q. Li 2065

Genetic Algorithm Design on Scalable Data Mining of Cultural Industry
H.W. Xue 2070

Simulation Study of Waveform Variation of Fixed Assets Based on Logical Database Structure
S.P. Liu 2075

The Research of Data Mining Based on Neural Networks
Q. Guo and J. Niu 2080

Towards the Simulation of Evolutionary Programming
X.W. Li, L. Zhou and L.H. Yuan 2084

Based on Canny Operator with Regional Growth Combined Research on Accurate Image Segmentation Algorithm
J.Q. Miao 2088

Studying Sensor Networks and Multicast Algorithms with TACKY
C.C. Xu 2093

The Analysis and Realization of Interpreter Language in Nuclear Industry
Z. Zhang, H.B. He and H.L. Lu 2097

Time Prediction Based on Process Mining Taking Concept Drift into Consideration
F.F. Huang, L.Q. Zhang and Z. Li 2101

SBN Constructing Algorithm Based on Extended MEBN
S. Ge and X.Z. Xia 2106

A Mobile-Terminal-Oriented and Mobile-Cloud-Computing-Based Localized Scheduling Algorithm
R.X. Liu, Y.H. Zhang and Y. Tang 2111

Research of the Ubiquitous English Learning Based on Cloud Computing
S. Han and X.D. Zhang 2115

Simulation of Neural Network Recognizing Isolated Words under MATLAB Environment
F. Zhao 2119

The MapReduce Parallel Study of KNN Algorithm
C.Y. Wang and X.F. Zhou 2123

Software Structural Stability Evaluation Method Based on Motifs
C. Shan, L. Huang, C.Z. Hu, X.L. Zhao and J.S. Ma 2128

Locating Method for Character 2D Barcode
Z. Liu, S.C. Yin, S.C. Ye and H.R. Zheng 2135

Research on Motion Model of "Wind-Blowing & Trees-Swinging" and "Leaves-Falling & Branches-Broken" Based on Fractal Theory
H.Q. Liu, J. Wang and L.P. Feng 2139

Algorithm of Representing and Preparing for Resources in EEM
Q. Yu, T. Li, X. Zhang, Y. Lin, Y. Yu and N. Zhao 2144

Research of Computer Forensics Based on Benford's Law
M.J. Shan 2148

Using Zipf Distribution to Predict Popularity Data for Storage Systems
Y. Yang, W.Y. Li, M.N. Zhang, X.M. Ding and J. Dai 2152

A Method for Transforming the Online Handwritten Mathematical Formula into MathML
D.Q. Fu, W.Y. Zhang and S.T. Jhang 2156

Adaptive Bit Allocation Algorithm for OFDM System
W. Wei and W.D. An 2161

Stepped Cooling Control Model Based on Optimal Algorithm
Z.W. Yan, H.A. Bu, G.S. Ma and D.H. Zhang 2165

Cluster Center Initialization Parallel Algorithm for K-Means Algorithm
B. Yan, Y. Zhang, H.Y. Su and H. Zheng 2169

Study for Embedded Colony Algorithm Based on Morphological Technology
K.Y. Chen, X.Y. Zheng and H. Yu 2173

A Semantic Retrieval Method Based on Ontology
Q. Shen and M. Zhang 2179

Using PROSEPCT and SVM for the Estimation of Chlorophyll Concentration
J. Lv, F.L. Deng and Z.G. Yan 2184

Distributed Collaborative Filtering Recommendation Model Based on Expand-Vector
Y. Zhu, H.Y. Su, C.Q. Wang, B. Yan and H. Zheng 2188

Improved Ant Colony Algorithm Based on PSO and its Application on Cloud Computing Resource Scheduling
H. Yang 2192

Study on Traveling Salesman Problem Based on the Improved Chaos Ant Colony Algorithm
H. Yang 2196

An Improved Scheduling Algorithm for Cloud Storage
P. Wang 2200

A New Spatial Correlation Model Based on the Distributed RC-$_{\prod}$ Model
X.X. Liu, J.B. Shao and L.L. Zhao 2204

Study on Modeling of the Minimum Lethal Dose while Rescue Poisoning
C.X. Zhao, Y. Jiang, H. Yang and M.T. Cui 2208

Maneuvering Target Tracking Algorithm Based on Particle PHD Filtering
S. Gao, C.B. Chen and Q. Gong 2212

Applying Grey System Theory in an Ideological and Political Education Course
M. Zhang 2216

Ideological and Political Education Linear Regression Theory
M. Zhang 2220

An Improved Genetic Algorithm in Vehicle Dispactcher
S.H. Zhu and P. Tang 2223

Research on Robustness of Typically Opportunistic Network Routing Algorithm under Flooding Attack
G. Yu, D.F. Yuan, Y. Cui, Y.D. Wang and P. Zong 2227

A Localization Algorithm Research to Eliminate the Indoor NLOS Error
J.Z. Dong, Y.W. Wang, F. Wei and J. Yu 2232

Communication Network Alarm Correlation Based on the Confidence Fusion Algorithm
H.S. Gao and Y.M. Li 2237

A Purchase Prediction Based on Collaborative Filtering Algorithm
Z. Fu and L.F. Zhou 2241

K-Means Clustering Algorithm Method Based on Shuffled Frog Leaping Algorithm
Z. Tang and K. Luo 2245

A Modified Regularized Super-Resolution Reconstruction Algorithm
Q. Xie and W.Y. Chen 2250

Simulation of Whole Movement Process of Muzhuping Landslide with DDA and Prediction of Surge
Z.H. Dong, X.L. Ding, A.Q. Wu and B. Lu 2254

State-Space Model and Simulation for Dynamic Stall
W.D. Lei, G.C. Hu and Q. Liu 2258

CFD Simulation of Gas Distributor with Two Chambers
D.F. Zhao and F.G. Liu 2264

Ratio Based Weapon System of Systems Capability Gaps Assessment Method Research
X.X. Zhang, K.W. Yang, B. Zhang and J. Jiang 2268

Study on an Improved Median Filtering Algorithm
H. Zhang, M. Gao and H.L. Ren 2273

The Application of Cross-Correlation Algorithm in CSAMT Received Data Processing
Z.P. Zhou, Y. Zhu and T.H. Wang 2278

Assignment Performance at Beijing South Railway Station Based on Anylogic Simulation
Y.J. Liang and Z.Z. Yuan 2283

Study of Storm Surge Numerical Simulation in the Bohai Sea
Y.Q. Zhang, Q.L. Leng, Z.J. Hu, Z.C. Zhu, W.J. Zhang and S.H. Bian 2288

A Method of Domain Compound Concept Extraction Based on Multilevel Filter
B. Wu and L.B. Ouyang 2292

Design and Realization Based on Cloud Stack Hybrid Cloud Computing Platform
P. Cheng and H. Qu 2297

A Particle Swarm Optimization Algorithm Based on Simulated Annealing
Z.C. Yan and Y.S. Luo 2301

The Gray Relation Analysis of Non-Coal Mine Accidents Causation
X.Y. Meng, R.H. Chen and S.B. Wang 2306

Research on Algorithm of Video Segmentation Based on Self-Adaptive Single Gaussian Model
Y. Zhu, D.H. Wang and J.L. Liu 2310

Research on the Evaluation Method of OSHMS Performance Based on Fuzzy Theory
H.M. Zhou and D.T. Hu 2314

Parallel Sets Based on the Improved ACLEARCR Algorithm
H.K. Zhang, N.W. Sun, C. Zhang, T.T. Jiang and C.H. Dai 2318

Evaluation of Ground Thermal Infrared Camouflage Using Pure Technical and Pure Scale Dynamic DEA Model
L. Li, X.L. Lv, B.Z. Li, X.P. Li and H.X. Wang 2323

2D Numerical Simulation of Termal Discharge in Coastal Area
T. Xu 2328

Study on Settlement Process of Dredger under Current Force
T. Xu, Z. Xiao and L.C. Sun 2332

The Effect of Enterprise Business Process Reengineering Fuzzy Comprehensive Evaluation
S. Ling and C.Y. Ye 2336

A New Highway Safety Model Based on Cellular Automata
L.X. Li 2340

A Model for Seat Allocation of Railway Passenger Transport Based on OD's Priority
Y.T. Zhu, F.Z. Wang, X.H. Shan and X.Y. Lv 2344

IBC-Based Authentication Protocols and a Method of Data Sharing for Cloud Systems
K.K. Chen, C.L. Cao, J.Y. Liu and R. Zhang 2349

J-Integral Computation in Mixed Mode I and II
Y.M. Cai, F.Y. Zhang and Y.J. Xie 2356

A Kind of MSD Performance Compensation Method Based on the Strategy of Sliding
D.X. Zhu, G. Fu and Q. He 2360

Research on Phase Locked Loop Software Parallel Processing Methods
R.L. Li, G. Fu, Y.J. Wu and L.P. Wang 2364

An Algorithm to Control Watermarking Capacity Using PSNR
Y. Xing and D.S. Wang 2368

Simulation of Dynamic Compaction on Soft Soil Foundation
Y.L. Pang and D.M. Dai 2373

Look the Partial Equilibrium with the Global Optimum from the Problem of the Shortest Circuit for Three Villages
X.W. Jiang, Y. Hu, Y.T. Yang and T. Luan 2377

Adaptive Discriminant Linear Local Tangent Space Alignment Algorithm on Face Recognition
Y.X. Lv, Y.N. Deng, Y. Shi, Q. Li and W. Peng 2381

Research on the Traffic Rules of the Freeway
Y.X. Jiang 2385

A Collision Detection Algorithm Using AABB and Octree Space Division
H.Y. Wang and S.G. Liu 2389

A Visual Hiding Algorithm Based on Human Visual System
R. Dong and D.S. Wang 2393

Augmented Lagrangian Method for Nonlinear Programming with many Complex Constraints
X.W. Jiang, Y.T. Yang and Y.L. Lu 2398

Consensus Equilibrium Point Analysis for Heterogeneous Multi-Agent System in Undirected Graph
Y.J. Sun, G.L. Zhang and J. Zeng 2402

A Projected Conjugate Gradient Method for Box-Constrained Optimization
T.F. Li, Z.Y. Liu and Z.B. Du 2406

Decomposition of New Construction Land Quota in Rural Land Based on AHP
X.W. Cai, H.Y. Wang, Y. Sun and C.H. Gao 2410

Design and Implementation of General High-Speed Data Storage System
G. Fu, W.J. Geng and R.L. Li 2414

Research on Software Algorithm Capture of Spread Spectrum TT&C Signals
R.L. Li, G. Fu and G.Z. Wu 2418

Improved Genetic Algorithm in Vehicle Management
S.H. Zhu and T. Kuang 2422

Detecting Epistasis by LASSO-Penalized-Model Search Algorithm in Human Genome-Wide Association Studies
Z.H. Zhou, G.X. Liu, L.T. Su, L. Han and L. Yan 2426

A Fuzzy Clustering Algorithm Based on Parameter Optimization in Large Transaction Database
W. Su, X. Zhang and J.J. Xu 2431

A Hybrid Approach for Critical Technology Identification
C.Y. Li, J. Jiang and M.J. Li 2438

Coupling Sentiment Dictionary and SVM Classification for Text Orientation Analysis
M.Z. Gao, F.F. Li, Z.Y. Ding and W.D. Xiao 2444

Research on the Optimization of the Storage Strategy of HDFS
H. Cao 2450

Research on Packet Encryption Algorithm in the Cloud Storage
H. Cao 2454

ZFDV: Zoom Financial Data Visualization in the Era of Big Data
T.T. Jiang, Q.G. Wang, H.K. Zhang, W.D. Xiao, C. Zhang and B. Ge 2457

A New Analysis of the Iterative Threshold Algorithm for RPCA by Primal-Dual Method
R.Y. Fan, H.X. Wang and H. Zhang 2462

Robot Path Planning Based on Artificial Fish Swarm Algorithm under a Known Environment
J. Wang and L.J. Wu 2467

A Study of the Keep-Right-Except-to-Pass Traffic Rule on Cellular Automata
W.B. Cao 2470

Probabilistic Model Checking by Model Equivalent Reduction and Abstraction
Z.L. Bai, L.Y. Xu and Z.S. Yu 2474

Computing Volumes Surrounded by a Quadric Surface and a Plane with MATLAB
Q.L. Yin 2480

A New Defogging Algorithm Based on Atmospheric Degradation Physical Model
X.G. Li 2484

The Evaluation of Teaching Quality Based on Fuzzy Method
J. Zhu, J.Y. Tian, J.H. Hao and S.Y. Zhang 2488

Identical Distributed Pairwise NQD Random Variables Sequences with a Novel Mutation Operator
J. Cao, G. Li and C.R. Ma 2491

Improving Performance of Wireless-Optical Broadband Access Network by Interpolation Algorithm of Zadoff-Chu Sequence
J. Cao, C.R. Ma and X.J. Hu 2495

Image Fusion Algorithm by Improved Chaos Immune Genetic Algorithm in Multi-Wavelet Transform Domain
J. Cao, T.F. Li and Y.P. Gao 2499

Interpolation Algorithm Application Using Neural Networks for Flywheel Energy Storage System
S.S. Wan, J. Cao, Q.S. Zhu and C. Yan 2503

The Application of Correlation Dimension in the Multi-Objective Comprehensive Evaluation of the Large Complex Equipment Procurement Scheme
Y.X. Yang, F.J. Wei and F. Wang 2507

Modeling and Simulation of Vehicle Traffic Detection System Based on Ground Sense Coil
J.W. Ju, J.Y. Liu, W. Yang and N. Liu 2511

Efficient Simulation for Dynamic Systems with Discontinuities
Q. Yuan 2515

Optimization Model and Algorithm for Responsive Closed-Loop Supply Chain Logistics Network with Direct Shipment under E-Commerce
J. Liu, Q. Li and H.W. Wu 2519

Tabu Search for Bus Crew Scheduling with Feasible Sets of Shifts
J. Wang, J.H. Ma, W. Guan and H.T. Gu 2523

Modified Harmony Search Algorithm for Unconstrained Numerical Optimization Problems
H.G. Xia and Q.Z. Wang 2528

A Modified Harmony Search Algorithm for Numerical Optimization Problems
H.G. Xia and Q.Z. Wang 2532

Modified Differential Evolution Algorithm for Numerical Optimization Problems
H.G. Xia and Q.Z. Wang 2536

People Counting Based on the Moving Feature of the Mass
P.Z. Qiao, T. Li, T. Xiang and X.Z. Zhang 2540

A Cloud Storage Encryption Scheme Based on Separated Key and Encryption Policy
P. Wang, F.Z. Zhang and C.L. Han 2543

Method Based on the Minimum Deviation for Multi-Attribute Decision-Making and its Application
H.A. Zhou 2547

Orthogonal Semi-Supervised Marginal Fisher Analysis
X.Z. Liang and Y.E. Lin 2551

Simulation Research on GM Navigation Based on AFSA
Z.L. Zhu, G.L. Yang, J. Li, S.J. Yang and Y.Y. Liu 2555

Currency Crisis Prediction Using Wavelet-Based Support Vector Machine
Q.L. Zhang 2560

An Improved Speech Enhancement Algorithm Based on Wiener-Filtering
Y.H. Liu, D.M. Zhou and J. Di 2565

Research of License Plate Recognition under Complex Environment
F. Gao, Z.J. Dai, K. Zhou and Y.P. Dai 2569

Hidden Markov Modeling for Nakagami Fading Channel
Y.H. Yang, L.F. Wang and Y.P. Sun 2576

Application of Multipurpose Decision Making Problem with AHP and Rectilinear Norm in Old Town Renewal Proposals
B.J. Zhang 2580

Application with AHP in Assessment of House Plans
B.J. Zhang 2588

Algebraic Immunity, Correlation Immunity and other Cryptographic Properties of Quadratic Rotation Symmetric Boolean Functions
J.L. Huang, Z. Wang and M.R. He 2593

Relations among E-Derivative, Derivative, Algebraic Degree, Correlation Immunity and Annihilators for H Boolean Functions
J.L. Huang, Z. Wang and J. Li 2599

Moving Vehicle Detection Scheme Using Edge Information and Background Subtraction in YCbCr Color Space
W.X. Yu and J. Su 2605

A Hybrid 2-Population Genetic Algorithm for the Job Shop Scheduling Problem
Z. Xu, R. Wang and Z.M. Wang 2609

Robust Principal Component Analysis Algorithm Based on Nonparametric Correlation Coefficient Matrix
N. Zhao and H.Y. Shao 2613

Design Modeling and Simulation by Interpolation Algorithm of Zadoff-Chu Sequence
S.S. Wan, Q.S. Zhu and J. Cao 2617

Particle Swarm Optimization by Improved Chaos Immune Genetic Algorithm
S.S. Wan, J. Cao and Q.S. Zhu 2621

The Research of Financial Risk Warning Model about Real Estate Enterprises in China
X.R. Tian, H.D. Jiang and J.L. Liu 2625

Prediction Model of Aerosol Fire Extinguishing Agent Performance Based on Combination of Genetic Algorithm and Back-Propagation Neural Network
Z.J. Chen, C.G. Zhu and Z.H. Zhang 2629

$F_P+vF_P+v^2F_P$
L. Chen and M.J. Shi 2634

Dynamic Network Model Analysis Based on Communication Network
N.Q. Yuan, T. Jiang, S. Bai, H. Sun and J.M. Zhao 2639

The New Class of Laplacian Integral Graphs
S.F. Lu and J.Y. Zou 2643

An Efficient Methodology for Estimating Interconnect Crosstalk Noise in Deep-Submicron Technologies
X.X. Liu, J.B. Shao and L.L. Zhao 2647

Feature-Based Real-Time Visual SLAM Using Kinect
Y. Song and B. He 2651

Research Progress in Topological Relations of Objects with Holes
S. Di, J.M. Zhang, Y.F. Shi and L.L. Zhang 2655

Complexity Research on Second Class Orthogonal Weight Function Neural Networks
D.Y. Zhang and R. Zhao 2659

Research of the First Kind of Padé Weight Function Neural Networks
D.Y. Zhang and Y. Xu 2663

Time Complexity Research on the Second Type Neural Networks of Padé Weight Functions
D.Y. Zhang and L. Yang 2667

Research on Safety Comprehensive Assessment Method for Air Traffic Control Based on RBF Neural Network
X.S. Gan and H.P. Li 2671

On the Application of Ant Colony Neural Network for the Highway Traffic Safety Facilities System
G.L. Jia, R.G. Ma and Y.J. Deng 2675

Numerical Simulation of Cook-Off for Passive RDX
C. Chen, W.B. Li and J. Liu 2679

Traffic Flow Prediction with few Data Using Fuzzy Neural Network Method
W. Zhou and X.X. Wang 2684

The Evaluation to Influence Factors of Concrete Durability Based on Grey Correlation Degree Method
X.P. Su and H.Y. Sun 2688

Camshift Algorithm Based on Multi-Features, and its Further Improvement Study
J.H. Lin and G. Fu 2693

Study of Numerical Simulation of RF Wave in Magnetized Plasma
J.F. Jiang, Z.H. Jiang, X.F. Sun and W.X. Guo 2697

Research on Workpiece Deformation in Electromagnetic Forming Process with Finite Element Method
C. Peng, L. Qiu, K.S. Gong and D.J. Wang 2702

Research on Learning Algorithm of RBF Neural Network Based on Extended Kalman Filter
X.S. Gan and H.L. Gao 2705

Interpolation Algorithm Application of Zadoff-Chu Sequence Using Neural Networks
J. Cao, Y.B. Li and C. Yan 2709

Comparison on Turnovers of Agricultural Products Futures Based on Hilbert-Huang Transform
Q.B. Han and H.L. Shi 2713

From Epanechnikov Mixture Model to Rule-Centered Fuzzy Model and its Application to Stock Index Prediction
Q.L. Zhang 2719

A Multifactor Grey Forecasting Model of Agriculture Output Value
W.Z. Chen and L.J. Liang 2723

Research on Software Demodulation of PCM/FM Algorithm Based on MSD
G. Fu, Y.J. Wu, R.L. Li and L.P. Wang 2727

Mixed Features Based Improved Human Action Recognition Algorithm
H.L. Jia and K. Cao 2731

Knowledge-Based Fuzzy Diagnostic Model
H.W. Lv, X.K. Li and K. Wang 2735

Chapter 6: Advanced Technologies in Mechanical Engineering, Mechatronics, Automation, Measuremant, Control and Manufacturing Technology

Design and Simulation for New Type Pulley Straightening Machine Based on Pro/E
J.H. Geng, B. Yu and B. Fan 2741

Based on the Modeling and Simulation Analysis of the Spray Pump of Soildworks
D.D. Jiang, Z.B. Zhou, J. Xu, L. Chen and M. Li 2745

Study on the Statics Analysis of Promoting the Drilling Efficiency of PDC Anchor Bit
Y. Li, Y.F. Song and Y.L. Mao 2749

Impact of Tooth Shape Parameters on Strength Safety Coefficient of Herringbone Planetary Train
Z.B. Zhu, C.Q. Shu, Y.L. Xu, C. Li and M. Yin 2753

Design of Monitoring System for Hydraulic Support Based on LabVIEW
S.S. Tang and C.K. Wei 2758

Research of Laser Induced Fluorescence Detection Techniques Based on Microfluidic Devices
Y.Q. Cheng, C.L. Guo, B. Zhao and L. Yang 2761

Detecting Ultra Low Carbon and Sulfur Contents in Steel by Using Infrared Absorption Method
M.R. Bayati and P.Y. Wei 2764

Research Progress of Detection Method of Sulfur in Iron-Base Alloys
M.R. Bayati and P.Y. Wei 2768

Experimental Study on Active Vibration Control of Flexible Manipulator Based on Improved PPF Algorithm
F. Du and T.B. Ma 2774

The Wind and Light Power Supply System Controller in the Mobile Base Stations
H. Ma 2778

Study on Dynamic Mechanism of LOGINK Service Innovation Based on System Dynamics
L.L. Li, S.W. Ji and L.S. Wang 2782

Numerical Simulation of the Kinetic Energy Projectile Deflected by Targets Moving along Transverse Direction
J. Chen and X.J. Ye 2787

City Sludge's Differential Scanning Calorimetry Analysis
L. Yang and S.H. Lin 2791

Research on the Regionalism Air-Conditioning System Design of Car and Saving Energy
L. Ouyang and D. Li 2796

Design of the Hydraulic System for Carrying Manipulator with 6-DOF
M. Wang, C.D. Wang, H. Zheng and G.F. Fan 2802

Simulation and Study of SPWM Variable-Frequency Drives of Asynchronous Motors Based on Aerostatic Guide Way
W. Long, Y. Liu, X.L. Zhang and T.Y. Wang 2807

Implementing Lean Techniques on the Shop Floor Improvement of a Delivery Company
J. Shay and P.I. Shieh 2811

Research on Direct Torque Control Adaptive Fuzzy Neural Network Controller of Permanent Magnet Synchronous Motor
C.F. Lu and H.B. Yu 2815

The Series and Parallel Energy Storage System Based on Super Capacitors
K. Zhao, Y.B. Zhang and B. Yu 2820

Nonsmooth Bifurcations in a Cracked Rotor-Active Magnetic Bearings System
F.H. Yang and H.Z. Tong 2825

Modeling and Analysis of Arresting Property of EMAS
H.H. Zhao and H.B. Yu 2829

Comparison Research on Aerodynamic Drags and Pressure Coefficients of Reference Car Models in Automotive Wind Tunnel
Y.C. Zhang, W. Ding, Z. Zhang and J. Li 2834

Performance Analysis and Simulation Study of Boiler-Turbine Coordinated Control System
Y.Y. Jiang and D.F. Wang 2839

Exploration on the Dual Spool Design of Rotary Hydraulic Valve
L.J. Qiu and S.Y. Xu 2845

Computing Method of Auto-Rotated Precision Index of Gun Barrel Based on Exterior Ballistic Computation
Y.D. Yang, J.S. Ma and C.Z. Jia 2849

Parameter Matching and Simulation Analysis on Power System of Plug-In Hybrid Vehicles
D. Ji, H.F. Zhang and J. Yang 2854

Buckling Stability Analysis of Parallel Micro-Spring
J. Zhang, L. Sui, X.H. Guo and G.H. Liu 2859

Passivity-Based Control of Motor for Reaction Wheel
R.L. Yu and J. Jin 2865

The Study of Mine Explosion-Proof Enclosure Design and Optimization
Q.L. Zhang and S.J. Yang 2869

Research for Guide Groove Configuration of Rotary Valve
S.Y. Xu 2874

A Study of Influence of Shape Technique on Radar-Scattering Characteristic for Tank Turret
Y. Ma, W.D. Xu, F.M. Shi, J. Liu, F. Lu and L.Y. Zhu 2878

Feasibility Investigation for Visible-Laser Compatible Camouflage Thin Film
L.Y. Zhu, W.D. Xu, A. Wan, Z.Y. Zeng and Y. Ma 2882

PWM Control for Actively Clamped Resonant DC-Link Inverter on Soft-Switching
Y. She 2886

Design Improvement on Shipping Container Spraying Production Line
S.O. Okorie and J. Shi 2890

Overview of the Control Methods for LTCC Substrate Shrinkage
X.D. Liu, S.H. Wang, Z.X. Hou, D. Zhou and L.Q. Yang 2895

Research on Fault Diagnosis Method for Crankshaft of Drilling Pump Based on Operational Deflection Analysis
F.F. Bie, J.F. Pei and F.X. Lv 2899

Hydraulic Vibration Exciter and Hydraulic Circuit Design Research
J. Yang 2904

Path Planning for Circular Cutter Envelop Milling of Steam Turbine Blade
J.J. Wang, K. Wang and Q. Wu 2908

Improving Design of Cup Conveying Part for Sealing Machine Based on PLC
L.A. Pan, Q.L. Du and Y.L. Wu 2913

Research on the Optimal Design and Gear Modification of Gearbox of a Wind Turbine Based on the Virtual Prototype
H.B. He, H.Y. Li, J. Yang, G.C. Lu and T. Gu 2917

Thermal Structure Coupling Analysis of Lathe Built-In Electric Spindle under Intermittent Load
K. Wang, J.H. Liu, G.K. Wu and X.W. Sun 2922

Analysis of Impact of Driving Amplitude on Resonance Frequency of Silicon Microgyroscope
S.D. Jiang, Y. Su, Q. Shi and A.P. Qiu 2926

Research on Credit Evaluation and Verification Model in Equipment Manufacture Industry
L.F. Zhao and S.H. Zhou 2931

The Improvement for the Structure of the Coil Transporters and its FEA
Q. Wang, Y. Sun, Z. Li, X.Q. Peng and B. Han 2935

The Influence of Diamond Graver's Edge Radius in Diffraction Grating Scoring Process
P. Sun, H.W. Wang, X.Y. Zhang, L.M. Qiao and X.L. Wei 2939

Stress Characterization and Mechanical Analysis for Supporting Leg of SiGe/Si MQWs Based Bolometer
B. Jiang, T. Dong, Y. He and Y. Su 2943

Analysis of Aircraft Hydraulic System Failures
W.G. Zhang and G.M. Lin 2947

Design and Realization of Remote Control UAV's Flight Controller
Y. Tian, H.D. Deng and H.Y. Zhuang 2951

Study of AT Based on the Lever Method
J.J. Li and J.H. Li 2955

Design and Analysis of Hydraulic Piston Structure Exciter
S.J. Wang and K.L. Yu 2959

Design of Underground Gas Concentration and Humidity Monitoring System Based on RS-485
Y.H. Long 2962

Adaptive Controller for ROV Based on Hybrid Theory
Y.H. Xie 2965

Data Storm Monitoring System of Large Power Industrial Control Network under Non Uniform Format
L. Liao, Y.H. Huang and C.J. Zhao 2970

Design and Calculation of a New Type of Elastic Gear Coupling and Finite Element Analysis
F. Chen, Z.F. Li and Y.X. Liu 2975

Study of Sub-Synchronous Control Interaction (SSCI) Based on the Test Signal Method
B.F. Gao, J. Liu and S.Q. Zhao 2980

Estimation of a State Vector of an Inertial Unit
H.P. Zhang, P. Pei, R. Ceschi and O. Rabreau 2985

Study of a Predictive Compensator for Internet-Based Remote Vehicle Steering Control
M.G. Zhong and H.C. Hong 2990

Research on Auto-Test System of Telescope Laser Indicator
N. Zhou, Y.H. Li and X.Y. Li 2995

The Development of Underground Personnel Data Terminal Based on RSSI Location
H.Y. Li and C.Z. Chen 2999

The Design of Embedded Video Monitoring System Based on DSP Processor
W.B. Hu 3003

A Calibration Method of Binocular Stereo Vision System Based on Halcon
Z.X. Zhang and Z.D. Zhu 3007

The Brief Introduction of Several Common Subway Shock Absorber Fasteners in China
H.P. Luo, D.J. Cai, M.L. Liu and P. Wang 3011

Design of the Improved Accompanying Temperature Logger
J. Guo, S.Y. Liang and Z.T. Yin 3015

Coiling Tension Control System of PID Simulation
Z.C. Wang, Y. Ding, H.Y. Zhao and X.D. Hu 3019

Structure Principle and Measurement Index of New Energy Reclaiming Suspension
J. Bai, Y.Z. Guo and M. Peng 3025

Method Research on Bending Fatigue Test of Vehicle Steering Wheel
X.J. Xu and L. Tian 3029

The Method of the Abnormal Sound Detection for Final Drive Based on DSP Technology
X.J. Xu and Z.G. Fang 3033

The Multi-Body Dynamics Contact Simulation on Transmission Gears
X.H. Deng 3037

Analog Circuit Parameters Measurement System Based on Multiplier
Y.X. Wang and M. Hu 3041

Numerical Simulation of Skid Steer Loader Steering Characteristic
F. Ren, X.H. Liu, J.S. Chen, P. Zeng, X.F. Jia and Q.M. Wang 3045

A Improvement of the Keep-Right-Except-to-Pass Rule in the Model of Modified CA (Cellular Automata)
Y. Ma 3050

Design and Implementation of Remote Control System Based on Embedded Mobile Network
J.X. Wei 3054

Vibration Analysis of Cable Suspended Parallel Mechanisms with Dynamic Base Platforms
Y.P. Hu and L.M. Tao 3058

The Design of Monitoring System in Large Hydraulic Press Aiming at the Precise Closed-Loop Control
H. Du, B. Huang, L. Wang and S.M. Chen 3062

Based on the Geostress to Research Slope Stability in the Deep Open Pit
Q.W. Li, L. Qiao and L. Chen 3070

Improvements on Structural Static Pushover Analysis Method in High-Rise Building Structure
M. Yu, Z.H. Dai and G.J. Hu 3075

Dynamics Analysis of Manipulator in the Hot Line
D.D. Zhang 3079

Design and Implementation of Driving Mechanism on Software Aerospace Measurement and Control System
G. Fu, M.X. Kou and R.L. Li 3084

Research on Workshop Layout Based on SLP and Witness
Q. Cheng, T.M. Guan, L. Sun and F.B. Jing 3088

Study on the Voltage Measurement in a Battery Manage System Based on LTC6802
Y.W. Zhu and B. Shi 3092

Research on Multistage Horizontal Well Fracturing in the East of Sulige Gas Field
Y.F. Xue, D. Li and Z.Y. Zhu 3096

Numerical Analysis of Heat and Mass Transfer Performance of the Packed-Type Parallel Flow Dehumidifier
R.H. Zhang, Z.Y. Wang and R.P. Niu 3100

A Novel Vertical Lift Machine and its Precise Pose Control
X.B. Liu, X.F. Wei, X.D. Yuan and W. Ni 3105

Investigation on Flat Wheel In-Suit Measuring System and Errors Compensation for Wheel Radius under Aspheric Grinding Process
F.M. Nie, Z.G. Li and Q.T. Wu 3110

An Intelligent Fault Monitoring System for Hydraulic Excavator
L. Ni, X.S. Chen, A.L. Wang and S.K. Cao 3114

Modeling and Simulation of Feed Drive System Vibrations Based on Dual Inertia System
L. Luo, W.M. Zhang and Y.L. Zhang 3117

Comparative Study of Moving Target Analysis System
M. Feng and H.C. Du 3122

The Injection Mold Design of Clamshell Phone Upper Cover
G.D. Liang and J.H. Liu 3127

Based on PMAC Control 4-DOF Manipulator
J.W. Fan, Y.J. Liu, L. Chen and C. Liu 3132

Development of a Rotary Drilling Mechanism for Impregnated Diamond Bits
Z.T. Li, Y.Z. Ma and K. Itakura 3136

Studies on Backward Median Current Waveform Control Research in Pulsed MIG Welding
Q. Zhu, J.X. Xue, X.L. Zhang, C.W. Dong, Z.S. Chen, Z.H. Li and P. Yao 3140

Soil Moisture Monitoring System Based on RS485 Bus
L. Wang 3145

The Finite Element Analysis of the Large-Diameter Composite Slurry Valve Gate
J. Wu, Z.M. Yang and D.Z. Wang 3149

Fit Degree Calculation of an Aircraft Part Manufacturing Process
X.F. Huang, F. Zhu and N. Wei 3153

Fuzzy Adaptive PID Controller Optimization Design in Temperature Control System
X.P. Li and L.Z. Chen 3157

Research on the Correction of Regeneration Opportunity of DPF Using GW4D20 Engine
S.J. Qiao and Y. Liu 3161

Dynamic Characteristics of Arch Steel Tower in Construction Stages
L. Yu, Y.Y. Che, S. Wang and G.H. Zhao 3165

Inhibition of Return Effect Reversed by Perceptual Load
X.J. Liu, Z.H. Fan and J.Z. Zhou 3169

Brushless DC Motor Speed Control System Based on Fuzzy PID Control
Y.H. Zhang and L.P. Song 3172

Research on Algorithm to Improve Performance of Multi-Wheel Steering Control System
S.S. Wan, J. Cao, Q.S. Zhu and C. Yan 3177

Research on Image Vectorization Based on Dual-Thumb Pneumatic Flexible Robot Hand
S.S. Wan, J. Cao, Q.S. Zhu and C. Yan 3181

Based on ANASYS with Finite Element Analysis and Calculation of Cracked Pipeline
X.M. Zhu and Y.P. Lv 3185

Simulation Study of Magnetic Memory Signal Correlation Effect of Dual Defects by ANSYS
X.W. Xi, S.K. Ren, Y.F. Zhang and Y. Huang 3189

Temperature Control Features and Simulation Research on High and Low Gimbals
Z.J. Xiao, X.X. Guo, H.B. Zhu, Z.G. Xu and Z.Y. An 3195

Prediction System Design on Noise Airworthiness Compliance
G.H. Yan, S.Q. Liu and W.Q. Song 3199

Separating the Time Field Signal of Rotor Unbalance Vibration Based on EMD Method
S.H. Zhang, X.W. Guo and Z.M. Zhang 3204

Application of Rapid Prototyping Technology in Product Design
D.T. Li, Z. Zhang, J.W. Deng, M.Y. Huang, X.F. Wan and H.J. Ni 3208

AHP Effectiveness Evaluation of Electronic Warfare Command and Control System under Complex Electromagnetic Environment
G.S. Wang and Z.F. Qi 3212

Design of Quadrotor's Control System Based on DSP
Q. Lv, P.P. Ni, G.S. Wang and F. Liu 3216

Fault Diagnosis of Rolling Bearing Based on MED and Morphological Filtering
S.K. Liu, G.J. Tang and B. Pang 3220

Transform a Mechanical Testing Machine into High-Temperature Disk Spring Stress Relaxation Test Equipment
X.Y. Zhou and Y.Z. Yu 3224

Vista of Silt Brick Cutting Machine Development Situation
Z. Zhou, Y. Lv, H.J. Ni and C.Q. Wu 3228

The Design of the Single-Phase Inverter Based on DSP (TMS320F2812)
Z.X. Zhou and J.E. Huang 3231

LDO of High Power Supply Rejection with Two-Stage Error Amplifiers and Buffer Compensation
Y.T. Chang, Y.D. Shiau, P.C. Wu, R.H. Xue and P.Y. Cheng 3236

The Research of Numerical Control Transformation Based on Turbo PMAC
H.C. Sun, L.N. Li and S.P. Deng 3240

Rotor Local Rubbing Fault Feature Analysis Based on Teager-Huang Transform
S.K. Liu, G.J. Tang and B. Pang 3244

Coupled FE-SPH Simulation of a High-Speed Grinding Process Using a Multiple-Grain Model
R.D. Shen, X.M. Wang and C.H. Yang 3248

Sensorless Control of Switched Reluctance Motors Based on Pulse Injection, Position Sectors Divided and Variable Thresholds
Z.F. Jia, D.A. Zhao and Y.Y. Zhao 3252

Research on the Static Cushioning Property of Folding Corrugated Cushions
Y.M. Qi and W.H. Gao 3258

Interesting Packaging Structure Design of Children's Biscuits
Y.M. Qi and W.H. Gao 3262

Study on Axis Calibration Method of the Coordinate Measurement System Based on Binocular Vision
Z.M. Zhang, S.H. Zhang and Y.N. Yu 3266

Research on Cantilever Used for Thermal Flow Meter as Switch
Z.L. Zhang, Y.Q. Wu and C.M. Liu 3270

The Design of Multichannel Marine Seismic Acquisition Unit Based on ADS1282
Z.L. Zhang, Y. Zhang and P. Chen 3274

Complicated Manufacturing System Dynamic Measure-Control and Intelligence Diagnosis
J. Ma, W.W. Li and P.T. Liu 3278

Communication Module Design of Offshore Drilling Platform Cleaning Robot
Y.X. Jiang, J.F. Liu, X.H. Zhang and Y.L. Zhao 3282

Design of Pneumatic Parachute-Packing Machine
Y.F. Wang, S.P. Deng, B. Chen and L.L. Zhang 3286

Development of G-Code Based on PMAC in CNC Machining Center
C.C. Cao, Q.H. Sun, S.P. Deng and Y. Zhou 3290

Research on Automatic Changing Film Mechanism of $PM_{2.5}$ Sampler
Y. Mei, S.P. Deng, K. Yang, W.F. Zhou and J.T. Wu 3294

Design of Shock-Absorbing System for Disaster Rescue Robot
L. Xie and Y.M. Qi 3298

Failure Analysis and Preventive Measures of Cooling Tower Fan Gearbox
J.P. Chen, Y.L. Wang, C.X. Zhao and X. Li 3302

Application of Viscous Pressure Forming in Aeronautics and Astronautics
J.G. Li, J.G. Zhang, J.P. Liu, R.F. Zhao, Y. Li, Y.C. Li, S.X. Yu and Z.J. Wang 3306

Methods of Metal Parts Unfolding
Y. Li, J.G. Zhang, J.G. Li and Y.C. Li 3310

Equipments of Pulsed Welding System and its Application
L.Y. Lou and Y. Gao 3314

Reviews on Automobile Abnormal Sound Fault Diagnosis
G.L. Tan, D.H. Miao, Y.M. Qi and S.P. Deng 3319

Research on Disassembling Equipment for Construction Machinery Hydraulic Cylinder
X.H. Zhang and J.X. Zhang 3323

Stiffness Modeling and Sensitivity Analysis for Worm Geared Transmission
L. Han and H.J. Qi 3328

Theoretical Surface Roughness Model in High Speed Face Milling
T. Zhang, G.H. Li and L. Han 3331

An Analysis of Electric Inertia Simulation Method on the Test Platform of Electric Bicycle Brake Force
Z.X. Yu and H.B. Yu 3335

A Simple Criterion for Robust Stabilization Design of Interval Time-Delay Systems
C.H. Lee and P.S. Liao 3340

Optimization of Operation Frequency in the Evaluation of TBCs Using Microwave Technique
Y.E. Yang and G.M. Zhang 3344

Damage Detection of the Honeycomb Sandwich Panel Based on Frequency Dactylogram
G.C. Li, Y.Q. Li and Y.L. He 3349

The Research of Fluid in the Cross Micro-Channel
J.Y. Li, W. Zhou, X. Zhang, Y.F. Jiang, L. Yang and S.X. Zhang 3354

Research to the Model Design of Real Platform Based on the Simulating Network
G.Q. Liu 3359

Fatigue Loads Prediction Based on a Hybrid Road Approach
Y.H. Mei and Q.S. Xie 3363

Assessing the Harmonic Emission Level Based on Partial Least-Squares Regression with Data Envelopment Analysis
X. Li, M.Y. Chen and Y.W. Zheng 3367

Software Design of Micromouse Dash Motion
H.M. Zhang, L.S. Peh and Y.H. Wang 3371

Double DSP Communication Based on CAN Bus Interface
H.D. Deng and Z. Yan 3375

Aerospace Test and Launch Process Dynamic Management System Based on the Network Diagram Method
Y. Wang, H. Wang and Y. Li 3379

Research to the Development of Network-Anticipated Controlled System Based on Arbitrary Bounded Packet Loss
G.Q. Liu 3382

Flatness Feed-Forward Control Model Based on Neural Networks
Z.W. Yan, H.A. Bu, D.H. Zhang and J. Sun 3386

The Design of Greenhouse Environment Monitoring System Based on ZigBee
G.S. Chen, Z.S. Wang and X. Shang 3390

The Design of Portable Granary Thermometer
G. Qin and D.Q. Cui 3394

Research and Design of Light Moisture Tester
Y.P. Tang 3399

Software System for Unmanned Surface Vehicle Using PCI8602
X. Shi, S.M. Wang, Z. Xu and Q.Y. He 3407

Research on Integrated Application of Multi-Display Technology in the Mobile Terminal
X.M. Mao and J.G. Liu 3411

Design of Remote Monitoring System of Temperature and Humidity Based on Internet of Things Technology
L. Wang 3415

The Design of Intelligent Home Furnishing System of Internet of Things
L. Wang 3419

Transmission Delay Monitoring Method in Intelligent Substation
X.H. Song, Z.Z. Guo and G.B. Li 3423

Study of Maximum Power Point Tracking Control Based on GRNN Neural Network
K. Liu, T.Z. Ji, X.Y. Li, X.F. He and M. Zhang 3427

Arrangement of Sensor Nodes for Wireless Sensor Network in Aquatic Products Breeding
B. Shi, S.K. Xu and J.M. Jiang 3433

A Platform of Lightning Protection Business Based on Tablet-PC
Y.H. Zhang, J.C. Zhou, X. Jiao, J. Zhou and Q.F. Zeng 3437

Prediction and Analysis of Safety Production Accident in Mining Based on the GM(1,1)
C.F. Jiang, K.P. Hou and H.F. Sun 3443

A Production Planning and Scheduling Process Study Based on Dynamic Information Feedback
Q. Yang and Y.H. Ni 3447

The Key Technology Research on Information Acquisition about Tropical Crop Production Environment
L.L. Wang, K. Lu, H.X. Luo and J.H. Fang 3452

Flow Field Simulation in Water Washing Tank of Explosion-Proof Diesel
R.S. Long, Z.S. Lian, S.N. Sun and Q.L. Wang 3456

Research on Jet Current Field Characteristic under Waves by Numerical Modelling in Flowing Ambient Fluid
M.C. Li, Q. Si and Y. Wang 3460

Feedforward Improved PID Algorithm to Control the Smart Car
Y.H. Xie and X.Q. Liu 3464

Evaluation of Various Turbulence Models in Predicting Airflow and Turbulence around a Generic Vehicle Model
C. Wu, Y.P. Wang and X. Yang 3468

Ground Simulation Method for Envelope Performance of Airship in near Space
L.B. Liu, P.P. Mi, S. Cao and M.Y. Lv 3473

Based on 3-D Modeling and Value Simulation of the Intake System in CNG
J.H. Li and J.J. Li 3477

The Metabolic GM (1,1) Prediction of the Absolute Gas Emission Quantity in a Certain Mine
X.Y. Meng, R.H. Chen and S.B. Wang 3480

Numerical Analysis of the Wind Tunnel Effect on the Chinese Kang in the Northern China
Z.L. Lu, Y.H. Xu, H.L. Wang and D.D. Xi 3485

Photometric Data Procession of the Swift/UVOT Instrument
X.P. Li, C. Yang, L. Zhou and H.T. Yang 3489

Process Simulation and Parametric Analysis of Gas Fractionation Unit
Q.R. Li, P. Li and P. Zhang 3493

Design and Simulation of Airborne Circular Omni-Directional Slot Antenna
L. Ren, Y.Z. Zhu, D. Su and X. Deng 3497

Based on Small Current Grounding Fault Analysis and Testing
H.L. Lv 3501

Prediction Model of Silicon Content in Blast Furnace Hot Metal Based on Artificial Neural Network and Genetic Algorithm
Y.H. Cheng, C.W. Niu and Y.X. Zhang 3505

Comparison of Two Computing Method on Thermal Conductivity of Aluminum Nitride
X.M. Cai, Q.N. Zhou and J.M. Wang 3509

Numerical Simulation and Experimental Study on Thawing Time of Cylindrical Frozen Food
A.M. Ji, X.C. Niu, B.N. Tang and F.L. Li 3513

Chapter 7: Communication, Signal and Image Processing, Data Acquisition and Recognation Technologies

A Modified DFT-Based Channel Estimation Method for OFDM-RoF System
L.Q. Huang, P. Zhang and G. Yang 3521

Dual Station Based Bearings-Only Tracking Using Unscented Filter
H.W. Quan, J.H. Li and M.S. Chen 3526

Mobile Wireless Communications Device with Buffered Cock Distribution Network
J.P. Jia, C.S. Wu, J.W. Chen and Y.Q. Shi 3530

POS Supported ADS40/80 Imagery Direct Geo-Positioning and Positioning Accuracy Optimization

Orthogonal Discrete Frequency-Phase Waveform Design Based on Hybrid Chaos for MIMO Radar
Y.N. Xie and J.J. Wang 3621

The Communication Capability of Shipboard Radio Based on Path Loss
X.G. Huang, A.M. Zhu and S.J. Yao 3625

Study of Synchronization Strategy Based on Timestamp
L. Xu 3629

Research on Multi-Sensor Data Aggregation Based on Clustering Analysis and Correlation
X.C. Dang, Q. Gao and Z.J. Hao 3633

Automatic Registration between High Resolution SAR Image and GIS Road Network Based on Pairwise Constraint and ICM Optimization
H.G. Sui, F. Hua, G. Chen and C. Xu 3639

Semi-Automatic Extraction Method for Low Contrast Road Based on Gabor Filter and Simulated Annealing
G. Chen, H.G. Sui, L. Dong and H. Sun 3644

Multi-Threshold Image Segmentation Based on Improved Particle Swarm Optimization and Maximum Entropy Method
Y.T. Lu, W.L. Zhao and X.B. Mao 3649

Speech Enhancement Based on EMD and Wavelet Threshold in Noisy Environments
Z.Q. Chen, D.X. Zhang and D.L. Yuan 3654

Study of SC-FDMA Reduce PAPR Based on the Power Line Carrier Communication
G.J. Gong, D.K. Hao, Y. Zhang, J. Lu and G. Xu 3658

An Improved Image Stitching Algorithm
D. Li 3663

Speech Airflow and Air-Pressure Signal Editing Platform
S.L. Lv and Y.S. Jin 3667

Modeling Difficult-to-Measure Process Parameters Based on Intrinsic Mode Functions Frequency Spectral Features of Mechanical Vibration and Acoustical Signals
J. Tang, Z. Liu, Y.J. Wu and L.J. Zhao 3671

Image Retrieval of Self-Adapt Distance Measure Based on SLLE
X.F. Wang, H.N. Zhang, X.R. Qiu, J.P. Song and K.X. Zhang 3675

Study on Deep Structure of Extreme Learning Machine (DS-ELM) for Datasets with Noise
M.M. Ma and B. He 3679

Design of 2_DOF Simulation Platform for the Testing of Airborne Laser Communication APT System
L.X. Meng, D.X. Zhao, Y.Y. Bai and L.Z. Zhang 3683

The Method of Optimal Group Based on the Kernel Density Estimation and the Close Degree
F. Ye, X. Wang, D.H. Peng and C.H. Jiao 3689

Research of Frequency-Hopping Communication for Arbitrary Array Based on Adaptive Beam-Forming
C.L. Qiao, H.D. Quan and P.Z. Cui 3693

Research on Fabric Image Acquisition Based on Compressed Sensing
J.C. Dong, S.Q. Guan and L.L. Chen 3698

Adaptive Equalization with Variable Step Size Algorithm Based on Gradient for HF Channel
F.F. Han and Z.H. Lin 3702

Joint Estimation of Doppler and Time Delay of Wideband Echoes for LFM Pulse Radar Based on Fractional Correlation in Impulse Noise Environment
L. Li 3706

Parameter Estimation Based on Fractional Correlation under Alpha-Stable Distribution Noise Environment in Bistatic MIMO Radar System
L. Li 3710

Multi-View Video Coding Based on Video Correction
T. Yan, X.X. Zhou, W.T. Luo, Z.L. Liu and P.D. Zhang 3714

De-Noising of Underwater Acoustic Weak Signals Based on Compressed Sensing Technique
L.L. Zhao and X.W. Dai 3718

A Beam Forming Method Based on Amplitude Weighting of Uniform Circular Array
J.L. Wang, Y.Q. Fu and X. Liu 3722

Impulse Noise Suppression Method for Telemetry Signal by Multi-Scale Median Filtering
X.F. Liu 3726

Research on Color Vegetable Diseases in Greenhouse Image Pretreatment and Extraction Method
X.L. Luo 3730

An Infrared and Visible Images Fusion Algorithm Based on Wavelet Multi-Resolution Decomposition
L.K. Liu and Z.J. Wu 3734

Simulation Research on Rolling Element Bearing Fault Signal Extraction Based on Blind Source Separation
Y.X. Zhang, J.P. Zhu and S. Zhang 3738

The Improved Membership Matrix Initialization Method of FCM for Image Segmentation
Z.J. Wu and L.K. Liu 3743

Discovering Frequent Itemsets an Improved Algorithm of Bit Vector and Graph
N.L. Liu 3747

An Improved Otsu Image Segmentation Algorithm
Y.X. Dong 3751

Radar Compressed Sensing Imaging Method with Two-Dimensional Separable Sampling
S.H. Jiao, L. Tang, X. Liu and H. Qi 3755

A MMSE Channel Estimation Method in QC-LDPC Coded OFDM Systems
G. Sangirov, Y.Q. Fu and Y. Fang 3759

Novel Infrared and Visible Images Fusion Algorithm Based on NSCT
H.F. Tan, T.W. Luo, J.J. Zhu, G.Z. Li and Q.X. Zhang 3763

A Novel Text Extraction Method from Pure Text Images Using Morphological Operations
X.Q. Chen, B. He, G.C. Wang and Y.X. Li 3768

Long-Range Communication Scheme Based on Majority Combing
Y. Peng, X. Huang, L. He and Y.P. Cui 3773

Electromagnetic Scattering from Perfectly Conducting Periodic Rough Surfaces Using Improved Complex Images Method
L. Li and W.C. Zheng 3777

Application and Analysis of the Full-Wave Band CCD System in Image Interpretation Technology
W. Han, J. Xie, J.H. Bao, M. Zhao, X.Y. Fan and F. Guo 3782

An Improved DFT-Based Channel Estimation Algorithm for OFDM System on Time-Varying Multipath Fading Channels
X.L. Ma, T.L. Fan and Y.F. Du 3786

Flattop Broadband Wavelength Conversion Based on Cascaded Second-Harmonic Generation and Difference Frequency Generation in Step-Segmented Quasi-Phase Matched Gratings
H.D. Wu, J.S. Guo, Y.W. Wu and Z.X. Wang 3790

Investigation of Efficient Wavelength Conversion Based by Difference Frequency Generation in Step-Segmented Quasi-Phase Matched Gratings
J.S. Guo, H.D. Wu, Y.W. Wu and Z.X. Wang 3794

Wavelet Transform Adjustment Method Study in Color Image Enhancement
Z.G. Zhang, S.Q. Yan and P. Geng 3798

Accurate Detection of Fault Signal in Large-Scale Communication
N. Shu 3802

Long Reach 10-Gbps WDM-PON Based on Carrier Distribution and Coherent Detection for Upstream Transmission
J.H. Liu, Y.P. Ma, S.R. Ren, Y. Yang and B. Zhang 3806

Analysis on Signal Extraction under Sudden Changing Noise Interference Based on Time Frequency Analysis
S.H. Nie 3810

Application and Research of Data Mining Technology in Communication Network Environment
Z. Zhang 3814

Study on Optimal Design Approach of One-Card under Multi-Signal Conflict
H.J. Zhu and Z. Wang 3818

Design and Simulation of Wireless Communication System Channel in Coal Mine Based on OFDM Technology
R.H. Ma 3823

Astronomical Image Matching Based on the Cross-Correlation Algorithm
J.J. Sun 3827

Dynamic Simulation of TT&C Signal Based on VFD Filter
W.G. Yang, W. Li and J. Zhao 3834

Enhancement Algorithm of Color Fog Image Based on the Adaptive Scale and Multi-Parameter Correction
Y. Gao, L.J. Yun, J.S. Shi and F.Y. Cheng 3838

3-D Reconstruction of Image Sequence Based on Independent Three-View
C. Li, H.R. Zhao and G. Fu 3844

Study on Enhancing Terminal Identification in Track and Field Using Digital X-Ray Photography Image
G.J. Lai 3851

Track and Field Image Segmentation Technology of Automatic Multi-Threshold Block Sampling Based on Matlab
A.L. Yu 3856

The Design of Image Acquisition System Based on CMOS Image Sensor USB Interface
Z.Y. Hu and L. Li 3861

Locating Method of DPM 2D Barcode Image
H.R. Zheng, B. Shan and Z. Liu 3865

The Simulation of DS-UWB RAKE Receiver over the Multipath Channel
K. Zhang, Y. Cao, C.F. Li and W.Y. Liu 3868

Video Sequences Foreground Enhancement Using Hidden Markov Model
D.Y. Lv, D.Y. Liu, Z.P. Huang, N.H. Yu and J.K. Wu 3872

The Study of a Fast Sub-Pixel Registration Method for Remote Sensing Image
C. Zhou, J.H. Zhou and D.H. Fan 3877

The Study of Combination Filtering for Removing Mixed Noise of Remote Sensing Image
C. Zhou, J.H. Zhou and D.H. Fan 3881

Hyperspectral Image Classification via Discriminative Sparse Representation with Extended LBP Texture
Y.M. Ren, Y.N. Zhang and W. Wei 3885

Channel Reservation Strategies for Multiple Secondary Users in Cognitive Radio Networks
Q. Peng, Y. Jiang, G. Liu, F. Cui, G.B. He and W.M. Wu 3889

New Enhancement Algorithm of Infrared Images Based on Dual Threshold of the Exponential Transform
J. Lv, J. Lv, C.F. Wu, Y. Zhou, F.P. Sun and K. Che 3893

Novel Single Image Dehazing Algorithm
J.P. Chen, D.Y. Bi, C. Liu and Z.L. Fan 3898

Simulation and Application of Space-Time Coding in OFDM System in Coal Mines
J.X. Wei and C. Sun 3902

Digital Image Technology Mineral Feature Extraction Method Research
J. Peng and D.B. Li 3906

Image Compression Technology Reseach Based on Lifting Wavelet Transform
R. Guo, Y.F. Li and F. Liu 3910

Optimization of Traffic Signal Timings Based on Surrogate Measures of Safety
Y. Zhang, C.C. Zheng, L. Zhang, X.R. You and D.X. Cheng 3915

Research on the Key Technology of Laser Engraved Image
S.Q. Zhang, D.M. Zhang and Q.H. Feng 3919

Study of PCM/FM Telemetry Sequence Soft Demodulation
D.X. Zhu, G. Fu and Y. Feng 3922

Study of Reentry Telemetry Signal in the Environment of Soft Demodulation
G. Fu, M. Tao and Q. He 3926

Research on Continuous Phase FM Signal Demodulation Based on STFT
Y. Feng, G. Fu, R.L. Li and L.P. Wang 3930

An Adaptive Filtering Method for Chirp Signal Based on FRFT
Y.J. Wu, G. Fu and G. Cheng 3934

Research on FM Telemetry Software Demodulation Algorithms
G. Fu, Y.J. Wu, R.L. Li and L.P. Wang 3938

Performance Analysis on Three Methods for Chirp Signal Parameters Estimation Based on FRFT
Y.J. Wu, G. Fu and P. Yu 3942

Group Sparsity Regularization Based Compressed Sensing MR Image Reconstruction
X. Jin, M.F. Jiang and J. Feng 3946

Pulse Coding Soft FM Telemetry Signal Demodulation
Y.J. Wu, G. Fu and G. Cheng 3952

Design of High-Speed Data Collector of Blast Wave Signal Based on the Post-Trigger Principle
X.G. Tang 3956

On Matlab's Simulations in Underground Mobile Multipath Channel
J.X. Wei 3960

Clutter Modeling and Characteristic Analysis for Airborne MIMO Radar
L. Hao, Y.S. Zhang, Z. Li and J. Xu 3963

Recognition of Paper Currency Research Based on AGA-BP Neural Network
X. Xiao, Q.H. Wu and Y. Zhang 3968

Wavelet De-Noising Algorithm Based on OpenCV for Images Edge Detection
Y.F. Ma and S.G. Liu 3973

A New Method of Multi-Component Chirp Signal Array Detection
G. Fu, Y.J. Wu and H.T. Tao 3977

Demodulation Method of Telemetry Signal Based on Virtual Radio
X.L. Yao, G. Fu and R.L. Li 3981

Multi-Frequency Estimates Based on IIR Adaptive Frequency Estimator
M.X. Kou, J.H. Lin and G. Fu 3985

Detection and Parameter Estimation of Chirp Signal Based on Time-Frequency Analysis
G.Z. Wu, G. Fu and Y.J. Wu 3989

Parameters Estimation and Waveform Reconstruction of Chirp Signal Based on FRFT
Y.J. Wu, G. Fu and F. Liu 3993

Research on Demodulation of Pulse Code Modulated Signal Based on Instantaneous Frequency Measurement
G. Fu, Y.J. Wu and Y. Feng 3997

LFM Signal Detection Method Based on Fractional Fourier Transform
Y.J. Wu, G. Fu and Y.M. Zhu 4001

Interference Suppression of VLF Communications in Atmospheric Noise
Y.J. Wu, G. Fu and W.J. Geng 4005

Research on Joint Time-Frequency Analysis Methods of Adaptive Radar Signal
Q. Xing, W.G. Zhu, Y. Bo and K. Wang 4009

A Study on Same-Beam Interferometry in Deep Space
X.Y. Wang, J.C. Hong and K. Hu 4014

The Application and Simulation of OFDM Technology in Power Line Communication
Y.W. Chen, B. Xu and J.H. Hao 4019

Research on Demodulation of High Bit Rate Telemetry Signal in FM Baseband
L. Yi, G. Fu and G.Z. Wu 4023

Study on Identification Method of Zherong Radix Pseudostellariae with Near-Infrared Spectroscopy
Y.P. Pang, K. Liu, L.Y. Xia and S.L. Yu 4028

Color Image Segmentation Based on Secondary Watershed and GrowCut Algorithm
J.M. Chen and H.Y. Lu 4032

Tracking Optimization of FH Signal Based on Wiener Filtering
Q. He, G.Z. Wu and Y.J. Wu 4038

Detection of Nonlinear Frequency Modulated Signal Based on Fractional Fourier Transform
Y.J. Wu, M. Tao and M.Q. Zhou 4042

Detection of Chirp Signal with Time-Varying Amplitude Based on FRFT
Y.J. Wu, R.L. Li and X. Wang 4046

Analysis on Ranging and Velocity Measurement Performance of DS/FH Hybrid Spread Spectrum Signal
Y.J. Wu, X.L. Yao and J. Xia 4050

Research of Image Denoising Method about Wavelet Transform with Neighborhood Average
C. Huang 4054

Application and Debugging of All-Digital Frequency Synthesizer
H.B. Fan, X. Meng and J.M. Hou 4058

Electronic Satellite Scheduling Problem and its Heuristic Method
J.C. Li, L.N. Xing, Y.W. Chen and X.Y. Wei 4062

Recent Improvements in Image Retrieval
Y.S. Zeng and X.L. Ying 4069

Mineral Belt Image Segmentation Using Firefly Algorithm
L.F. He, X. Tong and S.W. Huang 4074

The Hidden Terminal Problem of 802.11 MAC and 802.15.4 MAC Protocols Based on NS2 Platform
D. Qiu and Y.X. Yang 4078

Research on Halftone Technique of Digital Images
W.B. Dai, L. Chen, X.W. Zhang, L. Wang, S.Y. Nie, K.J. Yang and Y.W. Wang 4082

Research and Implement of Digital Image Watermark Based on DCT
L.Y. Liu 4086

Face Recognition Based on Gabor Filter and Improved Linear Local Tangent Space Alignment Algorithm
X.Y. Xu, J.Y. Liu, Y. Shi and T. Deng 4091

A New Way to Optimize LDPC Code in Multiple Access Channel
J.X. Zhang 4095

A Study and Design of Compressed Encoder Based on Neural Network for Remote Sensing Image
L. Tao, W.L. Li, Y.Y. Yu, J. Kang and J. Yang 4100

A New Method of Image Matching in a Vision-Based Mobile Robot System
C.Z. Cao, W.Z. Gao and H.J. Li 4104

The Research of Starry-Sky Image Bright Stray Light Background Suppression Method
S.J. Guo and Z. Wang 4107

Body Surface to External Channel Modeling
Y.H. Yang, L.F. Wang, D.Y. Shen and M. Yang 4111

Research and Solution on Bottleneck Problem in Zigbee
J.P. Zhang and X.L. Zeng 4115

A Image Decomposition Method Based on Euler Mapping for Face Recognition
Z.K. Li and Y. Wang 4119

Color Space Comparison between RGB and HSV Based Images Retrieval
C.H. Su, H.S. Chiu, J.H. Hung and T.M. Hsieh 4123

Blind Detection of Copy-Move Forgery in Digital Images Based on Dyadic Wavelet Transform
R.F. Zhang, H.M. Ye, Z.H. Song and M. Wang 4127

The Realization of Receiving and Reporting the HARQ-ACK Information in LTE System
P. Sun, J. Yang, Y.J. Chen and C. Zhou 4132

NSCT-Based Image Enhancement Combing Homomorphic Filtering with Fuzzy Theory
K. Wen, B. Sun and J. Yang 4136

Realization of Book Locating by RFID Technology in Mobile Phone Libraries
Y.P. Wang 4140

Design of a Novel Variable Bit Rate Video Traffic Prediction Model Based on Neural Networks
Z.Z. Lian, H.Z. Wang and D.H. Li 4143

The Application of Physical Layer Network Coding in the UAVs
Z.M. Yang, Y.J. Hu, C.L. Wang and Q.S. Yuan 4147

Study on the Implementation of RAKE Receiver in 4G System
H.Y. Fu, C.R. Zhu and X.D. Jia 4152

The Research of M-Learning Platform Based on 4G Network
H.Y. Lin and Y.J. Wang 4157

3D Human Body Data Acquisition and Fit Evaluation of Clothing
Z. Wang, Y.Q. Zhong, K.J. Chen, J.Y. Ruan and J.C. Zhu 4161

Design and Implementation of Telemetry Data Post-Processing System
X.C. Wu, G. Fu and R.L. Li 4165

An Energy-Efficient Three-Dimensional Positioning Technology for Underwater Acoustic Wireless Sensor Network
X.Y. Wei, C. Zhu and S.D. Qiao 4169

Electric Power Communication Network Alarm Data Acquisition System Based on CORBA Northbound Interface
Y.J. He, Y. He, P. Peng and R. Chen 4175

Robustness Analysis of Telecommunications Customer Service System
B. Wu 4179

A Novel Public Key Image Cryptosystem Based on Elliptic Curve and Arnold Cat Map
L.J. Chen and A.D. Shen 4183

Research on Adaptive Face Gender Recognition Based on Compressive Sensing
L. Zhang 4187

The Application of a New Demodulation Technology in the Telemetry System
M. Tao, G. Fu and G.Z. Wu 4191

Digital Signal Processing Approach of Dithered RLG Based on IFIR Digital Filter
K. Zhang, G.L. Yang, W.Z. Zheng and R.D. Ma 4195

A New Framework for Churners' Influence Analysis Using Call Data Records
O.O. Georges, S.Q. Cai and Q. Yuan 4200

A Robust Image Preprocessing Algorithm for Face Recognition
Y. Wang and Z.K. Li 4205

Feature Representation Method Based on Kirsch Masks Filter for Face Recognition
Z.K. Li and Y. Wang 4209

Chapter 8: General Principles of Information Technology, WEB and Networks Engineering, Information Security, E-Engineering, Software Application and Development

Research to Household Sub-Network Development Based on Bluetooth Control Technology

Keywords: Vanadium Slag; Vanadium Titanium Catalyst; Zeolite 4A; Adsorption

Abstract. Vanadium slag is a kind of common furnace slags in the metallurgical field that contains rich vanadium oxides and iron oxides. The high value added utilization of vanadium slag was exploratory studied in this paper. Under the existing experimental conditions, chemical reactions conducted between vanadium slag and concentrated sulfuric acid. Vanadium titanium catalyst was prepared with the lixivium(whose main ingredients were 44.42% of V_2O_5 and 29.36% of TiO_2), which could meet the demand of industrial production; zeolite 4A was prepared creatively with leach residue of vanadium slag for the first time and its feasibility in CO_2 capture was verified via detecting the CO_2/N_2 adsorption capacity. It is feasible to recycle solid wastes efficiently, reduce the environmental pollution and promote the development of CO_2 reduction technology by this means.

Introduction

Vanadium slag is a kind of furnace slags that contains rich vanadium oxides and iron oxides, whose vanadium content largely depends on the contents of vanadium and impurity elements(Si, Mn, Ti, Cr, etc.) in the molten iron[1]. Currently, its main application lies in extracting the vanadium in it, but problems such as after baking, high energy consumption and environmental pollution still exist.

In terms of vanadium extraction. Peng Yi, Zhu Shengyou et al.[2] proposed a method via calcium roasting, which avoided the environmental pollution during the decomposition of sodium salt. LU Zhao-ling[3] reported a process of direct acid leaching of vanadium, whose leaching rate of vanadium reached 80%. FENG Qi-ming[4] researched the influence factors in high pressure acid leaching of vanadium and found that oxidizing agent would play a promoting role in the process.

In recent years, extensive research has been devoted recently to CO_2-capture techniques because of growing concerns with respect to greenhouse gas emissions[5][6]. Zeolite molecular sieves are those natural and synthetic crystalline aluminosilicates with molecular sieving effect[7]. Various cheap raw materials were used in preparation of zeolite. Xu Guoxiang et al.[8] provided the methods to prepare zeolite by alkali fusion, Wu Qisheng et al.[9] took coal series kaolinite as the principal raw material. Moreover, raw materials in relevant studies involved coal gangue, oil shale, etc.

Although there have been some new processes related to acid leaching of vanadium, no similar report exists in direct acid leaching for vanadium slag as well as in synthesizing zeolite with vanadium slag. In this study, vanadium slag of BOF(Basic Oxygen Furnace) from Panzhihua was taken as the raw material and leached directly via acid leaching. Then, vanadium titanium catalyst would be prepared with the lixivium and zeolite 4A would be prepared with the SiO_2-rich leach residue via alkali fusion-hydrothermal method as well. In summary, vanadium slag could be utilized efficiently and profitably with this approach.

Experiments

In acid leaching of vanadium slag, vanadium slag of BOF from Panzhihua was taken as the raw material and the other chemicals used were analytically pure. To begin with, the vanadium slag was levigated and placed in a customized round-bottomed flask. A certain amount of sulfuric acid, whose concentration is 50%, was injected in the flask until the liquid-solid ratio reached 3:1. Then, the mixed solution was heated and stirred under 140℃ for 3.5h. The above reactant, after the reaction, was filtered for two times and residue get in filtration was put into the drying oven and weighed.

In preparation of vanadium titanium catalyst, hydrogen peroxide was gradually added in 50mL prepared solution(concentration of vanadium ion was 0.260mol/L) until the lixivium was near colorless. Then, aqueous ammonia was added dropwise after 10 minutes' standing each time so that the reactions could proceed adequately. The pH was adjusted and the first precipitates were filtered, dried and calcined after 1h of stewing. At the same time, aqueous ammonia was continuously added into the filtrate until the pH reached 8. Finally, the filtrate was filtered and dried under 100℃ for 3h and the second precipitates was put in high-temperature furnace to roast under 600℃ for 1h.

In the preparation of zeolite 4a with leach residue, residue from acid leaching of vanadium slag was used in preparing zeolite 4A. $NaAlO_2$ was taken as aluminum source and NaOH was added according to the alumina ratio of 2, NaO_2/SiO_2 ratio of 3.5. Next, the liquor was stirred evenly in porcelain boat and put in high-temperature furnace to roast under 600℃. Water and certain quantity of $sNa_2Al_2O_4$ were then added. The mixture was stirred, moved into stainless steel reactor and sealed. In drying oven, precipitation crystallization proceed at 95℃ for 12h. Finally, the mixture was filtered and washed until neutral. Since then, zeolite product was obtained after dried at 100℃.

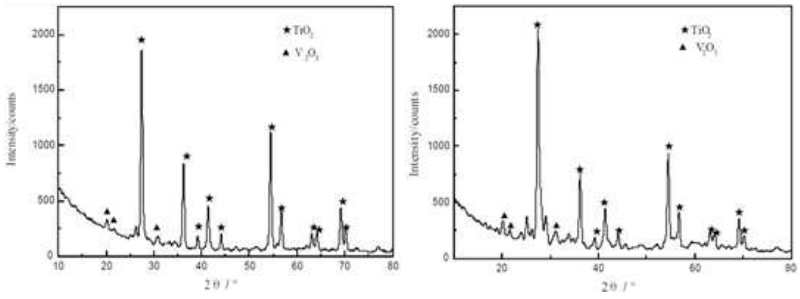
Results and Analysis

According to X-ray fluorescence spectroscopies of the first precipitate and the second precipitate(Table1), there are greater contents of vanadium and titanium while no much iron in the first precipitates under stronger acidity. By contrast, there are greater contents of iron oxide and manganese oxide while no much oxide of vanadium and titanium in the second precipitates.

Table1 Chemical Compositions of Precipitated Materials（mass, %）

Chemical Composition	V_2O_5	TiO_2	Fe_2O_3	Cr_2O_3	Al_2O_3	MnO	Others
Content(The first precipitates）	44.42	29.36	12.47	6.43	3.34	2.73	1.25
Content(The second precipitates）	14.24	12.47	39.46	1.46	2.37	28.77	1.23

Fig.1 is the XRD patterns of precipitates. There are apparent characteristic peak of rutile TiO_2 and tiny diffraction peak of V_2O_5 in both patterns, which indicates vanadium, at the moment, might exist in the forms of polymer, monomer or amorphous state. It might also be that polymer of the V_2O_5 crystal here is tiny in size and small in quantity so the diffraction peak detected by XRD appears pretty weakly[10]. No obvious diffraction peak of iron oxide or manganese oxide could be found in each pattern, which indicates there are less impurity contents in products.



the first precipitates　　the second precipitates

Fig.1 XRD Patterns of Precipitates

The prepared zeolite 4A was analyzed via X-ray fluorescence spectroscopy(as shown in Table2). On the basis of contents of SiO_2, Al_2O_3 and Na_2O in Table2, the ratio of these three parameters is

close to 1:1:1, which is extremely analogous with the chemical formula of zeolite 4A. It can be seen that we have successfully prepared zeolite 4A via the means offered in this paper.

Table2 Chemical Compositions of Zeolite 4A (mass，%)

Chemical Composition	SiO_2	Al_2O_3	Na_2O	Fe_2O_3	CaO	TiO_2	MnO	Others
Content	32.8	28.7	17.8	9.8	3.8	3.1	2.5	1.5

Furthermore, we detected the obtained zeolite 4A via SEM(as shown in Fig.2). The SEM images demonstrate the synthetic zeolite 4A has formed intact cubic crystal and the particle size of samples is 5μm or less. The finished zeolite 4A exhibits uniform particle size and intact crystal of regular hexahedron structure, which is consistent with literature reports. Moreover, the SEM images intuitively reflect the crystallinity of products and indicate the obtained zeolite 4A enjoys high purity and uniform particle size.

In order to analyze the CO_2/N_2 separating property, we utilized Agilent 409 PC thermogravimetric analyzer to measure its adsorption curves under the temperature of 60℃ and 30℃(as shown in Fig.3). Fig.3(A) shows the CO_2/N_2 adsorbing capacity of obtained zeolite 4A at 60℃ under normal pressure, which is respectively 2.402mmol/g and 0.446mmol/g. Fig.3(B) exhibits that, at 30℃ under normal pressure, its CO_2 adsorbing capacity is 3.772mmol/g and N_2 adsorbing capacity is 0.568mmol/g. It can be seen from Fig.3 that huge gap exists between its adsorbing capacities of the two kinds of gasses. We could also figure out by comparing the two figures that the falling range of CO_2 adsorbing capacity is much larger than the other one when the temperature rises from 30℃ to 60℃. In other words, impact effects of temperature are different to adsorbing capacities of CO_2/N_2: the obtained zeolite 4A shows better CO_2/N_2 adsorbing capacity at 30℃ compared to that at 60℃.

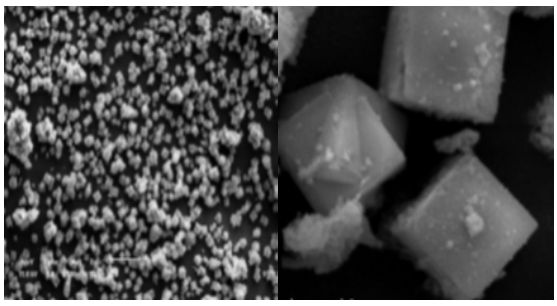


Fig.2 SEM Images of Zeolite 4A

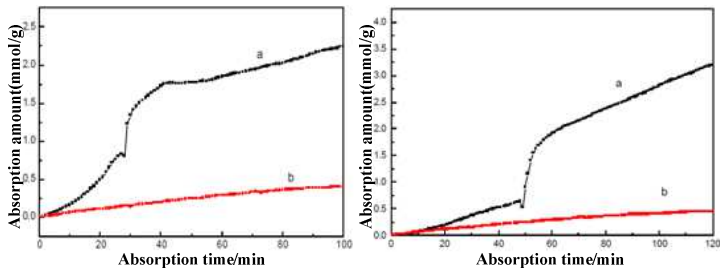

Fig.3 CO_2(a) and N_2(b) Adsorption Isotherms on Zeolite 4A at 60℃(A) and 30℃(B)

Conclusions

In this paper, we exploratory studied on the high value added utilization of vanadium slag.

1) Chemical reactions conducted between vanadium slag and concentrated sulfuric acid. According to XRD analysis, main ingredients in the first precipitates are 44.42% of V_2O_5 and 29.36% of TiO_2 and there are less impurity contents in products.

2) Zeolite 4A is prepared with the leach residue of vanadium slag, which has opened a totally new channel in zeolite preparation. By means of analyzing the adsorption curve of zeolite 4A, it could be found that the CO_2/N_2 adsorbing capacity of it, at 30℃ under normal pressure, is respectively 3.772mmol/g and 0.568mmol/g and thus its feasibility in CO_2 capture has been verified.

3) The utilization of vanadium slag offered in this paper could well solved the problems such as after baking, high energy consumption, environmental pollution, etc. It is achievable to recycle solid wastes efficiently, reduce the environmental pollution and promote the development of CO_2 reduction technology.

Keywords: Laterite nickel slag; Zeolite 4A; Crystallinity; separation of CO_2/N_2

Abstract. Laterite nickel ore is a kind of abundant and low-cost ore. In order to obtain the cheap and high-performance adsorption material, this paper addresses that Zeolite 4A was synthesized by laterite nickel slag, based on two-step hydrothermal synthesis procedure and alkali-melting process. The crystallization degrees of different kinds of Zeolite 4A were explored under different ratios of the reactants. Optimal condition was found out for synthesis of Zeolite 4A, including the ratios of the reactants. Finally, Zeolite 4A obtained under the optimal condition was tested by XRF, NOVA 1200e physical adsorption analyzer, and SEW separately, which confirmed its high purity and complete crystals. Finally, separation of CO_2/N_2 by Zeolite 4A using STA409PC Physical adsorption instrument was studied, revealing good adsorption selectivity which became lower with rising temperature.

Introduction

With the increasing consumption of fossil fuels, CO_2 emission is rising rapidly, resulting in serious global warming. Therefore, Carbon capture and storage plays an important role in the protection of environment. Meanwhile, it is also vital for humans to study and exploit adsorption material which is high-performance, cheap, and green. Zeolite 4A consisting of polyhedron is a kind of adsorption materials which are synthesized by cheap and industrial waste materials[1]. As crystal of Zeolite A contains huge coulomb field and polarity effect, Zeolite 4A has strong adsorption capacity which can absorb a great number of molecules and ions of small diameter less than 0.4nm[2]. Now, there are no reports Zeolite synthesized by laterite nickel slag. In the case of adding $NaAlO_2$ as aluminum source, this paper developed a new process to synthesize Zeolite using laterite nickel slag as silicon source, combined with two-step hydrothermal synthesis procedure[3] and alkali-melting process[4]. That process not only made full use of silicon in laterite nickel slag, but also got high purity Zeolite 4A.

Preparation of Zeolite 4A

After magnetic separation, laterite nickel slags mainly include SiO_2 with a few impurities. The main ingredients were presented in Table 1.

Table 1 Chemical composition of laterite nickel slag

Ingredients	SiO_2	Fe_2O_3	MgO	Al_2O_3	K_2O	Others
Percentage(%)	83.84	4.59	2.79	2.25	1.30	5.23

When materials were acquired, the preparation steps for Zeolite were as following:

(1)Make the laterite nickel slags after magnetic separation pass through 200 mesh sieve, the finer slag, the higher hydrothermal degree;

(2)Regarding sodium hydroxide as activator, the raw materials are calcined at 500 °C where crystallinity reaches the maximum for 2h[5];

(3)Add a certain proportion of deionized water and stir, then filter;

(4)Mix a specific ratio of $NaAlO_2$ to the extracted liquid slags to adjust Si/Al molar ratio;

(5)Add distilled water, and stir it 3h to be uniform with magnetic stirrer for further refined of materials and uniform distribution of water, and then plasticity index of mixture increase obviously, good for nucleation of Zeolite[6];

(6)Crystallize at constant temperature for 8h in 100°C dry box;

(7)Wash the crystalline product thoroughly until the filtrate pH reaches 9-10[7], and then dry it at temperature of 80°C in oven and ground it to pieces, namely Zeolite 4A.

Results and discussions

The concentration of NaOH, has immense impact on the crystalline product during the process of crystallization. NaOH not only is used in forming alkaline condition which compensates for excessive negative charge in Zeolite, but also take part in the synthesis of the Zeolite 4A directly in the hydrothermal system involving laterite nickel slag, $NaAlO_2$, sodium hydroxide and water[8].

In order to analyze the impact of H_2O/Na_2O on crystallization of Zeolite 4A, various kinds of Zeolite 4A, in the phase region generated Zeolite 4A, were integrated in different H_2O/Na_2O ratio, under the conditions: $n(SiO_2/Al_2O_3)$=2.4, $n(Na_2O/SiO_2)$=1.4. The ratios of H_2O/Na_2O were 45, 60, 75, 85, 110, 155, 200. Samples were named Al, A2, A3, A4, A5, A6, A7, and the corresponding crystallinity degrees were 92.7, 84.1, 89.7, 88.8, 93.9, 40.7, 22.3(%).

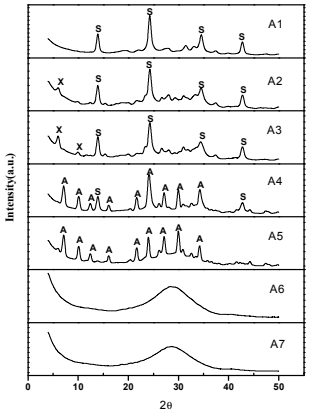

Fig.1 XRD patterns of 4A zeolites synthesized with different H_2O/Na_2O

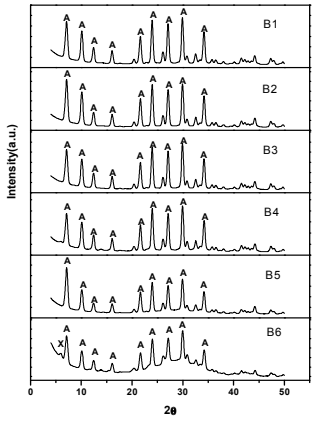

Fig.2 XRD patterns of 4A zeolites synthesized with different SiO_2/Al_2O_3

XRD patterns of 4A zeolites synthesized with different H_2O/Na_2O are shown in Fig. 1. Comparing these seven XRD patterns, it was showed that the higher alkalinity is, the more stable Sodalite is; Zeolite A is stable in a certain low alkalinity; when alkalinity is too low, it is not enough to synthesize Zeolite, but SiO_2. Hence, the optimum H_2O/Na_2O ratio of reaction is 110, with the highest crystallization accounting for 93.9%.

In general, under the other constant conditions, the higher silica-alumina ratio, the slower the crystallization does, and vice versa[9].

To study the effect of SiO_2/Al_2O_3 on crystallization of Zeolite 4A, the other reaction parameters were set as follows: $n(Na_2O/SiO_2)$=1.4, $n(H_2O/Na_2O)$=110. With the conditions, the $n(SiO_2/Al_2O_3)$ was set as follows: 1.5, 2, 2.5, 3, 3.5, 3.8, samples were B1, B2, B3, B4, B5, B6 respectively, and the corresponding crystallinity degrees were 96.1, 97.7, 96.0, 96.2, 96.9, 93.9(%).

Varying the quantity of $NaAlO_2$ to change SiO_2/Al_2O_3 relatively, XRD patterns of the productions were shown in Fig. 2. As seen in the picture, the characteristic peaks of Zeolite was the strongest and the most complete among all the characteristic peaks and the diffraction peak was clear and regular when $n(SiO_2/Al_2O_3)$ =2.0, which confirmed that the crystallization Zeolite 4A was the best at this time, corresponding with the result of experiment. Thus, the best SiO_2/Al_2O_3 ratio was 2.0.

In the process of crystallizing molecular sieve, Alkali participates in the system of aluminate and silicate ions in polycondensation reaction and improves the efficiency of crystalline reaction and

saves synthetic time [10]. The increasing sodium hydroxide can improve the dissolving capacity of water, which can increases the dissolution rate and concentration of silicate and aluminate ions in the reaction system and be good for zeolite's growth. So it is supposed to add sodium hydroxide in the preparation of molecular sieve.

For the purpose of researching the effect of Na_2O/Al_2O_3 on crystallization of Zeolite 4A, in the phase region generating Zeolite 4A, reactants condition was set: $n(SiO_2/Al_2O_3)$=2.0, $n(H_2O/Na_2O)$=110. The samples, namely C1, C2, C3, C4, C5, C6 with corresponding crystallinity degrees: 95.7, 95.8, 97.7, 96.1, and 96.3(%) under the condition that Na_2O/SiO_2 ratios were 1.2, 1.3, 1.4, 1.5, 1.6 correspondingly.

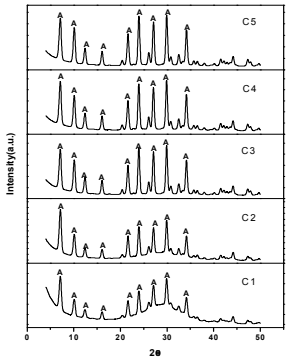

Fig.3 XRD patterns with different Na_2O/SiO_2

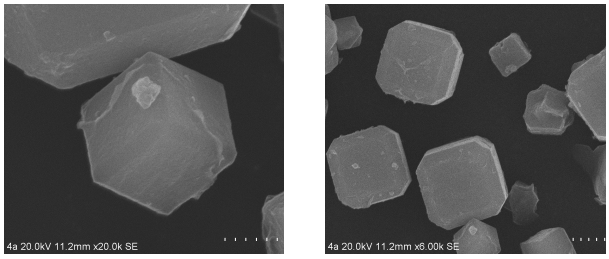

Fig.4 SEM images of zeolite 4A

Adjusting the amount of sodium hydroxide, Na_2O/SiO_2 ratio was changing simultaneously, which was depicted in Fig.3. Comparing the peaks, it is obvious that relative crystallinity increased to 97.7% along with Na_2O/SiO_2 ratio ranging from 1.2 to 1.4. Meanwhile, the characteristic peaks are stronger and stronger, and the strengths of diffraction peaks are higher and higher. But, after 1.4, the higher the Na_2O/SiO_2 ratio was, the lower the relevant crystallinity was. Consequently, the optimum n(Na_2O/SiO_2) was 1.4.

Characterization of Zeolite 4A

The XRF of Zeolite 4A showed that SiO_2/Al_2O_3 ratio was 1.94, closing to the best ratio confirmed by experiment: $n(SiO_2/Al_2O_3)$=2.0, which was corroborated silicon and aluminum had almost sufficient reaction. In addition, the product had few impurities, especially the contents of Fe_2O_3 and MgO, so the purity of Zeolite 4A was very high.

This experiment measured the specific surface area of Zeolite 4A using NOVA 1200e physical adsorption analyzer. The BET surface area of Zeolite 4A and Commercial Zeolite A were respectively 31cm^2/g and 300cm^2/g. The reason lay in pores of Zeolite 4A contracted so many that N2 molecules couldn't enter into it at 77K temperature.

SEM photographs in Fig.4 depict that 4A molecular sieves are typical cubic morphology and crystals are relatively complete, uniform dispersion and high purity, which corresponded with Zeolite 4A synthesized by Liu Liying[11] using fly ash.

The Separation of CO2/N2 of Zeolite 4A

Sorption isotherms were tested by STA409PC Physical adsorption instrument produced by NETZSCH at 30°C and 60°C respectively, which could show the adsorption capacity of Zeolite 4A to CO_2 and N_2, and judge the separation performance of CO_2/N_2 of Zeolite 4A further.

As is depicted in Fig.5, CO_2 and N_2 adsorption capacity of Zeolite 4A are 3.803mmol/g and 0.389mmol/g at atmospheric pressure and 30°C respectively, which reveals Zeolite 4A having a high adsorption selectivity on CO_2/N_2.

As is subtly portrayed in Fig.6, at 60°C and atmospheric pressure, adsorption capacity of Zeolite 4A to CO_2 and N_2 are 2.939mmol/g and 0.964mmol/g respectively, which indicates adsorption capacity to CO_2 is also much larger than that to N_2. Compared with the condition of 30°C, the adsorption capacity to CO_2 at 60°C is lower obviously. But the adsorption capacity to N_2

at 60°C is higher. Wherefore, as the temperature rises, the adsorption selectivity on CO_2/N_2 of Zeolite 4A gets down.

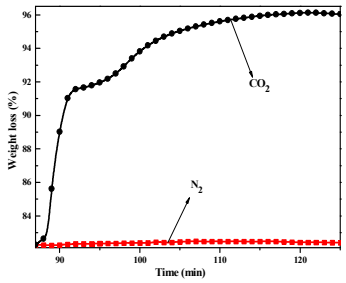

Fig.5 Adsorption isotherms of 4A at 30°C

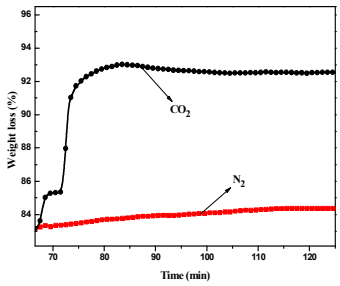

Fig.6 Adsorption isotherms of 4A at 60°C

Conclusions

(1)The optimal conditions of synthesizing Zeolite 4A using methods which associate two-step hydrothermal synthesis procedure with alkali-melting process are as follows: $n(SiO_2/Al_2O_3)=2$, $n(Na_2O/SiO_2)=1.4$, $n(H_2O/Na_2O)=110$.

(2) SiO_2/Al_2O_3 ratio was 1.94, which shown silicon and aluminum had almost sufficient reaction. The BET surface area of Zeolite 4A was 31cm^2/g. Zeolite 4A synthesized under the optimal condition has complete morphology and high purity.

(3) Zeolite 4A has a high adsorption selectivity on CO_2/N_2 at atmospheric pressure and 30°C. With the temperature rising, this performance weakens.

Keywords: Bismuth sulfide, hydrothermal, Preheating

Abstract. Bi_2S_3 flowerlike patterns were synthesized via a facile hydrothermal approach without using any surfactant and acid. The morphology, structure, phase composition, of the as-prepared Bi_2S_3 products were characterized using scanning electron microscopy, X-ray diffraction, high-resolution transmission and electron microscopy, respectively. The experimental results showed that the product possesses good distribution of morphology, well crystallized nanostructure.

Introduction

Semiconducting chalcogenides are materials which have attracted a great deal of interest. Bismuth sulfide (Bi_2S_3) is one of these materials which belongs to the family of main group metal chalcogenides A2VB3VI (A=As, Sb and Bi; B=S, Se and Te), an important class of semiconductors with numerous applications including photovoltaics, thermoelectrics and IR spectroscopy [1-3]. Recently, Bi2S3 nanoparticles have been found to be a promising imaging agents in X-ray computed tomography, electrochemical hydrogen storage and photosensor [4-6].

There have been several recent reports on synthesis of Bi_2S_3 nanostructures. The lamellar crystalline structure of Bi_2S_3 gives rise to the development of different 1D nanostructure under certain growth conditions [7]. Nanowires, nanorods, nanotubes, and nonoribbons have been produced by solvothermal or hydrothermal process [7-10], microwave irradiation approach [11], ultrasonic method [12], template-assisted pressure-injection technique [13] and so forth. More complex morphologies of Bi_2S_3 have been made by employing the soft template effects [14-17]. Since the physical properties and performance of Bi_2S_3 nanostructures could be tuned by different dimensions morphologies, it is attractive to realize the facile synthesis of Bi_2S_3 nanostructures with controlled morphologies.

Hydrothermal approach is an effective and economical method, which has been applied to prepare Bi_2S_3 with different structures by varying the reaction conditions. Na_2S, CS_2, sodium thiosulfate and dithiocarbamate have been used to react with bismuth salt at an elevated temperature and pressure. Phuruangrat et al. [10] has prepared Bi_2S_3 nanorods via hydrothermal method with bismuth nitrate and thiourea (NH_2CSNH_2) as starting reagents in acid solution without any surfactant. Acid concentration in the reaction plays an important role in controlling the morphologies of Bi_2S_3 nanostructures. In acid-free solution, the product obtained through hydrothermal process was irregular in shape [18]. On the contrary, the introduction of too much amount of acid results in the appearance of Bi_2S_3 nanoparticles [19, 20] because of dissolving of Bi_2S_3. It is not easy to control the morphology and crystalline of the product since the morphology of the product is quite sensitive to the acid. The acidity should be altered very carefully to obtain the desired nanostructures. Furthermore, the acid used in the reaction usually involves nitric acid and hydrochloric acid, which is contaminative to the environment. Therefore, the development of facile

and environmental friendly strategies without using contaminating acid for synthesis of Bi_2S_3 nanostructures is deemed necessary.

In this article, Bi_2S_3 were prepared by hydrothermal methods. The mixture of $Bi(NO_3)_3 \cdot 5H_2O$ and NH_2CSNH_2 solutions was preheated firstly and then hydrothermally processed in an autoclave. Through this method flowerlike Bi_2S_3 were synthesized without using any acid.

2. Experimental

All reagents were analytical grade and used as received without any further purification. To produce nanostructured Bi_2S_3, 2 mmol $Bi(NO_3)_3 \cdot 5H_2O$ and 6 mmol NH_2CSNH_2 powders were dissolved in 25 and 5 mL distilled water, respectively. Subsequently, the thiourea solution was added into the bismuth nitrate suspension under vigorous stirring. At this stage, the color of the solution turned from white to light yellow. The mixture was thoroughly mixed by stirring at 60 °C for 20 minutes before transferred into a Teflon-lined stainless-steel autoclave. The autoclave was sealed and maintained at 160 °C for 15 hours and then cooled to room temperature naturally. Finally, black precipitates were produced, which were separated, washed and dried, for further analysis.

The products were characterized extensively for morphology, phase, and growth direction by using scanning electron microscopy (SEM, JEOL, JSM-5600LV, Japan), X-ray powder diffraction (XRD, X'Pert Pro), selective area electron diffraction (SAED) and high resolution TEM (HRTEM, JEM-2010CXII).

3. Results and discussion

Fig.1 shows the XRD pattern of the as-prepared Bi_2S_3 products. All reflections in Fig.1 can be indexed to a pure orthorhombic phase bismuth sulfide (JCPDS file 65-2431) with lattice parameter a=11.29 Å, b=3.978 Å, c=11.15 Å. No characteristic of other impurities ($BiONO_3$, Bi_2O_3 and Bi, etc.) were observed. The intense diffraction peaks in Fig.1 indicates that the product should be well crystallized. This is further demonstrated by HRTEM and ED analysis.

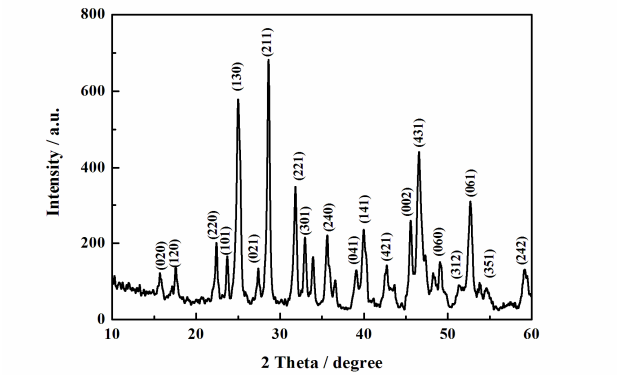

Fig.1 XRD patterns of Bi_2S_3 powder prepared in acid-free solution

Fig. 2(a) is typical SEM images of Bi_2S_3 synthesized by combination of preheating and hydrothermal process. SEM images of the as-prepared Bi_2S_3 nanostructures demonstrated that the sample is composed of flowerlike patterns in a well organized way. The typical size of the nanoflower is about 6 μm in diameter. As shown in Fig. 2(b), Bi_2S_3 nanoflower is constituted of nanorods with a diameter 50-100 nm and up to 1-2 μm long. These nanorods are all smooth, clean and without any amorphous phase in surface. Electron diffraction (ED) patterns of the Bi_2S_3 in Fig. 2(c) indicates that the nanorod is a single crystal and predominately grows along the [001] direction. The conclusion is also supported by the HRTEM observations in Fig. 2 (d), in which the clearly observed lattice fringes reveal that the Bi_2S_3 nanorods in the flowerlike patterns are highly crystalline. The crystal planes, parallel and perpendicular to the rod axis, having spacing of 0.8 and

0.4 nm, which match well with the separations between the neighboring lattices of (110) and (001) planes, respectively. This result further verifies that the preferential growth occurred along the [001] direction.

Thiourea has been used as sulfur source to control the morphological evolution of metal sulfides in the solution phase. As we know, $Bi(NO_3)_3$ has a strong tendency to hydrolyze in neutral solution and generate white $BiONO_3$ precipitation. As the addition of thiourea, thiourea coordinates to bismuth ions to form complexes, prevents the explosive production of bismuth sulfide and benefits the oriented growth of final nanorods. The H_2S generated by thiourea decomposition at high temperature will act with Bi^{3+} and produce Bi_2S_3. The generation of nanorods may involve the formation of "growing seeds" during the decomposition of the precursors, followed by the production of crystalline nanonuclei and preferential growth of [001]-oriented Bi_2S_3 nanorods. Bi_2S_3 precursor forms by preheating the reagents [22] at the first step. It is gradually crystallized by hydrothermal treating and act as the crystalline nuclei. Bi_2S_3 nanoparticles deposited from supersaturated solution grew on these nuclei cites gradually to form nanorod at a prior growing direction. In solution without preheating, however, the formed $BiONO_3$ precipitation will react with NH_2SCNH_2 to form irregular nanostructures. It may be attributed to fact that the Bi_2S_3 nanoparticles mushroomed under high temperature and pressure.

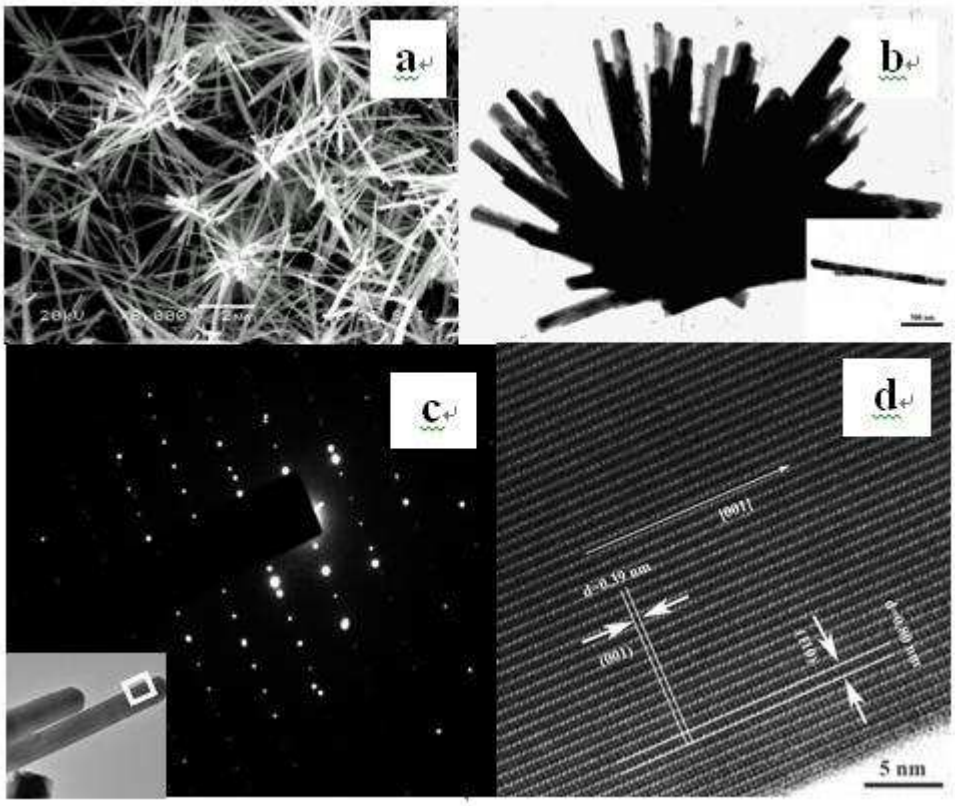

Fig. 2 (a) SEM image of the Bi_2S_3 flower pattern prepared in acid-free solution for 15 h (b) TEM images (c) is the ED pattern (d) HRTEM images.

Conclusion

In summary, preheating effect on the morphology of Bi_2S_3 nanostructures synthesized by hydrothermal method has been investigated. It provides a more controllable and environmentally friendly way to the Bi_2S_3 synthesis without using any surfactant or acid.

Keywords: eosin, ferrate, oxidation, pH

Abstract. This paper presents a comparative study of the performance of ferrate (VI) towards wastewater treatment. The effects of solution pH, reaction temperature and amount of ferrate on the eosin removal rate were investigated. Results demonstrated that increasing the amount of ferrate (VI) and low acidity leads to good removal performance of ferrate towards eosin. So ferrate (VI) is an effective reagent for dyes treatment. The reaction temperature, however, has little influence on the removal rate which may be due to the degradation effects of ferrate at elevated temperatures.

Introduction

Potassium ferrate, K_2FeO_4, is a strong and environmental friendly oxidant [1]. It has been attracting more and more research interest during the past decades. The redox potential of ferrate (VI) ions is as high as 2.2V and 0.72V under the acidic and basic conditions, respectively[2]. Ferrate is attracting growing attention for several water treatment applications because of the reagent's selective oxidizing properties. Additionally, the product of ferrate oxidation reaction is considered to be ferric hydroxide, which is useful coagulant and will enhance the water remediation performance. So it is a promising chemicals for treatment of waste water. The instability of ferrate solutions has limited its use in field treatment applications, but recent efforts are focused on developing technologies for on-site ferrate generation. The loss of ferrate due to the degradation during the storage and transport process would be avoided.

In recent years, various accelerated energy consumption and the unabated release of toxic agents into the air and water has led to such adverse effects as pollution-related disease and global warming. So, it is urgent to develop clean and safe chemical technologies, materials and process for environmental remediation. Eosin is an important acidic dye used as indicator. It dissociates in water into ions. Its negative ion, which is acidic in nature, readily combines with positively charged regions of cellular, macromolecules, proteins, colouring them a variety of hues, ranging from pink to red to orange.

In this article, eosin was used as a model pollutants. The oxidation effects of ferrate to eosin was investigated. Factors, such as pH value, temperature, the amount of ferrate, and so forth, that influence the reaction rate was explored.

Experiment sections

Experimental materials

K_2FeO_4 was prepared according to Delaude et al. [3], yielding a material with an iron content was 86%. Other chemicals were of high purity and were used as received.

Degradation test

The absorb spectrum of ferrate solution and eosin solution was obtained with UV/vis spectroscopy. The concentration of ferrate solution was further determined by UV/vis spectroscopy at 510 nm where the solutions possess a maximum absorbance. The relations between absorbance and concentration has been detailed described in Ref [2].

The eosin solutions were prepared by dissolving eosin samples into distilled water. The effect of pH, temperature and amount of ferrate solutions to the was investigated. The pH value of the sample was adjusted by adding diluted sulphuric acid. After a certain reaction time, excess sodium sulfite solution was added to the reaction solution. Because the sodium sulphite is a strong reducing agent, the excess ferrate in the solution will be reduced by the sodium sulphite. Otherwise, the remaining ferrate solution will affect the determination of the concentration of eosin. Because their maximum absorption wavelength is relatively close to each other. Then by measuring the absorbance of the solution, the content of eosin in solution was determined.

Results and discussions

As shown in Figure 1, the UV-vis curve is the absorption spectrum of the eosin solution. At 515nm, there is a maximum absorption peak. According to the literature, the absorption peak was assigned to the characteristic absorption peak of eosin, which can be used as a qualitative description of eosin solution. In the following discussion, all the absorbance measurements were performed at this wavelength.

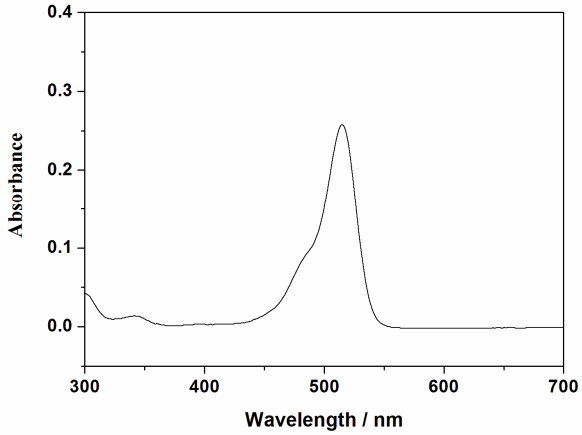

Fig.1 UV-vis spectrum of eosin solution

Figure 2 shows the effects of the ferrate amount to the eosin removal performance as a function of reaction time. As can be seen from the figure, regardless of the added ferrate amount, the reaction is carried out quickly. Within 2 minutes, the solution between eosin and ferrate has been reacted adequately. As the reaction time prolonged from 2 to 15 minutes, although the of removal eosin further increases, but the magnitude of the increase is very low. In addition, with the increasing amount of ferrate, the eosin removal rate increased steadily with the same reaction time. When adding 8mL ferrate solution into 50mL of the reaction solution, the eosin removal was up to 80%, indicating a strong removal performance of ferrate to eosin dye.

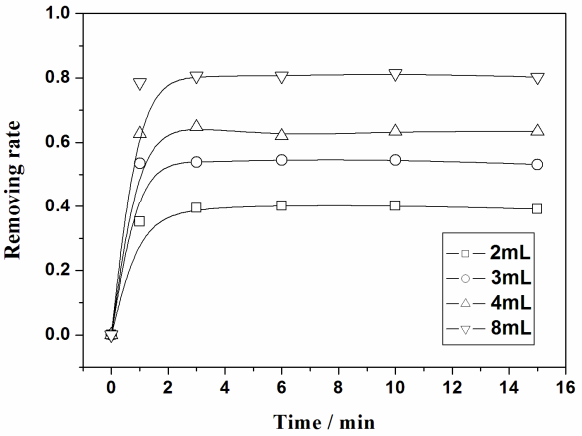

Fig.2 Fe (VI) amount effect to the eosin removal rate of Fe (VI) solutions

Figure 3 shows the effects of the solution pH on the removal performance of ferrate to eosin. As can be seen from the figure, with the decreasing of the pH value, eosin removal rate increased significantly. At the reaction time of 2 minutes, if the pH of the solution is 5, eosin removal rate can be 40%, and when the pH of the solution is reduced to 3, then the removal rate of eosin was up to 90%. This is mainly due to higher ferrate oxidation potential and thus the oxidation capability in acidic solution. According to the results reported in the literature, under acidic conditions, ferrate possesses the highest oxidation potential as we known. While under alkaline conditions, the oxidation potential reduced to 0.72V. Thus, reducing the pH is a good method to improve the ferrate oxidation property.

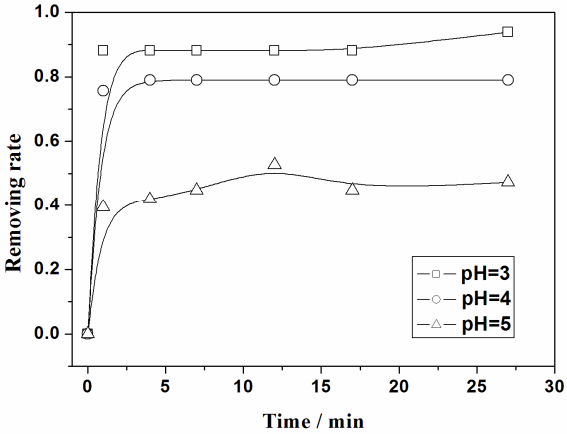

Fig.3 pH value effect to the eosin removal rate of Fe (VI) solutions

Figure 4 is the effect of reaction temperature on the removal of eosin. As can be seen from the figure, at the temperature range from 20 degrees to 50 degrees, the effect of temperature on the reaction is not very notable. Generally, the reaction speed will accelerate as the reaction temperature increases. However, due to the degradation of the ferrate as the temperature rises, the concentration of the ferrate solutions reduces resulting in the oxidation capability decrease. Especially under conditions of 50 degrees, it can be seen clearly from the figure that as the reaction time extended, the removal performance of ferrate to eosin decreases. For one hand, ferrate is unstable at high temperatures, it will degrade partly. For the other hand, the solution evaporated seriously at high temperature, resulting in the concentration of eosin solution raising.

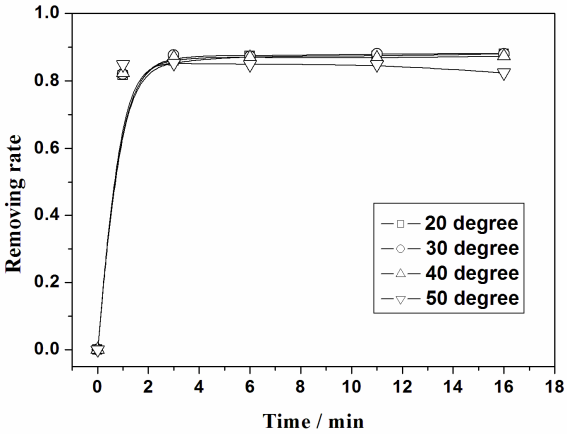

Fig.4 Reaction temperature effect to the eosin removal rate of Fe (VI) solutions

Conclusions

This paper studies the oxidation removal effects of ferrate towards eosin dye. The study found that with the increasing amount of ferrate, eosin removal steadily improved. Lowering the pH of the reaction system, the oxidation ability of ferrate can significantly improved, so that eosin removal increases. The effect of reaction temperature on the removal of eosin was not significant, mainly due to the temperature rise associated with the evaporation of solution and the degradation of ferrate solution. In short, ferrate is an excellent water treatment agent, which can be used to effectively remove dyes in the wastewater.

Keywords: Calcium hydroxide concentration; Pore solution; Strength; Stabilized soils

Abstract. Under the same cement content, the stabilized soils, made of the soils with similar physical properties, may be significant difference in the strength. In this research, three groups of soils were selected, and the soils in each group are similar in physical properties. Strength and ions concentration in pore solution of the stabilized soils were investigated. The result reveals that calcium hydroxide (CH) concentration in pore solution of the stabilized soils might not reach to saturation due to soil consuming Ca^{2+} and thus cause calcium silicate hydrates gels (C-S-H) and calcium aluminates hydrates gels (C-A-H) to form less. The cementitious hydrates are the main strength contributors of the stabilized soils. The Strengths of stabilized soils, the soils bearing similar physical properties, were almost identical as long as the CH concentrations in pore solution were saturated. The effect of chemical factors of soil on the strength of stabilized soil can be briefly attributed to the change of CH concentration in pore solution, and be further attributed to the influence of CH concentration on the amount of C-S-H and C-A-H formed in stabilized soils.

Introduction

Cement based stabilizer (Portland cement or that composed mainly from Portland cement) is well-established technique in subgrade stabilization [1-5]. Stabilized soils, under the same cement content, which are composed of the stabilizer and the soils bearing similar physical properties, exhibit significant differences in strength, even the strength of stabilized soils made of the soil with better physical properties is lower than that of the one made of the soil with worse physical properties [2,6]. Obviously, there must be some other factors that affect the strength of stabilized soils except for physical properties of soil.

After cement is mixed with clay, cement hydration mainly produces CH, C-S-H and C-A-H, and Ca^{2+} provided by CH is absorbed by soil until reaching saturation point, then pozzolanic reaction happens between the remaining CH and silica and alumina dissolved from the clay lattice to form additional cementitious material (C-S-H and C-A-H)[7,8]. The strength differences in stabilized soils are decided by the amount of hydrates produced by the pozzolanic reaction, the more CH participate in the pozzolanic reaction, the more hydrates are formed, and the higher strength of stabilized soil is obtained. However, the investigation cannot satisfactorily explain that soils bearing similar physical properties are significant difference in the strength of stabilized soil in the same cement content.

Cement can normally hydrate in different clay types, while the clays are different in the absorption amount of Ca^{2+} [9]. The soil is composed of kaolinite and illite, consuming less Ca^{2+} than that is composed of montmorillonite, therefore the strength of the stabilized soil is higher [10]. Additionally, other cations in soils, like Na^{+} and K^{+}, exchange with Ca^{2+} come from cement hydration, the more cation exchange capacity (CEC) of soils are, the lower strength of stabilized soils are obtained, and vice versa [11-14]. If organism in soil absorbs Ca^{2+} to exceed a certain degree, then the stabilized soils will not obtain adequate strength [15, 16]. It was reported that CH in stabilized soils might not be saturated, under the conditions, the soil further absorbing Ca^{2+} from cement hydrates would decrease the amount of cemetitious hydrates produced by the reaction between CH and soil, such as C-S-H and C-A-H etc., therefore, the same amount cement might not

produce the same amount of hydrates and obtain the same strength in the stabilized soils that were made of similar physical properties [6]. Nevertheless, the investigation does not provide enough proofs; moreover, it is still unclear the effect of chemical factors of the soils on the hydrates growing and compressive strength.

Test results

The specimens were made by mixing the soils (BT, TT2, WT, TT1, NT and GT) and different cement content (aw, aw=6, 8, 10, 12, 15, 18, 20, 22, 25, 28 and 30% of wet soil weight), and the specimens were named as BS, TS2, WS, TS1, NS and GS correspondingly. Relationship between the unconfined compressive strength of specimens (qu) and aw are shown in Fig.1, which reveals that qu increases slowly, as aw increases, until aw reaches the turning point indicated with arrow in Fig. 1 (named aw′), then the increment of qu produced by unit cement content increases obviously. As can be seen in Fig.1, although the soils with similar physical properties were mixed with equal cement content, the corresponding stabilized soils indicate significant differences in strength. Fig.1(a) indicates when BT and TT2 are both mixed with the same cement content (aw = 15 %), the strength of BS is one time higher than that of TS2, as aw＜aw′ , the strength increment of BS and TS2 produced by unit cement content are different, while aw＞aw′ , that of the two stabilized soils become almost identical. The similar phenomena are observed in Fig.1 (b) and Fig.1 (c).

Specimens were selected from each series of stabilized soils and were stabilized with three cement contents that were changed around aw′ , (as seen in Fig. 1, the aw′ of BS is 12%, and that of TS2, TS1, WS, NS and GS are 15%, 15%, 18%, 20% and 8%, respectively). Pore solutions

of the specimens were extracted, and pore solution's analysis are shown in Table 1, in each series, the pH and the concentration of OH^-, K^+ and Na^+ increase as cement content increasing, while the concentration of Ca^{2+} gradually reduces. Other ions concentration, such as Al^{3+}, SO_4^{2-} and SiO_4^{4-}, irregularly change.

The strength of BS is higher than that of TS2 under the same cement content, as shown in Fig.1(a), correspondingly, the pH and concentration of OH^-, K^+ and Na^+ of BS are higher than that of TS2, while the concentration of Ca^{2+} of BS is lower than that of TS2, as shown in Table 1. The similar phenomena can be observed from TS1 and WS, GS and NS in Fig.1 and Table 1.

The soils bearing similar physical properties may be different in chemical properties, such as cation exchange capacity and pozzolanic reactive ability, thus their Ca^{2+} consumption ability are different, which causes the amount of C-S-H and C-A-H produced in the stabilized soils to be different and thus produces different strengths of the stabilized soils, as the same cement content is added. For example, pH of BT is higher than that of TT2 (as shown in Table 1), thus CH concentration in pore solution of BS is higher than that of TS2 at equal cement content, and the strength of BS is higher than that of TS2. Similarly, although TT1 and WT are homogeneous in pH, cation exchange capacity and the amount of available silicon and alumina of WT are much higher than those of TTI, therefore CH concentration in pore solution of TS1 is higher than that of WS at equal cement content, and the amount of C-S-H and strength of TS1 are higher than that of WS. If sufficient cement is added to stabilize soils with similar physical properties, its hydration will produce enough CH to ensure CH saturated in pore solution of the stabilized soils. Under such conditions, soil consuming Ca^{2+} may only reduce the amount of CH instead of the amount of C-S-H; therefore, equal cement content could produce the same amount of C-S-H, and achieve the same strength of the stabilized soils. Fig. 1 shows that the strength increasing rates of specimens in each group are almost identical after cement content exceeding aw′ (CH saturation point of the stabilized soils). Specially, as shown in Fig.4, the specimens, treated to the CH saturated point, their strength increasing rules of stabilized soils in each group do represent the homogeneous strength development tendency.

Above results reveal an important fact, although there are many chemical factors affecting the strength of stabilized soils, which are different in different soils, the influences of different chemical factors on the strength of stabilized soils can be attributed to the influence on CH concentration in stabilized soils, and further be attributed to the influence of the CH concentration on the amount of C-S-H and C-A-H. Therefore, the adverse effects of different chemical factors of soils can be counteracted by increasing the CH concentration of stabilized soils.

Conclusions

1. Under the influence of physical and chemical factors of soil, soil may consume a lot of Ca^{2+} produced by stabilizer, which results in CH concentrations in pore solution of stabilized soils are under saturated. Thus the amount of C-S-H and C-A-H become less. The soils bearing similar physical properties may be significantly different in Ca^{2+} consumption, consequently, the amount of C-S-H and C-A-H generated by equal amount of cement may also have great difference, which causes the great difference in the strength of stabilized soils.;2. As long as CH concentration in pore solution of stabilized soils is saturated, C-S-H and C-A-H may normally form, as a result, equal amount of cement may produce equal amount of hydrates, and make the stabilized soils made of the soils bearing similar physical properties obtain the same strength.;3. CH concentrations in pore solution of the stabilized soils represent significant differences for the soils are very different in chemical factors, such as CEC and pozzolanic reaction, which lead to the variation in the consuming amount of Ca^{2+} provided by cement hydration and the formation amount of cementitious materials, like C-S-H and C-A-H.

Keywords: screw separator; development; application

Abstract. This article describes the research and development with the international advanced level of the screw separator, mainly used for the cleaner tailings fiber and the wastewater recycling and the use of stand-alone concentrated effect, into the plasma concentration of more than 0.5%, themaximum slurry concentration up to 60%, the device uses a unique control mechanism, without the power consumption will be able to achieve the automatic control of the plasma concentration, can efficiently remove moisture, recycled fiber, conservation of resources.

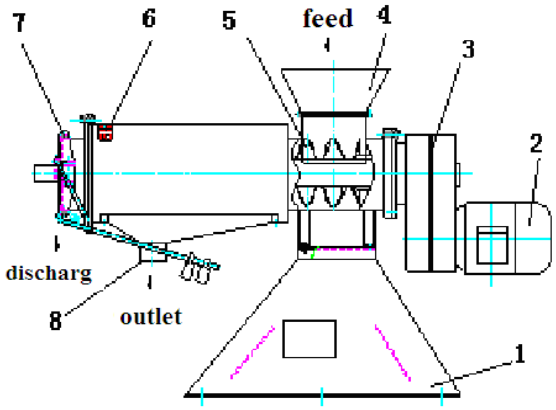
1Overview

In pulping process,it will produce a certain amount of waste residue, also known as tailings. The tailings contain a large number of moisture content and fiber. Now, stacked tailings of many enterprises are in the outdoor. Severe pollution caused by a lot of stacked tailings, which don't do process.Loss of water and fiber caused great waste to the enterprise. To draw lessons from foreign advanced technology, it will design and develop the screw separator with advanced level at home and abroad, mainly used for the cleaner tailings fiber and the wastewater recycling. The current domestic pulp manufacturers don't do process tailings, direct discharge away, which is no processing equipment. So the development of the screw separator will fill the domestic blank.

2 Introduction of the equipment

2.1 Structure

As shown in figure 1, the machine is made up of feeding mouth, motor, reducer, rack, filter drum, screw axis, automatic discharging export control mechanism, wastewater, etc. Contact with the plasma, the liquid parts adopt stainless steel manufacturing.



1-frame; 2- motor; 3-reducer; 4-feeding mechanism; 5-screw spindle; 6-filter drum; 7-discharging control mechanism; 8-outlet

Fig.1. Results structure of the screw separator

(1)Rack

Frame is composed of steel and steel plate welding. The frame is the matrix of the equipment, so it is the main supporting role. According to the 3 d model for the stress analysis of the whole machine to determine the center of gravity of the machine parts, and then designs as shown in the frame structure, ensure the stability and reliability of the equipment work.

(2)Screw Axis

Spiral shaft is composed of spiral pipe and spiral blade, the shaft top, which is all made of stainless steel materials. Equal pitch of the helical blade, and it is such as diameter, pulp from into pulp after entering the spiral filter press, box through the rotation of the screw axis, driven pulp movement forward. At the same time the pulp is for extrusion, and dehydration.

Screw axis and the connecting way of reducer is straight plug-in, which reduces intermediate links, ensures the installation precision and improves the transmission efficiency.

(3)The Filter Drum

Water drum filter consists of flange, filter plate, steel plate, such as stainless steel welded together. The pressure of the filter drum gradually increase from the inlet to the discharging mouth, so the center of the filter drum flange changed gradually from the beginning to the end. Screw axis of slurry squeezing out water drums filter after dehydration, drum filter using slotted screen.The size of the gap according to the concentration of the slurry, generally from 0.2 mm to 0.2 mm.

(4)Part of the Control

Control part consists of discharging plate, connecting rod, a heavy hammer, chain plate, pin, etc, is a special kind of linkage. Through the gravity of the hammer, to adjust the opening degree of discharging plate, the plate opening is smaller, the greater the pressure of the pulp, the smaller the slurry concentration. On discharging plate opening, the greater the pulp you less pressure, the slurry concentration. according to the concentration of slurry to adjust heavy hammer position, to control the pulp out of the slurry concentration[1].

(5)Device of the Transmission

Transmission device is to choose the structure of motor and speed reducer. The compact structure, transmission cumulative error is small and little vibration. At the same time installation space is small and saves the area.

2.2 The main technical parameters

Model: SP260, into the slurry concentration above 0.5%; The plasma concentration of 30%~60%; Production capacity is 6~8 $t \cdot d^{-1}$; Screw specifications phi 260 mm; Screw speed 50 $r \cdot min^{-1}$; The motor power 7.5 kw; Overall dimensions1720mm×660 mm×1900 mm; Equipment weight 550 kg.

2.3 The Principle of Work

As shown in figure 1, screw press filter consists of inlet, motor, reducer, rack, filter drum, screw axis, automatic discharge control mechanism, and other components of the waste water outlet, separation, dehydration, filtering, and the integrated use of extrusion technology. Feed concentration for more than 0.5%, according to the different of a slurry of plasma concentration can reach 60%, the highest realizes one machine can, is the present domestic very advanced solid-liquid separation equipment, can be used for the separation of a variety of materials, such as fiber, plastic, minerals, sludge, etc., mainly used for pulp and paper, sewage treatment, agriculture, food industry, such as domain, application scope is very broad.

Tailings from the slag separator into the screw pressure filter, screws spindle drive tailings with spiral blade forward movement and distribution on the axis of the auger spiral blade has a certain compression ratio. At the same time it improves the pressure of the front, forcing the moisture in the material under the action of pressure and filter out filter drum, out of a drain. Work is continuous press filter, the material is pumped through the body, front mounting pressure, when the big to a certain degree, is to open discharge outlet, squeeze, achieve the goal of extruded material. In order to grasp discharging speed and water content, it can adjust the host at the bottom of the counter weight (weight), in order to achieve satisfaction proper discharge concentration[2].

2.4 Technical Characteristics

(1)Into the pulp concentration is 0.5% more than without preconcentration, thus saving the water resource;

(2)Can be used for the separation of various solid structure, such as fiber, plastic, minerals, etc.;

(3)Stand-alone generate solid dryness up to more than 60%, this is does not have the similar equipment at home, the highest domestic enrichment equipment stand-alone dryness in about 28% or so;

(4)After the separation of solid dryness can adjust;

(5)Even particle size less than screen hole, the particle can be filtered out;

(6)Easy to install, operate and maintain, the screw has self-cleaning function;

(7)The space is little, installation without operators;

(8)Low investment cost, operation cost is low;

(9)Screw press filter uses a special link mechanism, by weight of weight of pulp out of the automatic control of dryness, change of the paste extrusion, in order to obtain different degree of dry solid. The control mechanism without hydraulic, pneumatic control, don't need any energy consumption, saving power consumption. At the same time, the single machine to more machine can realize the function, truly a multi-usage, reduce the production cost, save the water;

(10)The device has the function of overload protection.

3 The Flow of Process

In waste-paper deinking production line, for example, its production process flow diagram for[3]:

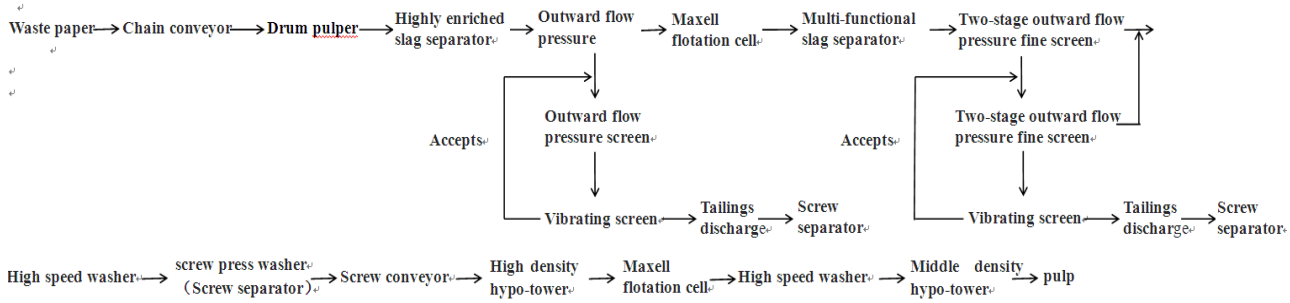


Fig.2. Waste-paper deinking production line flow chart

Can be seen from the above process, the spiral press filter installation is simple, which just puts the discharge of tailings to the screw press filter. In addition, the screw press filter can also be used in the mainstream line alternative helix crowded pulp machine, especially in non-wood fiber (cotton, bamboo, cotton, etc.) production line in the enrichment effect, which is better than spiral syrupcrowede confidential[3].

4 The Compare of Screw Press Filter and the Helix Crowded Pulp Machine

Helix crowded pulp machine is the wide application of an enrichment equipment, its different with spiral press filter is:

4.1 Screw press filter with helix crowded pulp machine are made of screw extrusion materials, action principle is the same. Due to the complex helix crowded pulp machine structure, big volume, heavy, the smallest screw phi 450 mm diameter, production capacity of 40 ~ 50 t/d, it is used in the mainstream line. Screw press filter for phi 260 mm diameter, production capacity of 6 ~ 8 t/d, apply to the tailings concentrated, mainly used in the end production line[4].

4.2 Screw press filter with helix crowded pulp machine control system is different. Four pneumatic cylinder helix crowded pulp machine by controlling the size of the discharging mouth to control discharge concentration. Pressure filter is established by the host at the bottom of the counter weight (weight) to control the pulp concentration. The position of the moving heavy

hammer, adjust the size of torque, control the discharging mouth opening degree and the extrusion pressure, reach the purpose of extruded materials, so as to control the size of the plasma concentration of[5].

5 Conclusion

Screw press filter of different pulp, pulp density is different, the cotton fiber, cotton stalk, and wood pulp pulping tailings for enrichment, the plasma concentration can reach 60%, even higher, to the tailings concentration, paper pulp slurry concentration can reach 30-40%. Screw press filter after successful development, the first in shandong gaomi paper mill trial, after more than half a year of operation practice proves that spiral press filter running effect is good. The tailings fiber and waste water recycling, saves a lot of resources for the enterprise, reduces the production cost, brings the good economic benefits. Now, the equipment has been concentrated in shandong JiaHe group compound fertilizer raw material used in production lines.

Next, we will develop a screw press filter series products, expand product specifications, to meet the market demand.

Add: three-dimensional figure spiral filter press

Key words: Hot corrosion; Laser shock processing; In718 superalloy

Abstract: The aim of this research is to improve the hot corrosion resistance of In718 superalloy by laser shock processing. Specimens were treated by laser shock processing on the whole surface. The hot corrosion resistance beneath molten Na_2SO_4 under 900 ℃ was investigated. The effects of laser shock processing impacts on residual stress, surface microstructure and microstructure after hot corrosion test were investigated. Results show that 3 times laser shock processing can induce -400 MPa compressive residual stress. The microstructure was characterized by highly tangled and dense dislocations and a large number of twins. The average corrosion rate of In718 superalloy treated by laser shock processing is about 50 % lower than that of the untreated superalloy.

Introduction

Laser shock processing (LSP) is one of the most important surface modification techniques. Due to the interaction between high power density (GW/cm^2) laser beams and the surface of alloys, a high pressure shock wave was generated. The high level pressure causes a strong plastic deformation on the surface, which leads to a compressive residual stresses of several hundred MPa [1]. And the grain is refined owing to the dynamic recrystallization. Meanwhile, a larger number of microstructure defects, such as dislocation and twins, are induced on the surface layer.

In718 superalloy has a good comprehensive mechanical property, hot corrosion resistance, and oxidation resistance in the medium microtherm. It is widely used in turbine engine, advanced ship engine. In recent years, many researches have been done on the improvement of alloy's mechanical properties and electrochemical corrosion resistance. J.Z. Lu et al. concluded that compressive residual stress and grain refinement during LSP improved the stress corrosion cracking (SCC) resistance [2]. C. H. Zhou et al. improved hot corrosion resistance of alloys by nano crystallized and the micro crystallized coating [3]. However, the hot corrosion behavior of alloys treated by LSP is rarely involved. This study is trying to figure out the LSP's effects on the hot corrosion resistance of In718 superalloy under 900℃.

Experiment

The alloy used in this experiment is In718 superalloy, whose chemical composition (wt.%) is: Cr-20, Mo-3.3, Al-0.5, Ti-0.75, Nb-5, Ni-55, C-0.05 and balanced Fe. The material was cut into rectangular specimens of 15 mm × 15 mm × 2 mm in size.

The LSP experiments were carried out by a Q switched Nd: glass high power laser. The residual stresses were tested by applying standard X-ray diffraction (XRD) techniques. Transmission electron microscope (TEM) was used to observe the microstructure of the laser treated layer.

The specimens treated by LSP and prepared salt were put into a large Al_2O_3 crucible, which was then placed in an chamber electric furnace under 900 ℃. All the specimens were surrounded by an atmosphere consisting of Na_2SO_4 molten salt and air at the test temperature for 20 hours. The initial and final weights of the specimens were measured to assess the corrosion level. The surface morphology was characterized by scanning electron microscope (SEM) equipped with energy dispersive spectrum (EDS). The phases were identified by X-ray diffraction (XRD).

Results

Specimens treated by LSP from 1 to 3 times maintained an average compressive residual stress of -280 MPa, -360 MPa and -400 MPa, respectively. High level compressive residual stresses maintained within 250 μm from the top surface. The cross section of the alloy was observed by metallurgical microscopy. Figure.1 shows the typical TEM images of the substructures effected by LSP in the top surface layer of In718 superalloy. Fig.1 (a) is the image of highly tangled and dense dislocation. Fig.1 (b) is a lager number of typical mechanical twins.

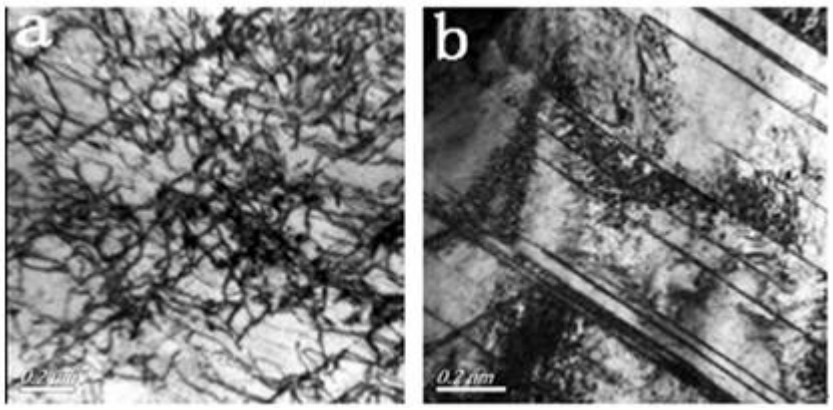

Fig.1. Typical substructure of the top surface after LSP

(a) dislocation (b) mechanical twins

As is shown in Fig.2, all of the specimens were layered to three layers after hot corrosion test. However, the depth of corrosion layers was quite different. From Fig.2 (a), specimens untreated by LSP have an corrosion depth about 30μm. The outer layer has been cracked and the grains were not homogeneous, its inner corrosion layer is very deep. The interface of oxidate film and substrate is wave shaped and has holes in it. While Fig.2 (b) shows specimens treated by 3 times LSP have an corrosion depth about 20μm. The corrosion layer has a good adherence with the substrate and the grains are tiny homogeneous. The interface is much smooth and has less holes. From the corresponding EDS of the inner layer, both of the specimens are rich of Cr in this exact layer.

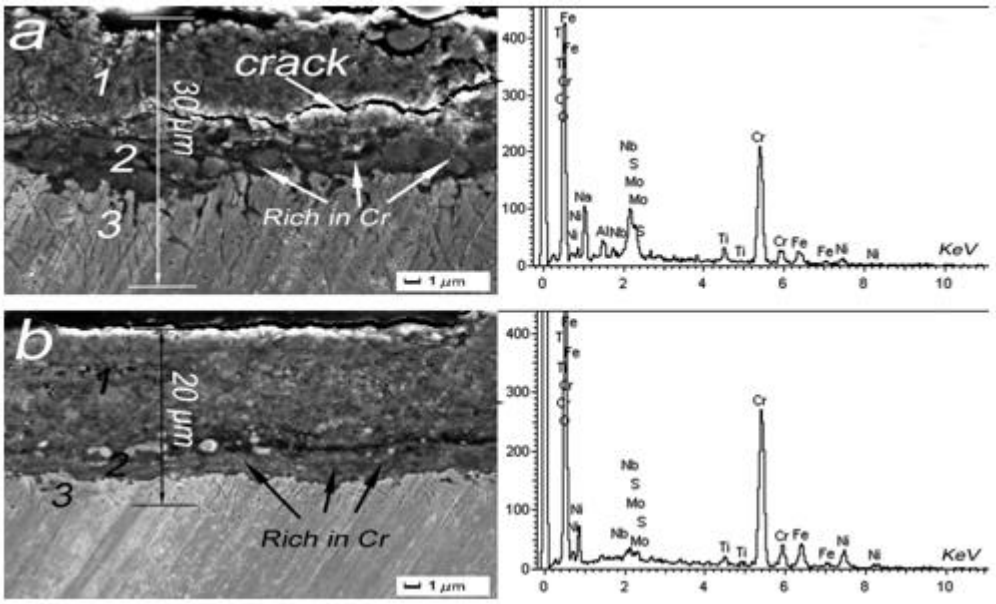

Fig.2. The section morphology of corrosion layers and their EDS of the inner layers

(a) specimen untreated by LSP (b) specimen treated by 3 times LSP

According to the phase analysis, the outer layer corrosion products are very complicated. The inner layer corrosion products mainly consist of (Cr, Fe)$_2O_3$, Fe(Cr,Al)$_2O_4$, NiCr$_2O_4$, Al$_2O_3$. The inner corrosion layer corrosion products mainly consist of (Cr, Fe)$_2O_3$, Al$_2O_3$. Normally, oxidates such as Cr$_2O_3$, Al$_2O_3$ grow slowly and have good stabilities at high temperature [4].

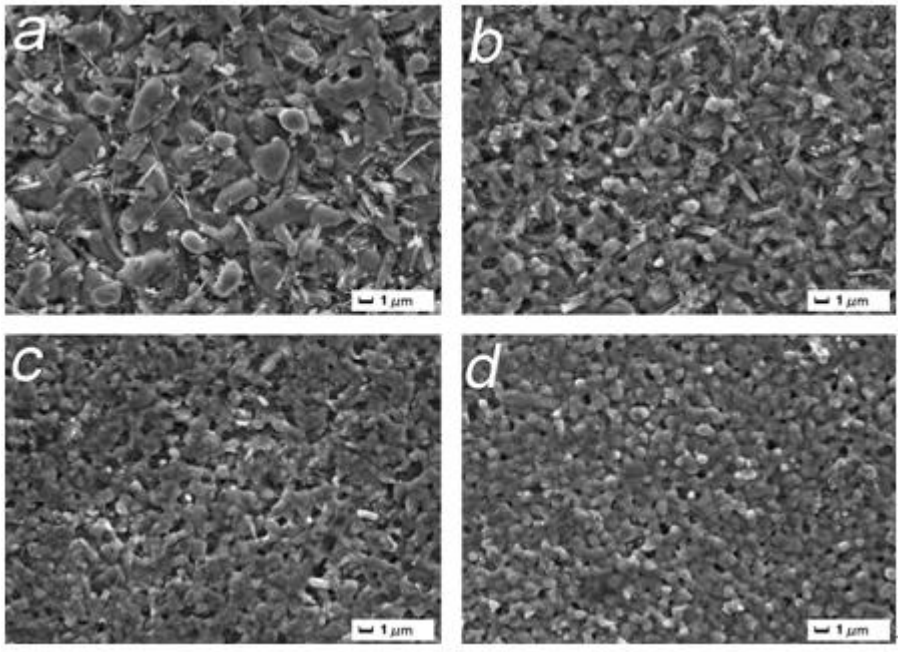

Fig.3. Hot corrosion morphology of In718 superalloy

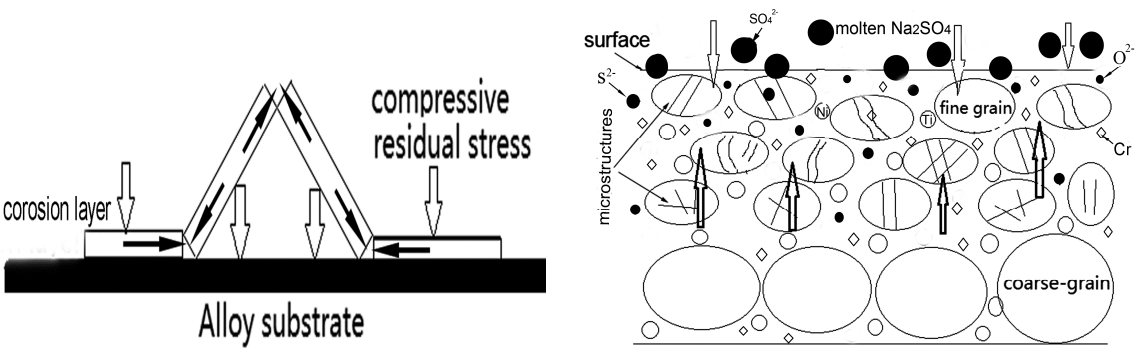
(a) 0 LSP, (b) 1 LSP, (c) 2 LSP, (d) 3 LSP

Fig.3. shows the hot corrosion morphology of In718 superalloy. With the increase of LSP times, the corrosion products turned to be tiny homogeneous, the continuity was getting better. Corrosion products of untreated specimens are several times bigger than those treated specimens. The tiny homogeneous corrosion products will be beneficial for the dispersion of the corrosion stress.

After corrosion in molten Na$_2$SO$_4$ for 20 h, the average corrosion rate of specimens untreated by LSP was 0.88 (mg/cm^2·h), while the average corrosion rate of specimens treated by 1 time LSP was 0.65 (mg/cm^2·h), which is 35.4 % lower. The average corrosion rate of specimens treated by 2 times LSP was 0.60 (mg/cm^2·h) , which is 46.7 % lower than that of the untreated specimens. And the average corrosion rate of specimens treated by 3 times LSP was 0.57 (mg/cm^2·h) , which is 54.4 % lower than that of the untreated specimens. Therefore, LSP has beneficial effects on the hot corrosion resistance of the In718 superalloy.

4. Discussion



(a) compressive residual stress effect (b) microstructure effect

Fig. 4. Schematic of the LSP effect on hot corrosion behavior

We have shown that the interaction between laser pulse and the surface of In718 superalloy could lead to a high level compressive residual stress in the surface and depth direction. There is serious stress corrosion in the hot corrosion test. As is shown in Fig.4 (a), compressive residual stress in the surface direction can delay crack initiation of the corrosion layer and compressive residual stress in the depth direction can slow down the growth of microcrack on the specimen surface [5].

According to the oxide film mass transfer experiments [6], dislocation and grain boundary diffusion was significantly faster than the lattice diffusion. As is shown in Fig.4 (b), in the corrosion process, these microstructures induced by LSP added the paths of element diffusion. Self-healing capability of the oxidation films was improved. Moreover, the nucleation energy reduced in the crystal defects, so oxidation film can be more easily nucleated in these places. The growth stress was released, which also makes a better adhesion with the alloy substrate.

5. Conclusions

The following conclusions can be drawn from this research:

1) With the increase of laser shock times, the corrosion lightened. After corrosion for 20 h at 900 ℃, the average corrosion rate of In718 superalloy treated by laser shock processing was about 50 % lower than that of the untreated superalloy.

2) The grain refinement and microstructures in it add the element (Cr, Ti etc.) diffusion paths. Self-healing capability of the oxidation films were improved. The tiny homogeneous oxidation layer with a good plasticity was formed in a short time. The high level compressive residual stress in the LSP treated layer can increase the adhesion of the corrosion layer. It works for the balance of the corrosion stress.

Extraction and Purification of Fluorene from Wash Oil

Yongsheng E

Department of Biomedical and Chemical Engineering, Liaoning Institute of Science and Technology, Benxi Liaoning, 117022, China

email: eys73@126.com

Keywords: Fluorene; Extraction; Purification

Abstract: Fluorene is a basic chemical raw material, which has wide applications.This paper introduces the current fluorene technology of extration and purification from wash oil. Use the after-cut of wash oil as raw material, get fluorene by distillation and solvent crystallization. The content of fluorene is higher than 97%.The total yield is 72.24%, which is higher than current domestic production levels.

1 Introduction

Fluorene is a basic chemical raw material, which is mainly used for preparation of medicines, synthesizing dyes and accessory ingredients etc. It is really worthwhile expanding the market[1].

The production methods of fluorene are divided into two kinds of synthesis and extraction in general. Due to the high cost and serious pollution of synthesis, all fluorene products are extracted from coal tar[2]. Fluorene are mainly distributed in the wash oil of coal tar, the mass fraction is about 10%. The study about extraction and purification of fluorene from the wash oil has important significance.

Extraction and purification of fluorene from wash oil have cooling crystallization method and solvent crystallization method[3]. Cooling crystallization method is through cooling fluorene fractions and crystallizing without solvent, the concent of fluorene product is 85%. Solvent crystallization method is through adding solvent in the crystallization process, thus the concent is higher than 95%[4]. Because fluorene product has high purity and good quality by solvent crystallization method, thus it becomes the main method for producing fluorene[5]. This paper will do detailed study to solvent crystallization method.

2 Experiment

2.1 raw material

The after-cut of wash oil, the composition are shown in Table 1

Table 1 Composition of the after-cut

Component	*acenaphthene*	*diphenylene oxide*	*fluorene*	**others**
Content [%]	15	30	38	17

2.2 The experimental equipment

Efficient distillation column, φ100 × 2500, triangular spiral filler, the number of measured plate is 85.

A crystallization device.

The results are analyzed by a gas chromatograph.

2.3 The experimental procedure

Take the after-cut of wash oil 40kg, which is distillated in the distillation column of plate number 85. When the reflux ratio is 5:1, 10:1 or 15:1, we cut a fraction every 2-3℃, test its purity and calculate yield. According to the results, we choose suitable distillation rang and reflux ratio.

Use ethanol, toluene or xylene to purify fluorene fractions above by crystallization. Change solvent ratios and crystallization temperature to observe the changes in quality and yield of fluorene. We require the content of fluorene products is more than 97%.

3 Results and discussion

3.1 the distillation of after-cut

Take the after-cut of wash oil 40kg, distill, the experimental results are shown in Table 2.

Table 2 The experimental results of distilling the after-cut

Serial Number	Distillation Range [℃]	Reflux Ratio	Weight [kg]	Content [%]	Fractions species
1	280-283		3.4	25.4	Before-cut
2	283-285		4.2	39.92	Main distillate fraction
3	285-287		5.12	59.15	Main distillate fraction
4	287-290	5：1	4.56	66.76	Main distillate fraction
5	290-292		4.7	65.59	Main distillate fraction
6	292-294		2.5	58.32	Main distillate fraction
7	294-297		3.2	35.35	After-cut
8	283-285		5	44.29	Main distillate fraction
9	285-287		5.52	65.51	Main distillate fraction
10	287-290	10：1	4.16	71.81	Main distillate fraction
11	290-292		4	70.95	Main distillate fraction
12	292-294		3.2	64.15	Main distillate fraction
13	294-297		2.4	38.21	After-cut
14	283-285		4.47	45.37	Main distillate fraction
15	285-287		5.26	65.67	Main distillate fraction
16	287-290	15：1	4.7	72.02	Main distillate fraction
17	290-292		4.5	71.39	Main distillate fraction
18	292-294		3.2	63.66	Main distillate fraction

It can be seen from the experimental results, the content and quantity of fluorene fractions are different with the different reflux ratio and distillation range. The suitable distillation range is 283℃ ~ 294℃.

These main distillate fractions every reflux ratio are mixed, we will obtain the entire quantity of fluorene fractions, and may calculate the yield and content of the main distillate fraction every reflux ratio. The results are shown in Table 3.

Table 3 The results of the mixed main distillate fractions

Serial Number	Distillation Range [℃]	Reflux Ratio	Weight [kg]	Content [%]	Yield(%)
1	283-294	5：1	21.08	58.30	80.85
2	283-294	10：1	21.88	62.65	90.18
3	283-294	15：1	22.13	63.79	92.87

It can be seen from table 3, the weight, content and yield of fluorene fractions are different with the different reflux ratio. When the reflux ratio is 5:1, the producing speed increases and energy consumption reduces, but the content and yield are low. When the reflux ratio is 15:1, the content and yield of flourene fractions are high, but the production efficiency is low and energy consumption becomes large. We should comprehensively consider these factors, choose appropriate reflux ratio. According to the above results, we select the reflux ratio of 10:1, thus, we can get the flourene fractions, its content is 62.5% and its yield is up to 90.18%.

3.2 the solvent crystallization of flourene fractions

Take flourene fractions above, its content is 62.5%, crystallize with different solvent, the experimental results are shown in Table 4.

Table 4 The experimental results of solvent crystallization

Serial Number	Solvent Species	Solvent and fraction ratio	Crystallization Temperature (℃)	Content [%]	Yield [%]
1	ethanol	0.8：1	25	88.15	84.51
2	toluene	0.6：1	25	92.47	80.21
3	toluene	0.8：1	25	95.26	78.54
4	toluene	1：1	25	96.38	74.28
5	xylene	0.6：1	25	94.21	81.25
6	xylene	0.8：1	25	97.45	80.11
7	xylene	1：1	25	97.89	75.69
8	xylene	0.8：1	20	93.84	83.57
9	xylene	0.8：1	23	95.73	81.49
10	xylene	0.8：1	28	97.69	76.38
11	xylene	0.8：1	30	97.92	73.24

It can be seen from the experimental results, due to poor solubility, ethanol is not suitable as the crystallization solvent of fluorene fractions. In the same amount of solvent and crystallization temperature conditions, the yield and quality using xylene as solvent is better than using toluene, therefore, we choose xylene as crystallization solvent of fluorene fractions.

It can also be seen from Table 4, a large proportion of the solvent and a high crystallization temperature will improve the quality of fluorene, but the yield is low. On the contrary, a small proportion of the solvent and a low crystallization temperature will increase yield of fluorene, but the quality is poor.

According to the results shown in Table 4, we select the solvent and fluorene fractions ratio of 0.8:1, the crystallization temperature of 25℃, which are more suitable crystallization conditions. Thus, we can get fluorene product whose content is 97.45% and yield is 80.11%.

The total yield of two steps is 72.24%.

4 Conclusion

4.1 First, the after-cut of wash oil is distillated in the distillation column of plate number 85, the reflux ratio is 10:1, the range of distillate temperature is between 283 ℃ and 294 ℃. The content of fluorene fractions is 62.65% and the yield is 90.18%.

4.2 Second, use xylene as solvent to purify fluorene fractions. The solvent and fluorene fractions ratio is 0.8:1, the crystallization temperature is 25℃, content is 97.45% and yield is 80.11%. The total yield of two steps is 72.24%.

Keywords: Microwave-hydrothermal method; synthesis; Indium oxide; nanopowder.

Abstract: In_2O_3 nanopowder was successfully synthesized using microwave-hydrothermal method; by a very simple fast reaction between $InCl_3$ and urea in aqueous solution contain 1% polyethylene glycol. The products were characterized by the techniques of X-ray diffraction (XRD), Scanning electron microscope (SEM) and Fluorescent spectrum. The result shows that as-prepared In_2O_3 nanopowder is cubic phase, the morphology is square composed of many particles.

1 Introduction

In_2O_3 is an important functional material which has a wide band gap, small resistivity and high catalytic activity. It is a kind of n-type semiconductor. Because In_2O_3 material has showed good gas-sensing properties for oxidizing and reducing gases, and is widely used in gas sensors[1].

Indium oxide and indium hydroxide is important semiconductor material, the block In_2O_3 has no fluorescence properties at room temperature. However, when the size reduced to the nanoscale, as a result of the existence of crystal aerobic hole, it has good fluorescence properties. The direct band gap width of In_2O_3 is 3.6 eV, indirect band gap is 2.6 eV, In_2O_3 is a kind of wide band gap transparent semiconductor materials. Bulk phase indium oxide is a larger third-order nonlinear vibration of non-oblique inorganic materials, But when the particle size decreases, especially after nanoparticlization, as nanoparticles have larger surface area. There are a large number of atoms, or ions in particle surface show that the larger surface activity, so they are sensitive to the external environment[2]. By changing the environment around the particles, the optical properties of the particles will have great changes. There have been many past literature reported In_2O_3 nanostructures with good photoluminescence properties. For example, Yang etc found that the emission wavelength of In_2O_3 nanosphere and nanoclusters is 416 nm and 439 nm. Zhang etc reported indium oxide nanoparticles under UV irradiation has distinct emission peaks at 480 nm and 520 nm[3]. Qian etc found that the emission wavelength of In_2O_3 nanocubes is 378 nm, 378 nm, 420 nm, and the emission wavelength of In_2O_3 nanofibers is 450 nm.

The nanometerIn_2O_3 is a new type of inorganic materials, which is applied widely. Due to the fine particle size of particles, nanometer materials produced surface effect, quantum size effect, small size effect and macroscopic quantum tunneling effect what bulk material does not have. Because the nanometer indium oxide has many excellent properties, the preparation of nanometer In_2O_3 becomes one of the hot research in China in recent years [4] .

In this paper, nanometer In_2O_3 was synthesized using Microwave-hydrothermal method. It was characterized by the techniques of X-ray diffraction (XRD), and a preliminary discussion of the formation mechanism of indium oxide particles.

2 Experimental section

2.1 Instruments and reagents

Chempower microwave synthesizer（Zhichun, Shanghai Scientific Instrument Co.,Ltd) was used. Powder XRD was used to characterize the sample. Data were collected on a Rigaku

D/max-2500V/PC X-ray diffractometer(Japan). The morphology and size were determined by SEM. The SEM images were recorded on a Quanta 200 FEG field emission scanning electron microscopy (USA). Cary Eclipse fluorescence spectrometer(USA Varian Company) was used for monitoring the fluorescent spectrum of as-prepared sample.

All the reagents used were of analytical purity. Doubly distilled water was used throughout the experiments.

2.2 Synthesis of In_2O_3 nanopowder

Put 0.3g $InCl_3$ and 0.4g urea in the microwave hydrothermal reaction bottle, 10mL 1%PEG solution was added, sealed bottle and put it in the microwave reaction apparatus. At 120 ℃, microwave reactor 180 minutes. When the reaction was ended and cool down naturally to the room temperature. Then the precipitate was centrifuged, washed with the distilled water and dried at 60 ℃ in the vacuum for 4 h, the power was sintered at 773 K for 2 h. The final product was collected for the characterization.

3. Results and discussion

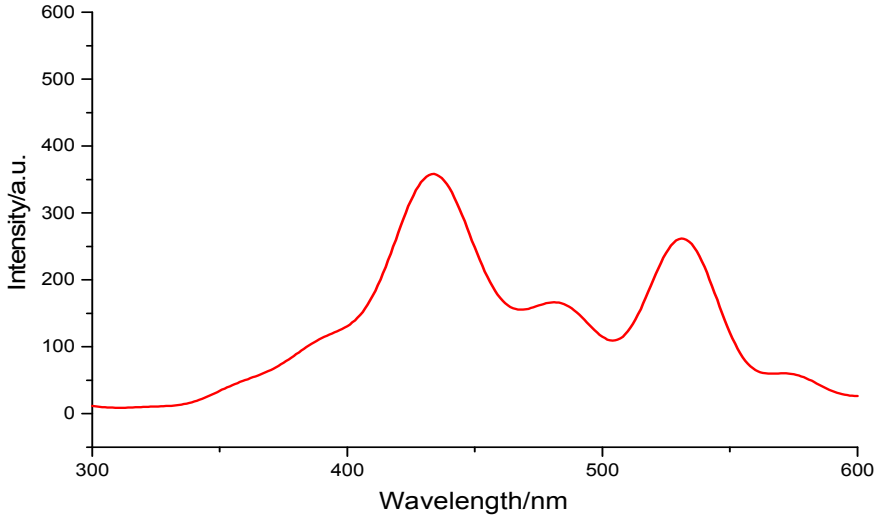

Fig.1 Fluorescent spectrums of sample

Figure 1 shows that at 435 nm and 530 nm, samples have strong fluorescence emission. Known by the SEM image, the product is a cubic structure. the block In_2O_3 has no luminescent properties. And different methods for preparing nanometer In_2O_3 particles have different emission spectra. Indicating their photoluminescence properties may be affected by the dimensions, shape and size. Compared with the literature [2], the strongest absorption peak of the sample is 435nm, slightly red shifted.

Figure 2 is a scanning electron micrograph of the sample. It is evident from the figure that sample particle is tetragonal structure, and its shape is very regular, angular. Because of reunion, some part seems to be the large square.

Fig.3 is the X-ray diffraction patterns of as-prepared samples. The result shows that In_2O_3 product is cubic structure. The intensity of the diffraction peak is higher declares that product has good crystallinity.

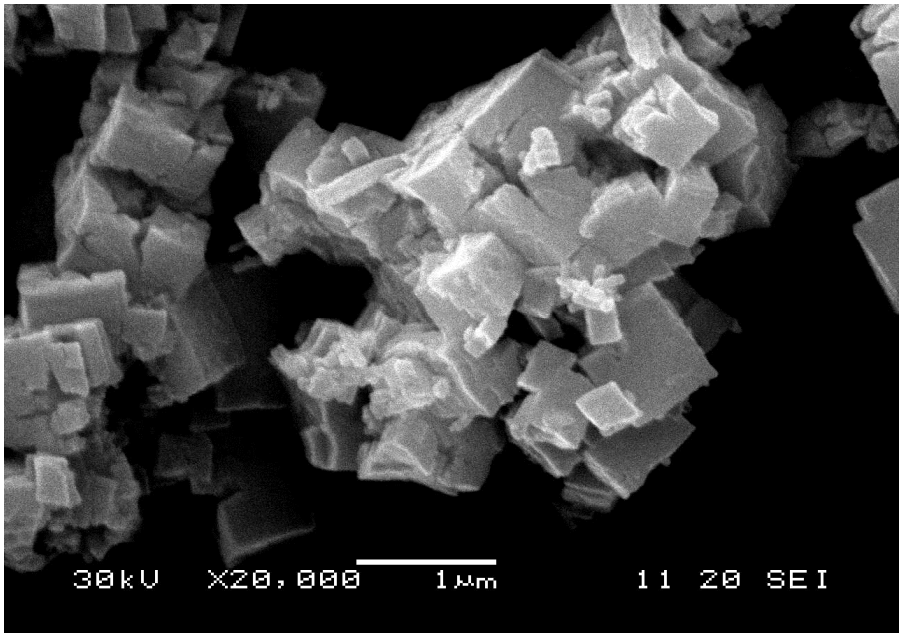

Fig.2 Scanning electron micrograph of as-prepared sample

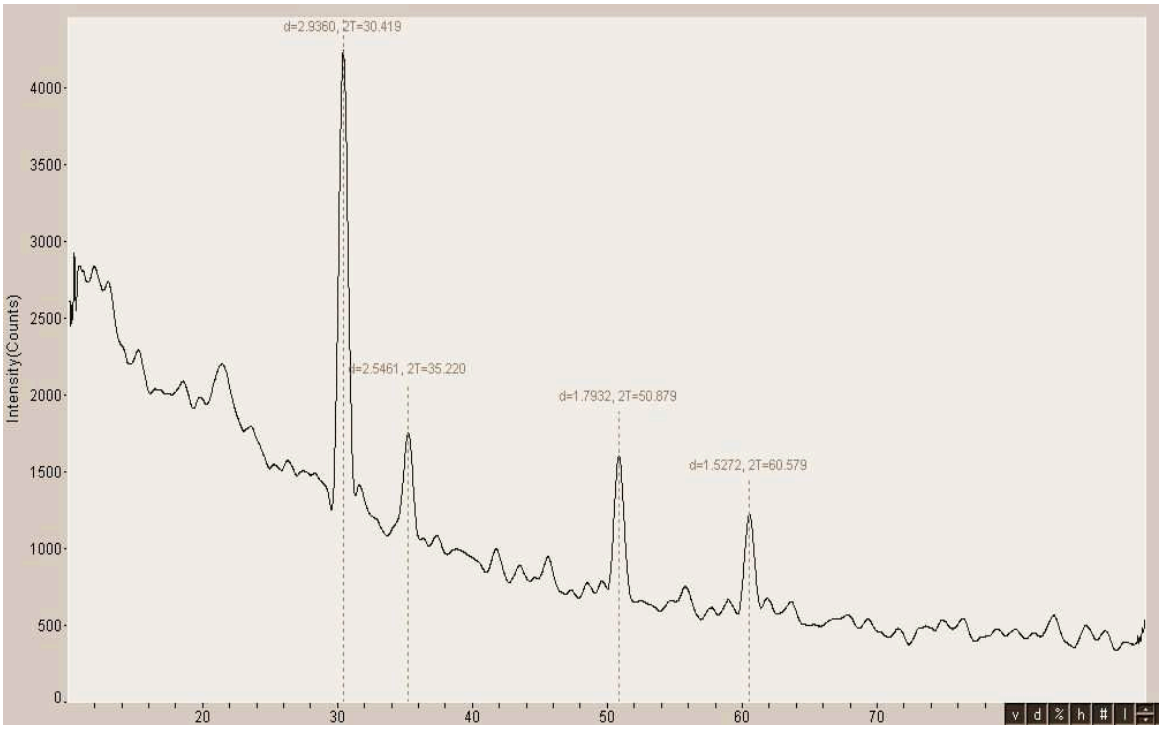

Fig.3 The X-ray diffraction patterns of as-prepared samples

Under the condition of microwave reaction, $InCl_3$ releases In^{3+} which combines with OH^- which urea releases. Producing predecessor $In(OH)_3$. PEG in the reaction is a surface active agent, serving as dispersion. Precursor decomposes at a high temperature, to produce In_2O_3 pale yellow powder.

$$In^{3+} + OH^- \rightarrow In(OH)_3$$

$$In(OH)_3 \rightarrow In_2O_3 + H_2O$$

In the process, the influence of the temperature may be reflected in two aspects. Firstly, under the high temperature calcination, due to the loss of lattice oxygen, indium oxide can form the stoichiometric oxide. Indium oxide bulk phase produces oxygen vacancy and free electrons. In the process of gas sensitive response, is a important factor to affect gas sensitive performance. Secondly, the calcination temperature is different, the size and the crystallisation degree of In_2O_3 will be affected [5].

4 Conclusions

Under the microwave hydrothermal conditions, white fine powder $In(OH)_3$ was prepared by $InCl_3$ and urea in PEG aqueous solution. Unde the high temperature calcination, the predecessor decomposed, producing In_2O_3 light yellow crystal. The shape is more regular, and is tetragonal structure. There was a strong fluorescence emission at 435 nm and 530 nm, compared with the literature, slightly red shifted.

Acknowledgments: This work is supported by Functional Materials Research Team of Huanggang Normal University.

Key words: Phosphogypsum; Softening coefficient；Balling; Cement coating;Small hollow block

Abstract. The non-calcined phosphogypsum was modified and purified by quicklime, aged, treated by balling and cement coating, and then mixed with an appropriate amount of water, the cementitious material, gravel and so on. After using the vibration pressure molding process and the nature curing, the prepared high-strength and water-resistant phosphogypsum small hollow block can produce a softening coefficient of 0.82 and a compressive strength of 7.5 MPa, and the other properties meet the MU7.5 grade requirements of normal concrete small hollow block on the GB 8239-1997, which broadens the application range of phosphogypsum small hollow block, and may provide a new way to solve the comprehensive utilization of phosphogypsum.

Introduction

Phosphogypsum is industrial byproducts of phosphoric acid production process emission, and producing of 1t phosphoric acid will discharge about 5t phosphogypsum. With industrial development, China has accumulated stockpiles of several gigatons phosphogypsum, and the annual phosphogypsum emissions have more than 50 million tons, but its utilization rate is only 20%. Phosphorus chemical phosphogypsum piles up like a mountain, encroaches the fertile land, pollutes the environment, and causes the nuisance. In order to solve the hard bottleneck problem in the use of phosphogypsum, the development and application of phosphogypsum are imminent, but more difficult [1,2]. Currently the mature phosphogypsum application process technology in the implementation process will consume a certain amount of energy in China, for example calcining of the raw material in the production process and autoclave curing of phosphogypsum products will consume a lot of fuel coal and hydropower resources, which is contrary direction of the world's low-carbon economy and low-carbon building materials [3,4].

In this paper, non-calcined gypsum is used as the main raw material, followed by the modified impurity, aging, balling, cement coating process, the vibration compression molding, the nature conservancy and other process steps are used, and a high water resistance phosphogypsum blocks are produced. Their various performance indicators have reached the MU7.5 grade requirements of normal concrete small hollow block on the GB 8239-1997. And because its production process does not need the calcined gypsum and autoclave curing of phosphogypsum blocks, compared with the traditional method to produce gypsum products [3,4], the small hollow block production process is more energy efficient, consistent with the direction of Chinese current the development of low-carbon, friendly environment, energy-saving building materials, and also provides a new way to solve the problem of comprehensive utilization of phosphogypsum.

1 Experiment

1.1 Raw materials

(1) Phosphogypsum is purchased from the discharged phosphogypsum yard of a phosphoric acid production enterprise in Zhanjiang City, Guangdong Province, China, and its composition is shown in Table 1.

Table 1 Chemical composition of phosphogypsum

SO_3	Al_2O_3	CaO	MgO	SiO_2	Fe_2O_3	P_2O_5	F^-	ignition loss	crystal water	PH
38.28	0.82	29.42	0.53	10.36	1.49	1.95	0.25	17.62	16.90	4.8

(2) Quicklime is purchased form a quicklime factory in Pingnan City, Guangxi Province, China. Quicklime is grounded to 200 mesh with sieve residue less than 15%, the effective CaO content is greater than 80%, digestion time is 3~4 min, digestion temperature is 90 ℃, and quicklime is rapidly digested lime.

(3) Cementitious materials are P.O 42.5R Conch, China.

(4) Gravel is from sand and stone market in Zhanjiang City, Guangdong Province, China.

1.2 Experimental method

(1) modifying of phosphogypsum: a certain amount of gypsum and quicklime are dryly mixed, kept stirring, sprayed with water mist, aged 1 days to make the quicklime fully digest and react sufficiently with harmful impurities of phosphogypsum, and the modified phosphogypsum powder is prepared.

(2) Preparation of phosphogypsum ball: the modified phosphogypsum powder balls via a ball machine, and phosphogypsum ball is obtained; and on this basis of its parcel handling of cement, cement coated phosphogypsum ball is obtained.

(3) Sample preparation and performance test: The above modified phosphogypsum powder, phosphogypsum ball, cement coated phosphogypsum ball, cement and gravel are mixed with a certain amount of water, added into block machine, made small hollow block size of 390mm × 190mm ×190mm, aged for conservation under natural conditions, and tested the performances. All performance tests are in accordance with the test methods for normal concrete small hollow block on the GB 4111-2013[5,6].

2 Results and analysis

2.1 Effect of quicklime addition on the modification of phosphogypsum and performance of small hollow block

From the phosphogypsum component analysis, as shown in Table 1, phosphogypsum contains a certain amount of soluble phosphorus (as P_2O_5) and soluble fluorine (in F^- meter), if the impurity processing of these soluble impurities are not carried out, it will adversely affect the performance of phosphogypsum small hollow blocks, especially the compressive strength and softening coefficient [7,8]. Quicklime was added to impurity and fully mixed with phosphogypsum by adding an appropriate amount of water, the soluble impurities were transformed into insoluble or poorly soluble substances by chemical reaction, which eliminates the effect of the soluble impurities on performance of phosphogypsum blocks, the involved chemical reactions are:

$$CaO + H_2O = Ca(OH)_2$$

$$3Ca(OH)_2 + P_2O_5 = Ca_3(PO_4)_2 \downarrow + 3H_2O$$

$$2F^- + Ca^{2+} \rightarrow CaF_2 \downarrow$$

Calculated from the above reaction formula, in order to enable soluble phosphorus and fluorine of phosphogypsum completely convert to insoluble or poorly soluble material, the additive amount of quicklime was about 3%.

Meanwhile, in order to investigate the quicklime addition on properties of phosphogypsum small hollow blocks, 1%, 2%, 3%, 4%, 5%, 6% quicklime (relative phosphogypsum mass) was modified, aged for 1 days, phosphogypsum small hollow block samples were obtained by using vibration compression molding with the ratio of the modified phosphogypsum powder, cement and gravel of 5:1:4, 10% water, the pressure of 15MPa, and natural curing after ejection for 28 days, the compressive strength and softening coefficient are measured, the test results are shown in Fig.1 and Fig.2.

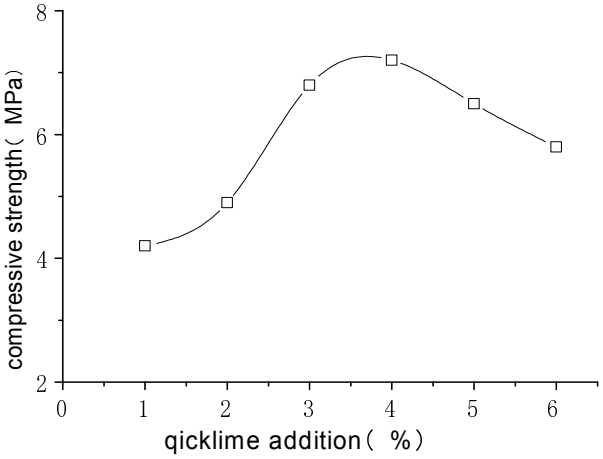

Fig.1. Effect of quicklime addition on the compressive strength of block

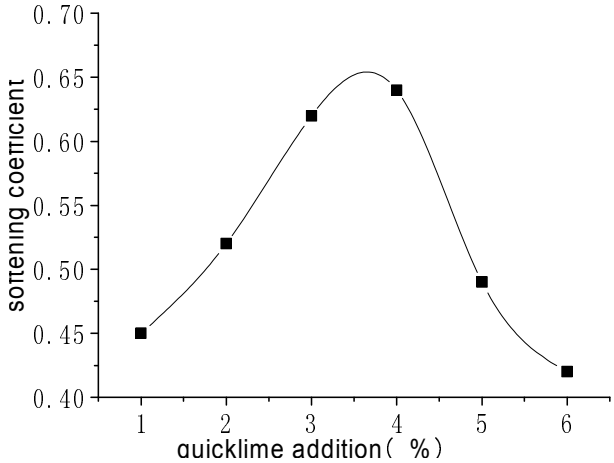

Fig.2. Effect of quicklime addition on the softening coefficient of block

Fig.1 and Fig.2 show that the compressive strength and softening coefficient of phosphogypsum small hollow blocks increased first and then decreased with the increasing of the amount of quicklime. When quicklime was less than 3%, the compressive strength and softening increased significantly, when it is 4%, two performance index reached maximum, then decreased with the increasing of the amount of quicklime. And it can be seen from Fig.2 that when the amount of quicklime was over 4%, the softening coefficient of phosphogypsum small hollow blocks significantly decreased. The reason may be that when the amount of quicklime is less than 3%, the soluble phosphorus and fluorine impurities of phosphogypsum could not completely be converted to insoluble or poorly soluble substances, leading to the compressive strength and softening coefficient of resulting small hollow block low; if quicklime was greater than 4%, although the soluble phosphorus and fluorine impurities of phosphogypsum have been converted to insoluble or poorly soluble substance, there is quicklime participate in the reaction (or known as f-CaO), the compressive strength of prepared phosphogypsum small hollow blocks decreased due to residues of these quicklime, and the block body will swell after soaking in water, resulting in softening coefficient blocks significantly lower. So the ideal dosage of quicklime was 4%, slightly larger than the previous calculation results, which can be considered that part of the acid-base neutralization reaction was involved, and the compressive strength and softening coefficient of phosphogypsum small hollow blocks were 7.2 MPa and 0.62, respectively.

2.2 Effect of phosphogypsum treatment on the properties and morphology of phosphogypsum small hollow blocks

As is known from the previous experiment, when the amount of quicklime was 4% of phosphogypsum, the compressive strength and softening coefficient of phosphogypsum small hollow blocks were 7.2 MPa and 0.62, respectively if the materials were mixed in powder, the compressive strength had reached standard requirements of normal concrete small hollow block on the GB 8239-1997, but their softening coefficient was still low. In order to improve the softening

coefficient of phosphogypsum small hollow blocks, the modified phosphogypsum was balled into phosphogypsum powder, coated with cement, and the prepared phosphogypsum balls and cement coated phosphogypsum balls are shown in Fig.3 and Fig.4, respectively. And referring to the molding process and formula described in 2.1, phosphogypsum small hollow blocks were prepared, maintained to the age, the softening coefficient and compressive strength were tested. The compressive strength and softening coefficient of phosphogypsum small hollow blocks obtained with different treatment process are shown in Fig.5 and Fig.6.

Fig.3. Phosphogypsum balls

Fig.4. Cement coatedphosphogypsum balls

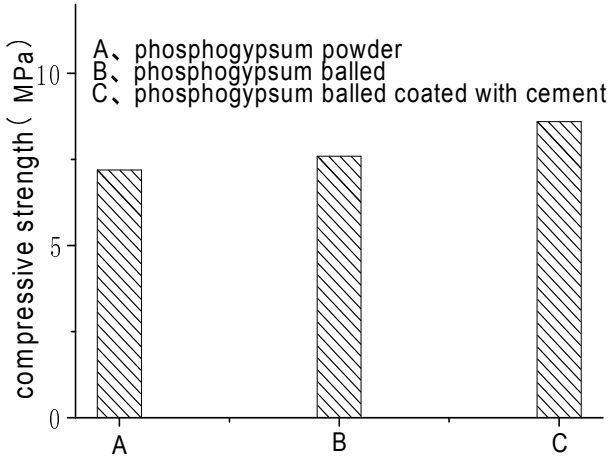

Fig.5. Effect of treatment process on the

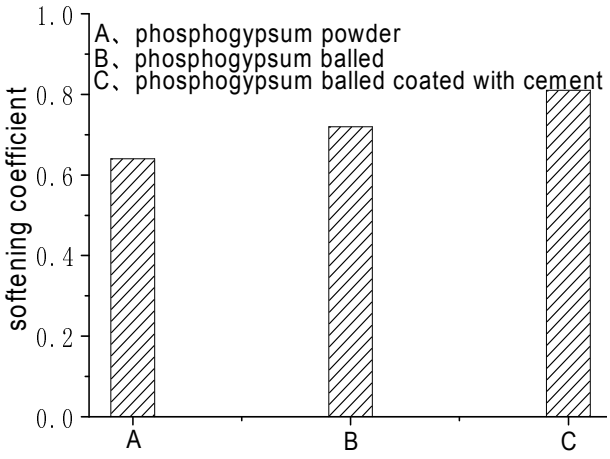

Fig.6. Effect of treatment process on the softening coefficient

Fig.5 and Fig.6 show that the compressive strength and softening coefficient of the obtained modified phosphogypsum small hollow block powder after balled and cement coated were improved, and its compressive strength and softening coefficient were 7.2 MPa and 0.66, respectively, compared with 7.6 MPa and 0.74 before balling; based on balling, the compressive strength and softening coefficient of the obtained phosphogypsum small hollow blocks after coated with cement dramatically increased to8.6 MPa and 0.82, respectively, compared with 7.2 MPa and 0.64 before balling, which has basically met the requirements of normal concrete small hollow block on the GB 8239-1997 standard MU7.5 grade index, indicating the compressive strength and softening coefficient of phosphogypsum small hollow blocks after modified, balled and coated with cement could be significantly improved. The main reason is that the surface of phosphogypsum just treated by balling is very rough (Fig.3), and there is a gap between the crystal for the phosphogypsum small hollow blocks through hydration reaction (Fig.7), the moisture easily penetrated the inside of ball, and the gypsum dissolved, resulting in a softening coefficient and strength decreased low; the surface of the phosphogypsum ball coated with cement became

relatively smooth (Fig.4), the surface of the phosphogypsum ball coated with cement after hydration reaction had no voids (Fig.8), effectively blocking the invasion of moisture, thereby improving the compressive strength and softening coefficient of phosphogypsum small hollow blocks.

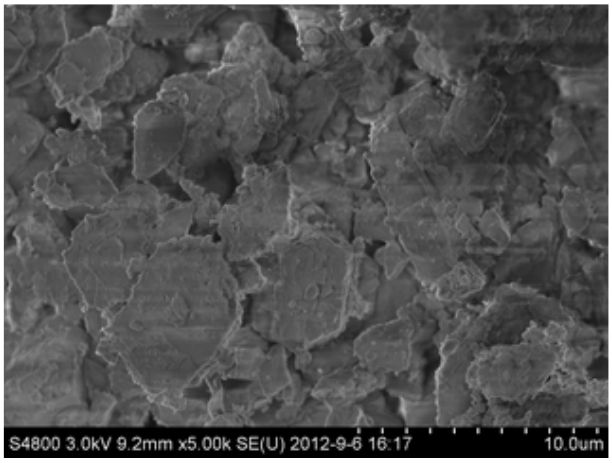

Fig.7. SEM images of the surface of phosphogypsum blocks

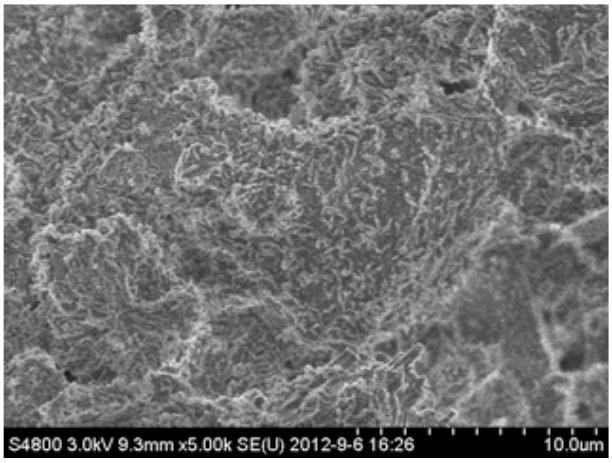

Fig.8. SEM images of the surface of phosphogypsum blocks coated with cement

2.3 Analysis of water-resistant and high-strength phosphogypsum small hollow blocks

With the above modification process and the molding process, the obtained phosphogypsum small hollow blocks tested with the Chinese statutory construction material product quality inspection institutions, their performance indicators are shown in Table 2.

Table 2 Test results of phosphogypsum blocks

Test items		Unit	Test results	Judgement
Compressive strength		MPa	8.60	According to the requirements of the standard GB 3289-1997
Core ratio		%	42	
Frost resistance	Mass loss	%	1.5	
	Strength loss	%	22.8	
Comparatively percentage of moisture		%	38.0	
Radionuclide Specific activity	^{226}Ra	Bq/kg	50.72	According to the requirements of the standard GB 6566-2010
	^{232}Th	Bq/kg	32.60	
	^{40}K	Bq/kg	753.58	
Building material standard request	I_{Ra}	---	0.25	
	I_r	---	0.44	
Softening coefficient		--	0.82	According to the requirements of the general concrete products

As can be seen from Table 2, the performance such as compressive strength drying shrinkage, and softening coefficient of the prepared phosphogypsum small hollow blocks with the above ratio met the MU7.5 grade requirements of normal concrete small hollow block on the GB 3289-1997; as can be seen from Table 2, development and production of radioactive phosphogypsum bricks met the main building material requirements of limited building radionuclide on the GB 6566-2010. Comprehensive analysis of the performance indicators of phosphogypsum small hollow block shows that the water was not only high-strength phosphogypsum small hollow blocks could be widely used in interior and exterior walls of buildings, but also could replace the ordinary the

general concrete products used in cable trenches, guide ditches and other municipal projects, thus expanding their application scope, which will provide a new way to solve the comprehensive problem of phosphogypsum for the further utilization .

3 Conclusion

(1) Phosphogypsum was modified by the use of quicklime, followed into a ball, coated with cement, aged, which not only effectively removed soluble phosphorus, fluorine and other impurities on the adverse effects of phosphogypsum small hollow blocks, but also significantly improved the compressive strength and softening coefficient and other properties of phosphogypsum small hollow blocks.

(2) The mixed raw material ratio of modified, balled, cement coated phosphogypsum: gravel: cement of 50:40:1, 10% water, pressure of 15 MPa, and vibration compression molding was used, the nature conservancy maintained to 28 days after stripping, the performance targets of prepared phosphogypsum bricks had met or exceeded the standard MU7.5 grade index requirements of normal concrete small hollow block GB 8239-1997.

(3) The prepared phosphogypsum small hollow blocks belonging to the new building materials, had high strength and water resistance, which provided a new way to solve the comprehensive problem of phosphogypsum for the further utilization.

Keywords: Nanometer copper film; Laser micro shock processing; electrical resistivity

Abstract: The aim of this research is to improve the electrical performance of the nanometer copper film by laser micro shock processing. The nanometer copper film was prepared by the magnetron sputtering. The mechanism of laser micro shock processing effect on electrical resistivity, hardness and elastic modulus was investigated. The results show that the electrical resistivity of copper film after laser micro shock reduced by 22.5 % on average. And, the hardness and the elastic modulus increased by 38.5 % and 45.2 % on average, respectively. According to our research, we conclude that, the existence of a large number of twin, twin boundary, fault and the grow up grain are the main factor of the improvement of the electrical performance; and the existence of twin, stress concentration holes and fault are the key to improve its mechanical properties.

Introduction

Laser shock processing (LSP) is one of the most important surface modification technologies. It has been widely used in surface improvement of metal materials [1]. At present, with the rapid development of Micro/nano device, mechanical strength of the device materials and integrated electronic attachment material has become a research focus at home and abroad [2]. In this paper, the nanometer copper film prepared with on the magnetron sputtering was treated by laser micro shock processing, aiming to explore the application prospect of laser shock processing technology in nanometer thin film materials. In previous studies [3] we have shown that a large number of abundant twin, fault, space and a small amount of dislocation can be produced by laser micro shock processing. Also, we observed the grain growth phenomenon. The key point of this article is to expound the mechanism of laser micro shock processing impact on the thin film's electrical and mechanical performance.

Experiment

The copper thin film materials preparation has been detailed in our previous article. [4]. The film was prepared on JGP560CVI ultra high vacuum multifunctional magnetron sputtering equipment. The experiment was conducted on neodymium glass high power laser.

Nanoindentor produced by Hysitron company was used in this experiment. The hardness and elastic modulus of the nanometer copper film were tested by the method of nanoindentation. The device can record the load-displacement curve. Actually, the curve contains the deformation information in different depth in the indention process. So the hardness and elastic modulus in different depth can be calculated according to the curve. Computation formula of the elastic modulus is as follows [5]:

$$E_r = \frac{\sqrt{\pi}}{2}\frac{S}{\sqrt{A}} \tag{1}$$

where A is the elastic contact area, S is the initial unloading stiffness. In addition, equation (2) can be obtained by definitions of hardness of materials:

$$H = \frac{P_{\max}}{A} \qquad (2)$$

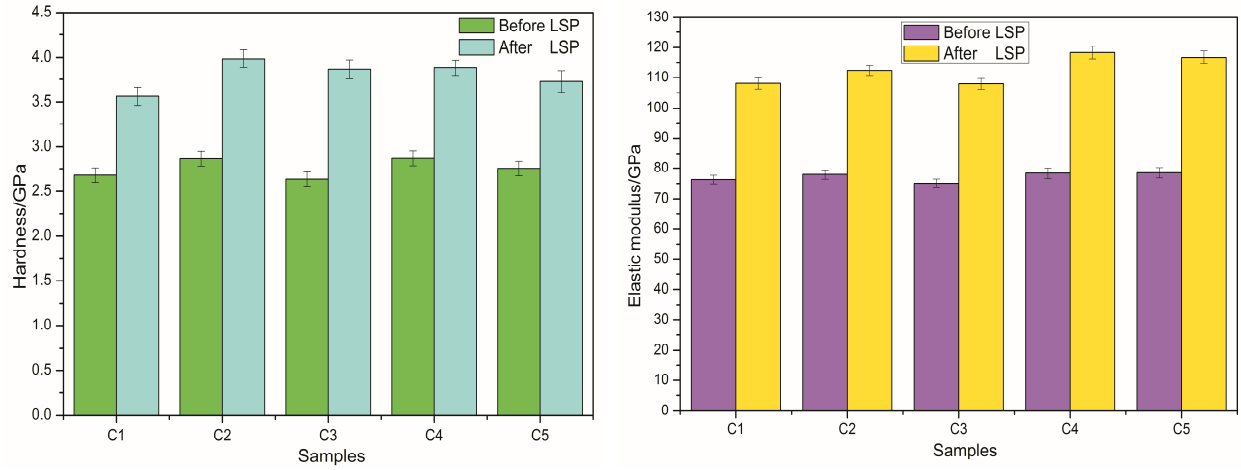
where P_{max} is the load, H is the hardness of the measured material.

According to elastic modulus E_r and hardness H in equation (1) and (2), we calculate the hardness and elastic modulus of the sample under various states of each test point, and then averaged.

Nanoindentation test were carry out in both the LSP impact area and none LSP impact area of sample C1, C2, C3, C4 and C5. The load - displacement curves for samples were obtained. The electrical resistivity test were carried out by a SZ - 82 digital four point probe tester at room temperature (293 K) at 5 points on each sample, of which take the average result was taken to be the object value.

Results

According to the data tested in the load - displacement curve and the calculated equation (1), (2), the hardness and elastic modulus in LSP impact areas and none LSP impact areas were shown in Fig. 1. As is shown in Fig. 1(a), hardness of nanometer copper films after LSP have been increased by 38.5 % on average. As is shown in Fig. 1(b), elastic modulus of samples after LSP have been increased by 45.2 % on average. The results show that the LSP improved the mechanical properties of nanometer copper films effectively.



(a) (b)

Fig. 1 Hardness (a) and elastic modulus (b) of nanometer copper films before and after LSP

Electrical resistivity of nanometer copper film is 1.112×10^{-8} Ω·m on average and coarse grained copper is $(1.691\pm0.020)\times10^{-8}$ Ω·m [oxygen free high conductivity copper (OFHC) is $(1.672\pm0.020)\times10^{-8}$ Ω·m]. This suggests that the electrical resistivity of nanometer copper film produced by the magnetron sputtering in the optimized parameters can be lower than that of OFHC.

After LSP, the electrical resistivity of the five samples above was tested according to the above method. The results are shown in Fig. 2. The experimental results show that the electrical resistivity of nanometer copper film after LSP is 0.8576×10^{-8} Ω·m on average. The electrical resistivity declines in different degrees rather than rises, with the electrical resistivity decreasing by 22.5 % on average, falling by 25.6 % to the utmost.

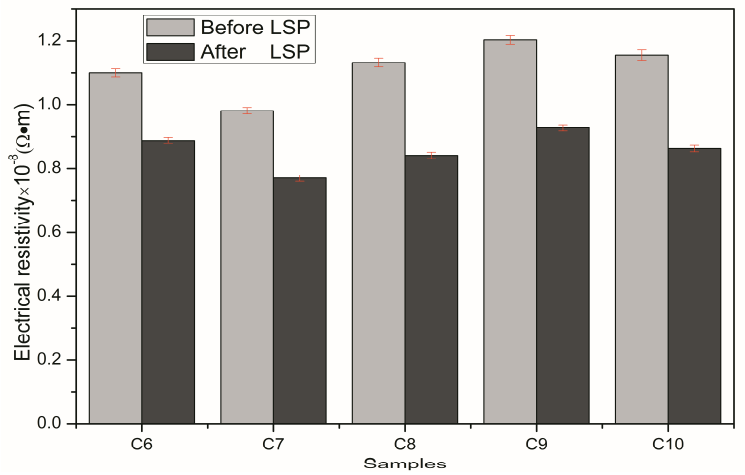


Fig. 2 Electrical resistivity of nanometer copper films before and after LSP

Discussion

Fig. 3 shows the TEM image of copper thin film without LSP. As we can see from Fig. 3 (a), the grains of copper thin film are in a quasi-static and the primary twins were overlapped with another grain (region A). Fig. 3 (b) is the detail view of B region in Fig. 3 (a). It clearly shows the quasi-static grain. A high level stress induced by LSP will make it continue grow up [5].

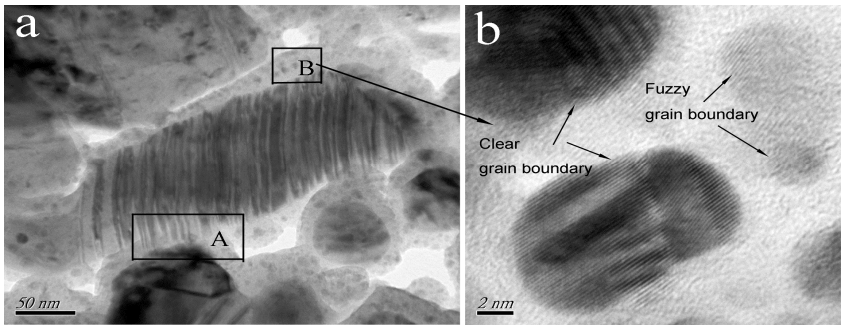

Fig. 3 TEM image of copper thin film without LSP

(a) quasi-static grain and the primary twin (b) detail view of B region in Fig. 3 (a)

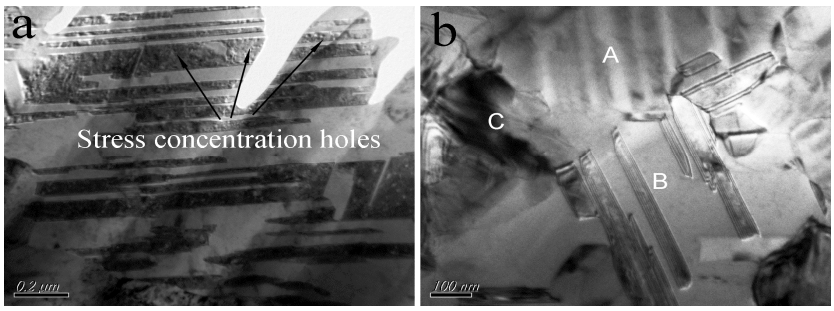

Fig. 4 TEM image of copper thin film after LSP. (a) The transgranular growth twin and the stress concentration holes (b) twin and dislocation

The TEM image of copper thin film after LSP has been shown in Fig. 4. Fig. 4 (a) is the transgranular growth twin and the stress concentration holes. From Fig. 4 (b), we can observe primary twin organization with fuzzy grain boundary in A region. There are complete twin organizations in B region, with very instinct grain boundary. A large amount of dislocation can be found in C region. We found that dislocation can rarely be found in the organization after LSP. Where there is an obvious twin produced, there is no dislocation, and where there is no twin produced, there is a little amount of dislocation. It means that the consistency of the lattice structure is not easy to produce dislocation defect within a single element metal film.

After LSP, the biggest characteristic of the copper thin film organization change is the slip deformation. As we all know, the dislocation slip is one of the line slip deformation, which needs very small energy compared with the surface sliping deformation. Although we found the grains have a grow up phenomenon, the substructure in the twin are very small and the width of the twin is only a few nanometers to tens of nanometers. Coherency distortion of the twin enhances the material's ability to resist deformation, the hardness and elastic modulus. The existence of the stacking fault also improves the material's mechanical properties. A large number of vacancy defects form in the process of atomic plane slip. These vacancy defects are equivalent to the dislocation tangles and played an important role of "pinning" in the deformation process. Their existence will improve the nanometer copper thin film's mechanical properties, too.

Data show that the room temperature resistivity of copper in the grain boundary and in the stacking fault is 3.6×10^{-16} Ω·m and 3.4×10^{-17} Ω·m [6]. Resistivity of coherent twin boundary is about half of that of stacking fault, i.e. 1.7×10^{-17} Ω·m for the copper [7]. Resistivity introduced by twin boundary is far less than that introduced by grain boundary, so we can think that the increase in the total resistivity comes mainly from the grain boundary and the high density of twin boundary.

5. Conclusions

Through the experimental study and theoretical analysis, the following conclusions can be drawn:

1) The electrical resistivity of nanometer copper film after LSP, instead of increase, is reduced by an average of 22.5 %. After LSP, the hardness and elastic modulus of the nanometer copper film increase by 38.5 %, 45.2 %, respectively;

2) The existence of a large number of twin, twin boundary, fault and the grain growing up are the main factor of the improvement of the electrical performance. The existence of twin, vacancies and fault are the key to improve the mechanical properties.

Keywords: Laser metal deposition shaping; Numerical simulation; Process parameters; Residual stress

Abstract. In order to improve the quality of sample and decrease the stress during process, it is important to study the residual stress distribution during direct laser metal deposition (LMDS) process. In this paper, according to the "element life and death" technique of finite element method ,with APDL, we simulated the effects of Laser power, scanning velocity, substrate preheat temperature and powder addition speed in top layer of samples residual stress distribution during whole LMDS process are studied. The residual stress distribution under different process parameters is researched in detail. Using the same process parameters, the simulation results show good agreement with the features of sample which fabricated by LMDS.

Introduction

Laser metal deposition shaping (LMDS) technique has been widely used in many industrial applications such as aerospace，automobile，weapons and so on [1][2]. LMDS accumulates metal powder materials according to two-dimensional profile information one layer off another, and finally the three-dimensional solid parts are formed in substrate, with the laser cladding method. And it's a fusion and solidification process essentially, which involves complicated interactions between the laser beam, metal powders, the base material (substrate), and processing gases. Typical physical phenomena in laser cladding include laser-powder interactions, heat transfer, fusion, and solidification. There are approximately variables which strongly influence the characteristics of the clad part. These variables include actual laser power, spatial distribution (model) of the laser beam, powder delivery gas flow, powder feed rate, material parameters, powder parameters, powder carry method, height increment per layer, percentage overlap between tracks, and tool-path patterns. Some of these processing parameters are strongly coupled with each other. These processing parameters are necessary to obtain the desired dimensional accuracy and material integrity of laser clad parts. Process optimization requires both theoretical and experimental understanding of the associated physical phenomena.

In the past decades, many analytical and numerical LMDS models have been developed by researchers, revealing the temperature gradient [3]-[10], as human people difficult to measure many of the physical phenomena, directly. Recently, three-dimensional laser forming simulations have been conducted using commercial FEA software or manual programming. Long et al [7][10] developed a three-dimensional dynamics stress field under different scanning method and substrate preheat temperature during multi-track & multi-layer laser metal deposition shaping(LMDS) process with ANSYS parametric design language (APDL).In their work, a multi-track & multi-layer part was deposited on a substrate，and the temperatures of those nodes in molten pool were set as the melting point at each incremental step.

In this paper, according to the "element life and death" technique of finite element method, with APDL, we simulated the effects of Laser power, scanning velocity, substrate preheat temperature and powder addition speed in different top layer of samples reciprocating scanning method to residual stress distribution during whole LMDS process. The residual stress distribution under different process parameters are studied in detail. With the same process parameters, the samples fabricated by LMDS show good agreement with the simulation results.

Model of finite element method

As shown in Fig.1 based on “birth and dead element” technique ,we built the model of finite element method of LMDS with APDL(ANSYS Parametric Design Language).

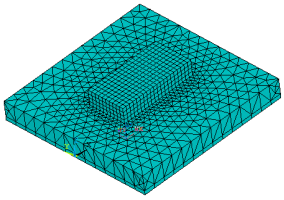

Fig.1. The FEM model

The overall computational domain size is 20mm*10mm*4mm in X, Y and Z. The size of grid is 1mm*1mm*1mm, and the element is SOLID5. The metal material of both the clad and substrate are TC4 (Ti-6Al-4V). The chemical compositions are listed in Table 1, and its partial thermo-physical parameters are listed in Table 2.

Simulation results and analysis of the Residual stress distribution

In this model, we set the processing parameters as follows: the laser power is 2000W, the radius of the beam is 1mm, the scanning velocity is 5mm/s, the scan pitch is 1mm, the environmental and substrate preheating temperature both are 20°C. The whole process lasts for 360 seconds. (Processing time 160s + cooling time 200s). The process parameters are listed in Table 3.

Fig.5. The residual stress distribution on different directions of top layer under different powder speed rate

It is shown that the X-ray and Y-ray residual stress distribution on each top layers under different process parameters in Fig.2. We can see the X-ray and Y-ray residual stress were strong in ends of the sample. Because of The laser scanning from left side of top layer to start, as the scan in the right side of third layer had just finished, the temperature gradient changed gently. Distribution of residual stress under different process parameters in middle of each layers of piece is small. Because the temperature gradient changes greatly at starting point of top layer, the residual stress is centralized. The residual stress on the top layer rises with ascending of laser power.Similarly，in Fig3-5, we can discover that the residual stress on the top layer reduces with ascending of scanning velocity; The residual stress on the top layer reduces with ascending of substrate preheating temperature; The residual stress on the top layer reduces with ascending of powder speed rate.

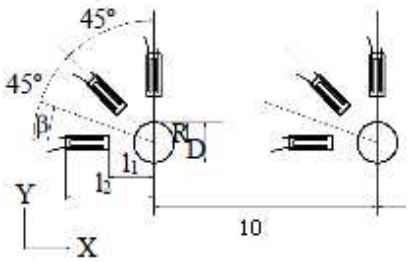

Fig.6. The schematic of residual stress testing

Comparisons to experimental results

For detected the residual stress distribution in the sample, for compare with the numerical results, we used the same processing parameters. We measure the residual stress with blind-hole method[11]. The experimental procedure is that:

For the strain slice connected tightly with sample, we should be pre-processing the sample before pasting strain slice on the sample.

The strain slice pasting as in Fig.6 shown.

To avoid the effects of drilling thermal, we measured the strain with average method. We should that read the strain values and average them every 5 minutes, after drilled at least 40 minutes.

We obtained the fixed-point measuring result of residual stress variations at the ends and middle points on the top of the sample as in Fig.7-14 shown.

Fig.8. The residual stress distribution under different Laser power on Y-ray of surface of samples

In Fig.7 shown that The residual stress distribution under different Laser Powers on X-ray of surface of samples. we can see under Laser Power 2000W and Laser Power 2200W (In Fig 7(b)and (c)), Both of the residual stress distribution in the top of sample are similar. The σ_y change amplitude is small, both are tensile stress and change from 0 to max at the middle point, and getting smaller to 0, then getting to shrinkage stress and the value of the stress getting larger. We can explain about σ_x in this way, but x- change amplitude just than more σ_y larger. In Fig.8(a) shown, x is mainly shrinkage stress. At the middle point, it is minimum value, then it getting larger. but σ_y was just contrary to σ_x, mainly tensile stress, at the middle point ,it is minimum value. it is similar to the Fig.2(a).We able to explain about Fig.8， It similar to the Fig.2(b).

In the same way we can explain about Fig 9-14.

Conclusions

According to the “element life and death” technique of finite element method ,with APDL, we simulated the effects of different process parameters to residual stress distribution during whole LMDS process are studied. The residual stress distribution under different scanning methods is researched in detail.

The residual stress on the top layer reduces with ascending of scanning velocity; The residual stress on the top layer rises with ascending of laser power; The residual stress on the top layer reduces with ascending of substrate preheating temperature; The residual stress on the top layer reduces with ascending of powder speed rate.

Using the same process parameters, the simulation result show good agreement with the features of sample which fabricated by LMDS.

Keywords: Benzene; Plasma; Glow Discharge Electrolysis; Hydroxyl Radicals

Abstract. Removal of benzene and effects of various parameters on the removal efficiency in the aqueous solution with plasma are studied. Results indicated that the degradation rate can be considerably raised by prolonging the discharge time, removal proceeded faster when the treatment was conducted in alkaline or acidic than in neutral media. Fe^{2+} shows an evident accelerated effect on the benzene elimination, and the presence of H_2O_2 benefited the degradation. It is demonstrated that the hydroxyl radicals were the most responsible oxidants in the benzene degradation. The major intermediate products resulted from the degradation were identified by an HPLC analysis and a degradation path way was proposed.

Introduction

Volatile organic compounds (VOCs), emitted from chemical, petrochemical, and related industries, have received increased attention in recent years. Benzene, one of the most prevalent VOCs, is a naturally occurring aromatic compound present in petroleum fuels and is a frequent contaminant in both surface and subsurface environments. When benzene diffuses into the environment, it poses great threats to human health, such as drowsiness, dizziness, unconsciousness, and an increased risk of cancer [1]. Because of its high toxicity, confirmed carcinogenicity, and environmental persistence, it is regarded as the priority hazardous substance [2]. The development of an efficient, mild and cost-effective technology for benzene degradation in the ambient environment is absolutely necessarily.

Several advanced oxidation process, such as ultraviolet photolysis, TiO_2-based photocatalytic oxidation, direct ozonation, electron beam and various combinations of radiation are currently under development [3,4]. In this process, the attention has been focused on hydroxyl radical, since the most powerful oxidizing species are in fact the hydroxyl radical. The hydroxyl radical reacts strongly with all organic substances usually by hydrogen abstraction.

Contact glow discharge electrolysis (CGDE) is a novel type of electrochemical process in which plasma was directly produced by the electrical discharge against water. Because of its high efficiency, high amenability to automation and environmental compatibility in which high energy of plasmas, CGDE were directly produced by the water discharge were mostly utilized for the destruction of hazardous organics in the aqueous solution. In this process, $HO\cdot$ radical are produced electrochemically in an anodic reaction directly from water. By using the electrochemical production of hydroxyl radicals, no addition of chemical substances is necessary and the process can be performed at affordable costs, determined mainly by the power required for driving the electrochemical process and without the common AOP drawbacks. The mechanism of producing plasmas in this process has been studied by M. A. Malik and so on [5-7]. Recently, there were several reports [8-10] on the degradation of certain organic target compounds dissolved in water by use of contact glow discharge. All these investigations confirm that contact glow discharge plasma was a prospective process for the degradation of toxic substances.

In the present paper, benzene was chosen as a model pollutant dissolved in potassium sulfate by means of glow discharge electrolysis under water in order to further study the degradation behavior of benzene, focusing on the reaction kinetics and the mechanism aspects.

1. Experimental

The experimental apparatus consists of a reaction cell and a high voltage power supply as showed in Figure1. The experimental apparatus is schematically identical to that mentioned in the literature [10]. It consists of a reaction reactor and a high voltage power. The electrode system consisted of a platinum wire anode (I.D. 0.5 mm) and a stainless steel rod (I.D. 0.5 cm) cathode with an electrode distance of 3 cm. The anode was encased in a glass tube located in the bottom center of a glass cylinder reactor (inner diameter=6.5 cm, length=20 cm), with the needle tip protruding 1 mm from the glass tube. The cathode was inserted through the top of the reactor. In addition, the reaction cell was coated by a water jacket, in which the temperature was controlled at room temperature. A positive high voltage was applied to the needle anode by a WYJ-1000V2A dc power unit produced by Shanghai Changjiang Electron Instrument Company providing voltage of 0-1000 V and current output of 0-2 A.

The benzene solution was prepared by dissolving analytical grade benzene in a potassium sulfate solution ($1g \cdot L^{-1}$). The pH of the aqueous solution and electric conductivity were adjusted with dilute sodium hydroxide, dilute sulfuric acid and potassium sulfate to the expected value. During the reaction, a small portion of the solution (0.025 ml) was periodically sampled out from the sampling port with a finnpipette made by Thermo Electron Corporation to measure the reduction of benzene immediately by a UV-V spectrophotometer (SPECORD50, Analytic Jena) and HPLC (LC-10AT vp, Shimadzu Company) respectively.

The experiments were performed under the conditions as follows: volume of electrolyte, 200 ml; initial concentration of benzene, 100 $mg \cdot L^{-1}$; voltage, 700 V; initial pH, 6.89; temperature, 298K. The maximum absorption wavelength is 194 nm. These are referred as the “standard conditions” or otherwise specified.

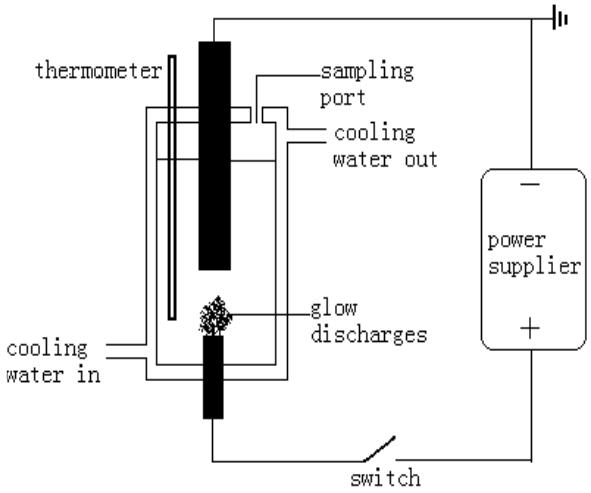

Fig.1. Scheme of the experimental apparatus

2. Results and discussion

2.1 Removal of the benzene

The oxidative degradation of benzene proceeded abruptly when glow discharge electrolysis was carried out on the solution containing it. Figure 2 exhibits the time profile of benzene removal under 700V. The initial concentration(c_0) of benzene was 100 $mg \cdot L^{-1}$. It can be seen that the benzene removal increases with the discharge time. This indicates that glow discharge electrolysis is a very efficient tool for benzene degradation because generally the pollutant cannot be completely removed in other processes.

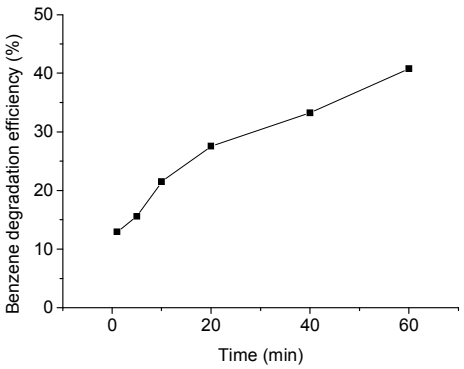

Fig. 2. Time profile of benzene degradation

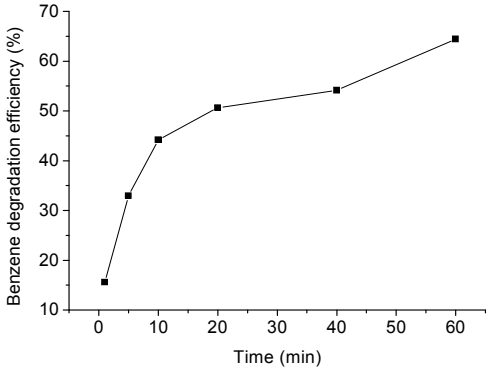

Fig. 3. Accelerating effect of H_2O_2 on benzene degradation

2.2 Effects of and hydrogen peroxide

In order to investigate the role of H_2O_2 in removing benzene from the aqueous solution, H_2O_2 (100 mg·L^{-1}) was added into the benzene solution respectively. Figure 3 shows the concentration of the benzene at reaction time from 1 to 60 minutes. Obviously, the removal efficiency of 100 mg·L^{-1} with H_2O_2 is higher than without H_2O_2. It is also observed that the higher H_2O_2 concentration is beneficial to removel of organic compounds. It may be explained that the concentration of HO· is increased when H_2O_2 was added into the benzene solution.

2.3 Accelerated effect of ferrous ions

It is well known that the ferrous ion could react with hydrogen peroxide and produce hydroxyl radicals with powerful oxidizing abilities to degrade organic pollutants. Hickling et al found that the primary yield of oxidizing species was about four times larger than the case without ferrous ion in the solutions [11]. This can be achieved by Fenton's reaction, therefore, some ferrous sulfate was added into the solution and results were shown in figure 4. The initial concentration of benzene was 100 mg·L^{-1}, pH value was 6.89 and applied voltage was 700V. It can be seen that Fe^{2+} has an evident catalytic effect when its concentration is more than 2×10^{-3} mol·L^{-1}. Therefore, 2×10^{-3} mol·L^{-1} is the optimum concentration of the catalyst under experimental conditions.

The reason is as follows:

$$H_2O_{gas} - e \rightarrow H_2O^+_{gas}$$

$$H_2O^+_{gas} + (n+1)\,H_2O \rightarrow H_3O^+ + (n+1)\,HO\cdot + n\,H\cdot$$

$$HO\cdot + H\cdot \rightarrow H_2O$$

$$2HO\cdot \rightarrow H_2O_2$$

$$Fe^{2+} + H_2O_2 \rightarrow Fe^{3+} + HO\cdot + OH^-$$

$$Fe^{2+} + HO\cdot \rightarrow Fe^{3+} + OH^-$$

$$OH\cdot + H_2O_2 \rightarrow H_2O + HO_2\cdot$$

$$Fe^{3+} + H_2O_2 \rightarrow Fe^{2+} + HO_2\cdot + H^+$$

$$OH\cdot + H_2O_2 \rightarrow H_2O + HO_2\cdot$$

From the above reactions, it can be found that in the presence of Fe^{2+}, the H_2O_2 produced by the discharge was converted to HO· again, which in turn, accelerates the degradation. In addition, it was found that the most favorable pH is 5.6 in the presence of Fe^{2+}, this maybe due to the synergistic effects of the coagulation action of $Fe(OH)_3$ produced by the induced reaction.

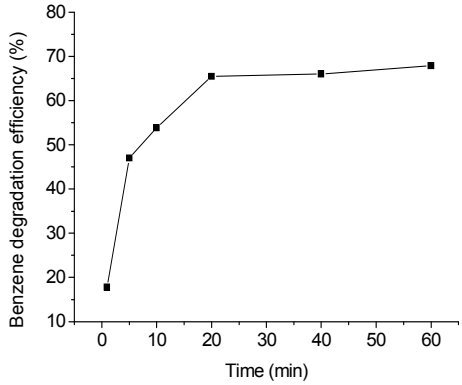

Fig. 4. Effects of ferrous sulfate（2×10^{-3} mol·l^{-1} $FeSO_4$）

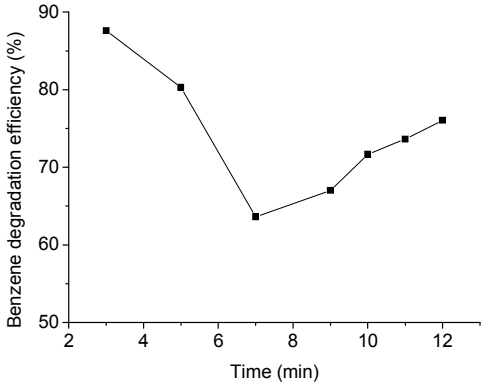

Fig. 5. Effects of pH on benzene removal

2.4 pH Effects

Since the pH often plays an important role in the wastewater treatment, we studied the effects of initial pH on the degradation of benzene. Figure 5 shows the results of a series of experiments at different pH at given reaction time 30min. The initial conditions for the model were as follows: benzene concentration (c_0) was 100 $mg \cdot L^{-1}$ and applied voltage was 700V. A faster benzene removal rate can be achieved for a relatively higher alkalinity or acidity. As we already know, the oxidative ability of plasma is stronger in acidic conditions. When the solution was basic, the amount of the plasma is increased and the charge distribution of the reactant changes, which makes it favorable to attack of the OH· free radicals. Because most of the wastewater is acidic or basic, it does not need pH adjustment.

2.5 Intermediate products and degradation mechanism

In order to obtain the reaction path, a series of experiments were carried to determine the intermediates by HPLC under normal conditions, that is, without any other substance added (Fig. 6). By the detailed analysis of the intermediate products and kinetic consideration, it was proposed that the reaction of benzene with the hydroxyl radical might lead to the formation of methanoic acid, acetic acid, oxalic acid and so on as the primary products. In the end, all of the carboxylic acids were decomposed into inorganic carbon, which might exist as bicarbonate or carbon dioxide. These results were in agreement with that of references [9,10].

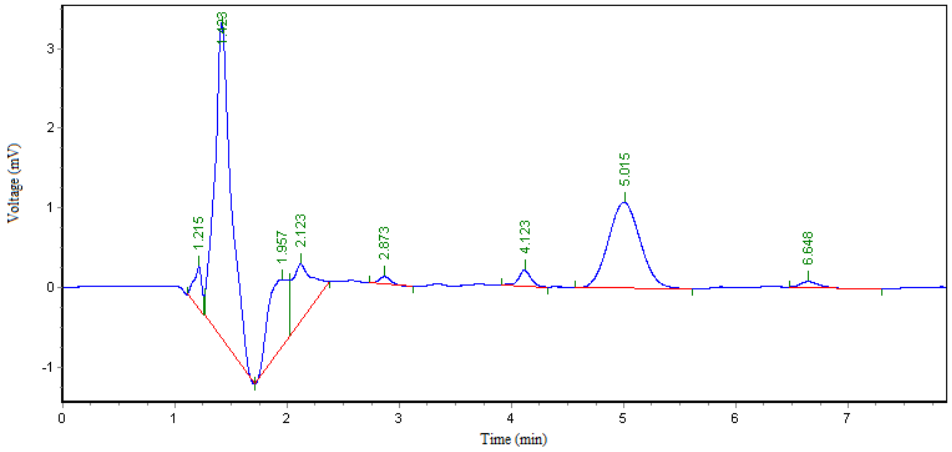

Fig. 6 HPLC chromatogram of intermediate products at 10 minutes of degradation.

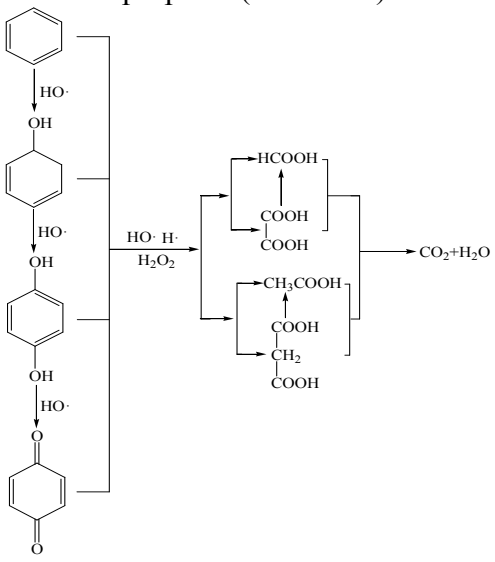
The operating conditions: Column, Luna 5u C18; Mobile phase, acetonitrile-phosphate suffer (20 %) =40:60(V/V); Pressure, 14.2 M Pa; Wavelength, 254 nm; Flow rate: 1.0 ml/min.

Based on previous studies [9,13] and the above discussion, a possible mechanism for the benzene degradation with CGDE can be proposed(Scheme 1).



Scheme 1. The mechanism for the benzene degradation with CGDE.

3. Conclusion

From the above experiments, the following conclusions can be drawn:

i) Benzene can be rapidly and exhaustively degraded by glow discharge electrolysis in water. The final product was inorganic carbon.

ii) Faster benzene removal rate can be achieved for a relatively higher alkalinity or acidity.

iii) The degradation can be greatly accelerated in the presence of Fe^{2+} and H_2O_2.

These wonderful results suggest that glow discharge electrolysis is an efficient tool for degradation of benzene, and further study is under way.

Keywords: Rhodamine B; plasma; glow discharge; degradation; hydroxyl radicals

Abstract. Exhaustive Rhodamine B oxidation by means of contact glow discharge plasma in aqueous solution has been investigated. The rate of degradation in different conditions such as pH, H_2O_2, Fe^{2+}, n-butanol, and other factors affecting was studied. The results showed that, there are faster removal rate when the solution was in a relatively higher acidity; H_2O_2 presence can improve the efficiency rate.Fe^{2+} can promote reaction. Radical scavenger, n-butanol, inhibits the Rhodamine B removal significantly. Some major intermediate products were detected by HPLC and GC-MS, respectively.

1. Introduction

Rhodamine B（RhB) is a cationic very stable dye. It has the xanthene structures and often as cationic molecular model of refractory organic pollution. Because it`s stability and the dyeing ability， RhB is widely used in industry and will cause great damage to the water environment[1-2].The treatment of wastewater containing RhB is very important. Because many anti microbial degradation of dye，the study of many physical and chemical treatment of wastewater containing such aselectrochemical oxidation, ozonation and biological treatment etc[3-5].

The most suitable alternative method is advanced oxidation processes (AOP), since the most powerful oxidizing species in this process are in fact the hydroxyl radical. The hydroxyl radical reacts strongly with organic substances. In this process, HO·radical are produced electrochemically in an anodic reaction directly from water which has to be treated [6] as follows:

$$H_2O - e \rightarrow H_2O^{+} \rightarrow HO\cdot + H^{+}$$
$$2HO\cdot \rightarrow H_2O_2$$
$$H_2O_2 \rightarrow O_2 + H_2O$$
$$O_2 + H_2O + 2e \rightarrow H_2O_2 + 2OH^{-}$$
$$OH^{\cdot} + H_2O_2 \rightarrow H_2O + HO_2^{\cdot}$$
$$H^{+} + OH^{-} \rightarrow H_2O$$

By using the electrochemical production of hydroxyl radicals, no addition of chemical substances is necessary and the process can be performed at affordable costs, determined mainly by the power required for driving the electrochemical process and without the common AOP drawbacks. Most of the researches focus on dissolved easily and low toxic substances, some of them attempted to design complex apparatus including costly diamond anodes for the COD removal from several industrial wastewaters [7-8].

Removal of RhB and effects of various parameters on the removal efficiency in the aqueous solution with plasma are studied. The anodic contact glow discharge plasma may be promising since it doesn't need any evacuating system or special power source. The mechanism of producing plasmas in this process has been studied by M. A. Malik and so on [9-11]. Recently, there were several reports on the degradation of certain organic target compounds dissolved in water by use of contact glow discharge. These reports concerned chlorophenols [12], aniline [13], phenol [14], azobenzene [15], auramine [16] and so on. All these investigations confirm that contact glow discharge plasma was a prospective process for the degradation of toxic substances. In the present paper, RhB was chosen as a model pollutant dissolved in potassium sulfate by means of glow

discharge electrolysis under water in order to further study the degradation behavior of organic compounds.

2. Experimental

The experimental apparatus was comprised of a reaction cell and a high voltage power supply as illustrated in Fig. 1. The anode from which the glow discharges emitted was a pointed platinum wire (I.D. 0.3 mm) encased in a glass tube located in the bottom center of a cylinder reactor, with the needle tip protruding 1 mm from the glass tube. The cathode was a stainless steel rod placed in the opposite position of the anode. A positive high voltage was applied to the needle anode by a WYJ-1000V2A dc power unit providing voltage of 0-1000 and current output of 0-2 A （VWYJ-1000V2A）. In addition, the reaction cell was coated by a water jacket, in which the temperature was controlled at the room temperature. When the glow discharge electrolysis began, a lot of heat was produced, which can convert the solution. Therefore, no other system was employed to stir the solution.

RhB was dissolved in an aqueous potassium sulfate solution (2g/L). The pH of the solution was adjusted with dilute sodium hydroxylate and dilute sulfuric acid to the expected value. During the reaction, a small portion of the solution (0.025ml) was periodically sampled out from the sampling port to measure the reduction of RhB immediately by UV spectrometer (SPECORD50) and high performance liquid chromatography (LC-10ATvp).

The experimental conditions usually employed were: electrolyte, 150mL; voltage, 600V; temperature, 298K. The maximum absorption wavelength is 554nm.These are refered as the “standard conditions” or otherwise specified.

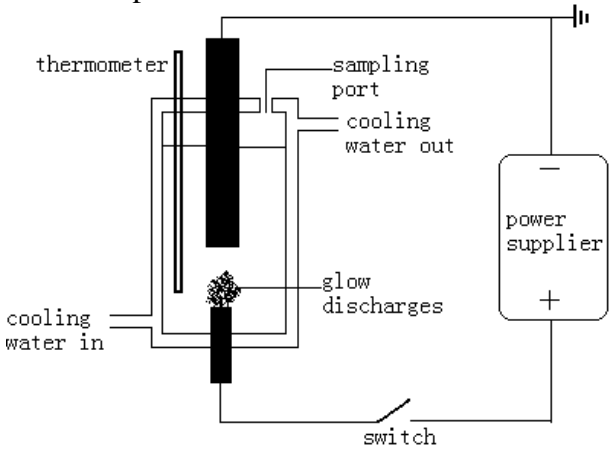

Fig. 1. Scheme of the experimental apparatus

3. Results and discussion

3.1 The characteristic curve of current vs. voltage

In order to clarify the glow discharge electrolysis underwater, a characteristic curve of current vs voltage was presented in Fig.2. A 150ml solution containing 2g/L K_2SO_4 and 100mg/L RhB was used for degeadation under defferent voltage. From the curve, it can be found that the current increased almost proportionately with the increase of the applied voltage in 0～250V, suggesting that the electrolysis observe the ohm’s law in this stage. The reaction was mainly attributed to the oxidation of water at the anode and reduction at the cathode. When the applied voltage is over 320V, the current decreased with the increasing of the voltage, this can be explained by the fact that a lot of heat was produced near the tip of the anode, making the water surrounding the anode vaporization and the current decreased because the water vaper is dielectric. From the experiment, it was found that there is almost no signs of the melting of the anode even the applied voltage increased to 700V, proving that the glow discharge electrolysis under water can widen the applied voltage range.

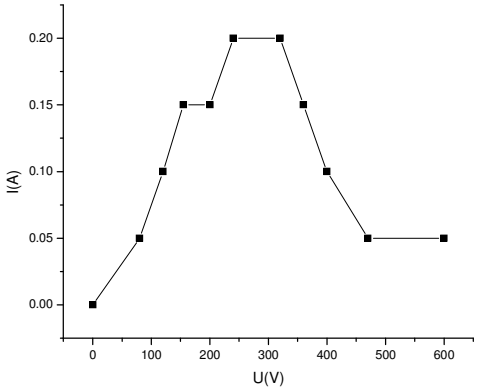

Fig. 2. The characteristic curve of current vs voltage

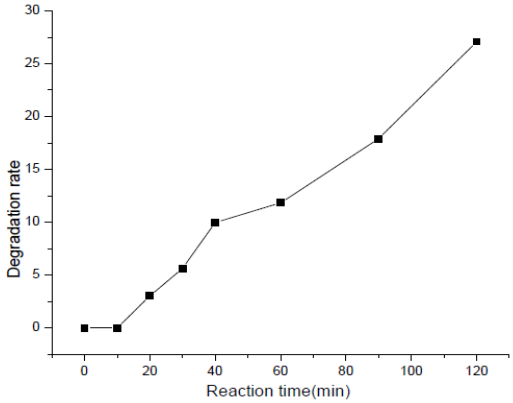

Fig. 3. Time profile of RhB degradation

3.2 RhB removal

The oxidative degradation of RhB proceeded abruptly when glow discharge electrolysis was carried out on the solution containing it. Fig. 3 exhibits the time profile of RhB removal under 600V. It can be seen that the RhB removal increases with the discharge time. This indicates that glow discharge electrolysis is a very efficient tool for RhB degradation because generally the pollutant cannot be completely removed in other processes. The degradation rate was calculated by the following formula:

$$\text{Elimination rate} = \frac{\text{concentration(initial)} - \text{concentration (treated)}}{\text{concentration (initial)}}$$

3.3 Effects of and hydrogen peroxide（30%）

In order to investigate the role of H_2O_2 in removing RhB from the aqueous solution, 5 mL H_2O_2 were added to 150ml solutions of RhB, respectively, to study the RhB degradation behavior. Fig. 4 indicates the elimanation rate of the RhB in the presence of H_2O_2 at reaction time 120 minutes. The results show that the removal efficiency of RhB with hydrogen peroxide is higher than without hydrogen peroxide. It may be explained that the concentration of HO· is increased when H_2O_2 was added into the RhB solution and hydroxyl radical is the most responsible oxidant in the degradation of RhB.

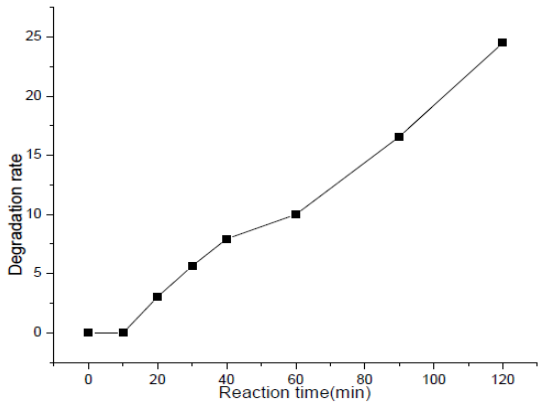

Fig. 4. Accelerating effect of H_2O_2 on RhB degradation

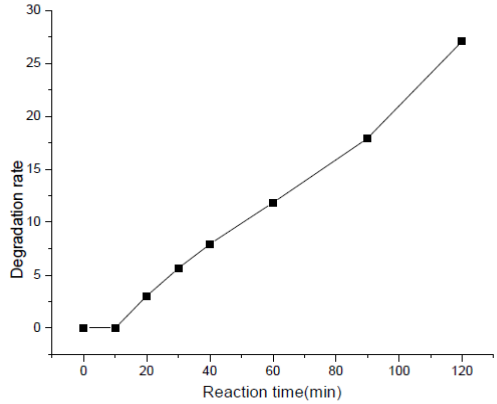

Fig. 5. Effects of ferrous sulfate（0.4mL10% Fe^{2+}）

3.4 Effects of ferrous sulfate

Fig.5 shows the removals of RhB in the presence of ferrous sulfateduring 120 minutes of treatment. The results show that Fe^{2+} has a obvious catalytic effect for RhB degradation. The rapid increase in the reaction rate upon the addition of $FeSO_4$ may be attributed to the Fenton's reaction. In the presence of Fe^{2+}, the H_2O_2 produced by the discharge was converted to ·OH again, thus accelerating the degradation velocity [17-18]. Therefore, the amounts of hydroxyl radicals which are available for the reaction with RhB.

3.5 pH Effects

Special attention was paid to investigate the effects of solution pH on RhB degradation, since the pH often plays an important role in the wastewater treatment. Fig.5 shows the results of a series of experiments at different pH. Faster RhB removal rate can be obtained in a relatively higher acidity than in neutral conditions and alkalinity. This maybe presumed that more ·OH was produced in CGDE under acidity conditions. Because a lot of industrial wastewater is acidic, the treatment of wastewater does not need pH adjustment in the plasma process.

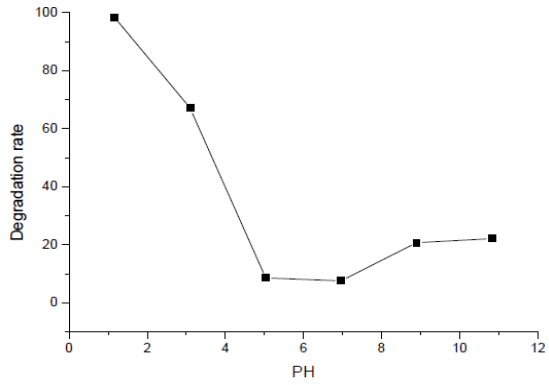

Fig. 6. Effects of pH on RhB removal

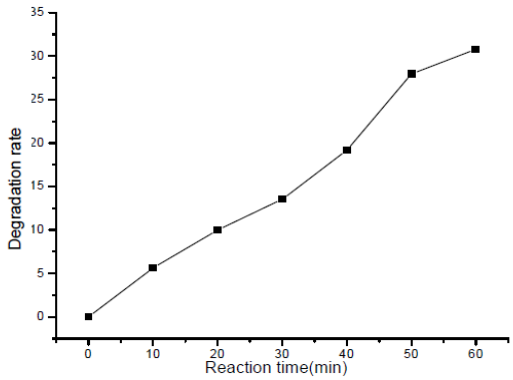

Fig.7. Effects of n-butanal(0.4mL)

3.6 Effects of n-butanol

Fig.6 shows the removals of RhB in the presence of n-butanol during 60 minutes of treatment. The results show that n-butanol has a strong inhibition effect on RhB degradation. As well known that n-butanol reacts with hydroxyl radical with a high rate constant (10^8 L·mol^{-1}·s^{-1} [4]). Therefore, the amounts of hydroxyl radicals that are available for the reaction with RhB are lower in the presence of n-butanol than those without n-butanol.

3.7 Intermediate products

For better understanding the degradation mechanism, HPLC and GC-MS were used to determine the intermediate products formed during degradation process. The major intermediate products identified by GC-MS were benzoic acid, paradioxybenzene, benzoquinone, benzene and some other products. As the treatment went on, some carboxylic acids such as formic, oxalic and malonic acids etc. were formed. In the end, all of the carboxylic acids were decomposed to inorganic carbon, which might exist as bicarbonate or carbon dioxide.

4. Conclusion

RhB can be rapidly and exhaustively degraded by glow discharge electrolysis under water. The final products were inorganic carbon and inorganic nitrogen. Faster RhB removal rate can be achieved in relatively higher acidity. The degradation can be greatly accelerated in the presence of Fe^{2+} ion and H_2O_2 and can be inhibited in the presence of *n*-butanol. All the experimental results show that the hydroxyl radicals are the most responsible oxidants for RhB degradation in glow discharge electrolysis under water. Therefore, glow discharge electrolysis under water is an efficient method for RhB degradation.

The preparation of ZnO: Al thin films on flexible substrates by magnetron sputtering method

Wang XiaoJing

College of electronics & information engineering, Wuhan Textile University ,Wuhan 430074,China

wxjisme@126.com

Keywords: ZnO:Al; Magnetron Sputtering; Buffer layer;Structure and properties

Abstract. ZnO: Al film was deposited on TPT substrate with SiO_2 buffer layer by RF magnetron sputtering. The obtained film had a hexagonal structure and highly (002) preferred orientation. The lattice constant distortion of the film with buffer layer was decreased and the compressive stress was 0.779GPa. The carrier concentratio reached to $3.15\times10^{+20}$/cm3. The resistivity of ZAO film with SiO_2 buffer layer was about 9.2×10^{-3} Ω·cm and the average transmittance was over 72% in the range of 380~900nm.

Introduction

ZnO: Al (ZAO) transparent conductive thin films on flexible substrates are a hot subject of research for their special advantages including light weight, easy bending and resistant to impact damage [1-2], which are important for the applications in some devices such as flexible solar cells and flexible touch screens. ZAO thin films on some flexible materials are almost deposited at low temperature（ < 200℃）due to the poor high-temperature characteristics of these flexible substrates, including PET [3], PC [4], PI [5], PPA [6], Teflon [7], PES[8] and so on. Since the resistivities of ZAO films on flexible substrates are high, in the quantity of 10^{-2}~10^{-3}Ω·cm[9-10], they need to be improved especially for the industrial application in solar cells and other devices. There are several methods to improve the conductivity of ZAO films, such as increasing the film thickness, adjusting the deposition parameters , adopting a buffer layer between the flexible substrate and the ZAO films . The last one is an effective way to improve the conductivity of the ZAO films and will not be damaged to the optical properties of the films. Various kinds of buffer layers have been introduced in ZnO film growth, such as ZnO[11], Al_2O_3[12] , MgO[13] and SiOx[14].

The deposition of ZAO films on transparent TPT substrates by RF Magnetron Sputtering method has been successfully prepared by our group [15].In this paper, we reported the preparation of high conductivity of ZAO thin film on transparent TPT substrate by introducing a SiO_2 buffer layer and studied the influence of buffer layer on the structural, optical and electrical properties of AZO films.

Experimental procedure

The ZAO thin films were deposited on transparent TPT substrate by RF magnetron sputtering system from a ZnO: 2.0 wt % Al_2O_3 target (purity: 99.99%). The substrate with thickness of 50μm was ultrasonically cleaned in acetone and then in ethanol for 15 min respectively before it was loading into the deposition chamber. The distance between the target and substrate was about 50 mm. Before the deposition of ZAO thin films, SiO_2 buffer layers were deposited using a SiO_2 target (purity: 99.99%) by RF magnetron sputtering at room temperature with 0.5 Pa of deposition pressure and 300W of RF power. For the purpose of comparison, the ZAO films without buffer layers were also deposited on TPT substrates. The ZAO films were grown at room temperature (about 25℃) for 180 min with the flow rate of Ar of 20 sccm, the deposition pressure of 1.0 Pa and the RF sputtering power of 120 W.

The structure properties and surface compositions of the ZAO films were analyzed with X-ray diffraction (XRD, X'Pert PRO, λ=0.154 nm) using Cu-Kα radiation and field-emission scanning electron microscopy (FE-SEM, Sirion 200) . The transmittances of the films were measured by spectrophotometer (UV, Lambda 35) in the range of 380~900 nm and the electrical properties were characterized by a Hall Effect Measurement System (Lakeshore MODEL 642) at room temperature.

Results and discussions

Structure properties

Fig.1 shows XRD patterns of ZAO films. The ZAO film without buffer layer had a diffraction peak at 2θ about 34.22° and the film with SiO_2 layer had a diffraction peak at 2θ about 34.25°, which is associated with the (002) plane of hexagonal phase ZnO and implied that the prepared films had a c-axis preferred orientation. The average grain sizes were derived by Scherrer equations as follows:

$$D = \frac{0.9\lambda}{\beta \cos\theta} \tag{1}$$

where λ is the X-ray wavelength (0.154 nm), θ is the Bragg angle, and β is the FWHM of the (002) diffraction peak. The grain size of ZAO film is 68.26nm for sample without buffer layer and 60.15nm for those with buffer layer.

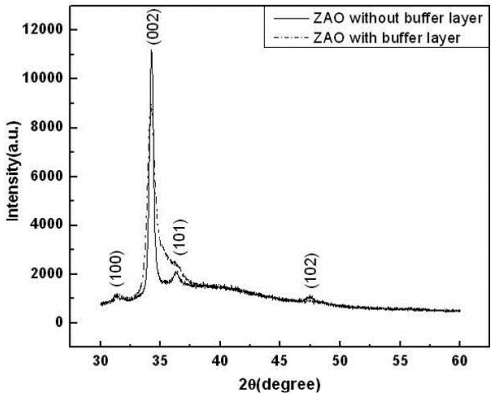

Fig.1. XRD patterns of ZAO thin films

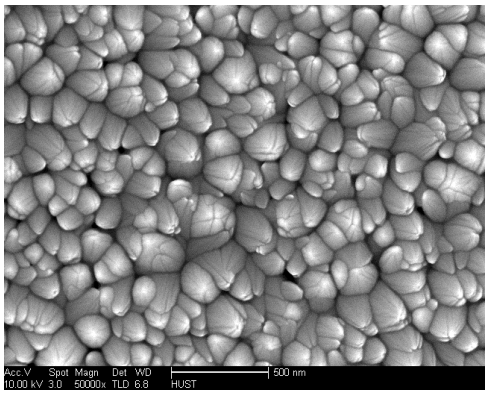

Fig. 2. SEM images of ZAO thin films with SiO_2 buffer layer

The SEM image of theZAO thin film was shown in Fig. 2. It was observed that the ZAO films consisted of some columnar structured grains. The ZAO film was compact. The deposition rate of the ZAO film with buffer layer was about 5.4nm/min.

The strain along c-axis orientation was derived by the formula [16]:

$$\varepsilon_{zz} = \frac{c - c_0}{c_0} \times 100\% \tag{2}$$

where c is lattice constant calculated from XRD result, c_0 (0.521nm) is unstrained lattice constant measured from ZnO powder. The stress parallel to the ZAO film surface was calculated by the following formula [17] :

$$\sigma_{film} = \frac{2c_{13}^2 - c_{33}(c_{11} + c_{12})}{2C_{13}} \times \frac{c_{film} - c_0}{c_0}, \tag{3}$$

where c_{ij} is elastic constants， the data have been used : c_{11} =208.8, c_{33} =213.8, c_{12} =119.7, c_{13} =104.2GPa. The stress in the film with buffer layer is -0.654GPa, where negative sign corresponds to compressive stress. These may be due to the following two reasons : one is intrinsic stress caused by impurities and defects; the other is thermal expansion coefficient mismatch between the film and the substrate.

Electrical properties

The electrical properties of the ZAO films were measured by Hall Effect Measurement System. The lowest resistivity was $9.2\times10^{-3}\Omega\cdot$cm with a carrier concentration of $3.15\times10^{+20}/cm^3$ and hall mobility of $3.5cm^2/(VS)$.

Optical properties

Fig. 3 shows the optical transmittances of the ZAO films including the TPT substrates. It was seen that the transmittances of the ZAO films on TPT substrates were over 65% in the visible region, and the average transmittances of the two films were over 72% in the range of 380~900nm. The absorption edge of the ZAO film with buffer layer was shifted to the higher energy. It is attributed to the Burstein-Moss effect [30], which is the blue shift of the absorption edge with increasing carrier concentration. The transmittance of the ZAO film with buffer layer was a little higher than that of the film without buffer layer. It is mainly because that the latter was thicker than the former at different film deposition rate.

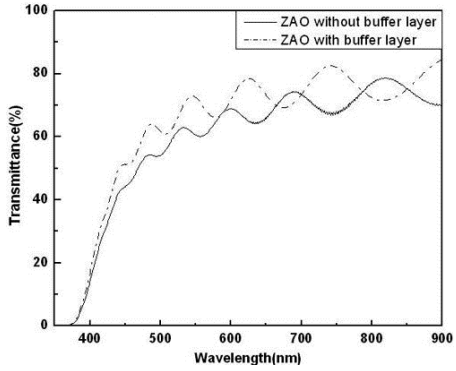

Fig. 3. Transmittance curves of ZAO thin films on TPT substrates

Conclusions

ZAO thin films with SiO_2 buffer layer were prepared on TPT substrate by magnetron sputtering. XRD and SEM measurements revealed that the films were highly c-axis oriented. The resistivity of ZAO film with SiO_2 buffer layer was $9.2\times10^{-3}\ \Omega\cdot$cm with a carrier concentration $3.15\times10^{+20}/cm^3$. The optical transmittance of the ZAO film was over 72% in the range of 380~ 900nm.

Keywords: Screw; device clamp; fracture; transmission line.

Abstract. Fracture failure analysis on device clamp screws of one 110kV transmission line has been carried out based on results of macro-observation, pre-tightening test, mechanical property examination, chemical composition analysis, microstructure observation, SEM observation and EDAX analysis. It is concluded that the main reason of the screw fracture lies in misuse material and improper heat processing which led to material degradation. Suggestions are put forward finally.

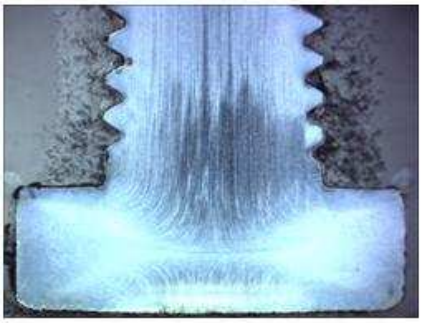
Introduction

Device clamp was a kind of connection fitting used to fix mother conductor and terminal outgoing. As one of power fittings, device clamp plays an important role in guaranteeing safe and stable operation of high and super high voltage transmission lines [1] [2]. Device clamp failure will cause severe electric network accidents and failure analysis is necessary and instructive to avoid similar events [3] [4] [5].

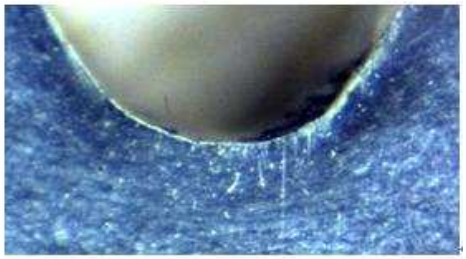
The failure causes of device clamp of one 110kV transmission line were discussed in this paper and measurements were provided. The failure crack happened to the strain clamp on A-phase of 158-5 knife switch whose screws cracked, and overheating temperature was as high as 360^{o}C under 80A electric current. The screw dimension was M10 and its material was austenite stainless steel with minimum tensile strength of 700MPa according to GB/T 3098.6-2000.

Experimental Observation and Analysis

The dimension of the screw was measured to be M10. It can be consumed that the screw was processed by upset forging according to the metal flow in the screw section and the thread was processed by squeezing as shown in Fig.1 (a) and (b).



(a)The metal flow in the screw section



(b)The metal flow in the screw end

Fig.1 The macro morphology of the metal flow in the screw

The fracture morphology of the failure screw was observed by stereomicroscope. Old fracture section was found in the fresh fracture, meaning that crack defect had existed before the screw fracture. The morphology was shown in Fig.2.

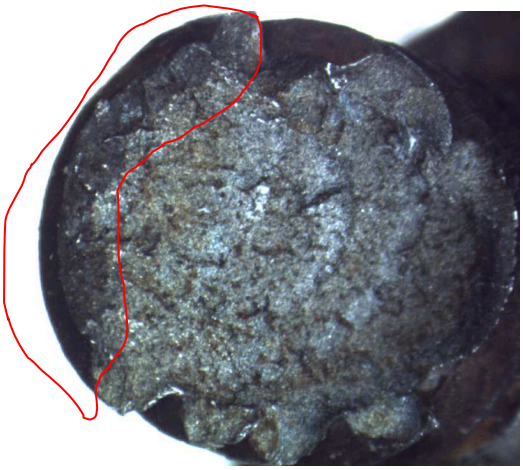


Fig.2 The origin defect in the screw fracture

The unbroken screw was fastened on the test table and the test was carried out by torque wrench and load measurement equipment. When the single nut was pre-tightened, the thread was easily damaged due to the engagement between screw and led to nut slippage as shown in Fig.3. During the pre-tightening test for single screw, the phenomenon happened twice with driving torque of 60Nm and pre-tightening load of 885N which far below fracture load, meaning that nut tightening was impossible to result in screw broken.

Fig.3 The engagement area between screw and nut

The pre-tightening test result was given in table.1.

Table.1 Pre-tightening test result of the unbroken screw

Serial number	Torque(Nm)	Voltage of sensor(V)	Pretightening load(N)	Remarks
1	40	0.256	796.4	/
2	60	0.281	885.7	Thread cracking noise
3	70	0.296	939.3	Thread slippage

The result of mechanical properties test was illustrated in table.2 it can be found that the tensile stress of the screw meet the standard for A2-70 stainless steel of 700MPa,, whereas its percentage elongation after fracture was lower than the standard requirement of 4mm. Therefore, the mechanical properties of the tested screws didn't accord with the relevant standard requirement.

Table.2 The mechanical properties of the screws

Sample number	Original length(mm)	Length after fracture(mm)	Elongation after fracture(mm)	Maximum tensile load(N)	Tensile stress(MPa)
1	49.9	52.8	2.9	51.22	883
2	49.8	52.8	3	53.55	923
3	49.8	50.8	1	46.68	805

In addition, original crack was found at the end of the screw of sample 3 as indicated in Fig.4 that showed the process of these screws was improper.

Fig.4 The original defect on the tensile fracture pf the screw(circled area by the red line)

The chemical composition of the screw was analyzed by ARL 3460 direct-reading spectrometer in order to examine the material. The result was given in table.3.

Table.3 The result of chemical composition analysis of the screw

Element	C	Si	Mn	S	P	Cr	Ni	V	Cu
Mass percentage(%)	0.03	0.43	17.93	0.012	0.061	7.07	0.12	0.01	0.16

It can be seen from table.3 that the material was not austenite stainless steel but that substitued Ni by Mn. Therefore the material doesn't meet with the requirement of GB/T 3098.6-2000 for A2-70 stainless steel(C<0.1%,Si<1%,Mn<2%,P<0.05%,S<0.03%,Cr=15~20%,Ni=8~19%,Cu<4%).

The microstructure of the screw was illustrated in Fig.5. It can be found to be austenite microstructure.

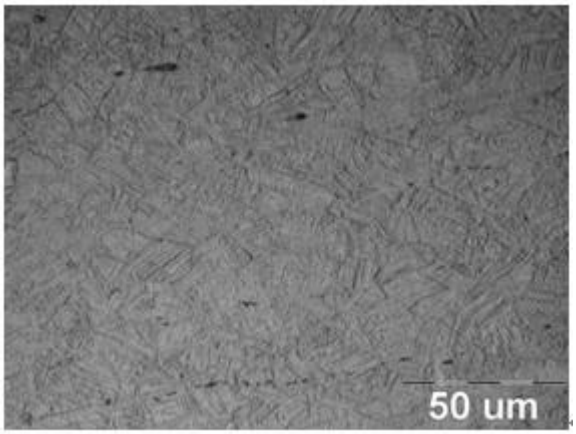

Fig.5 Metallurgical microstructure of the screw

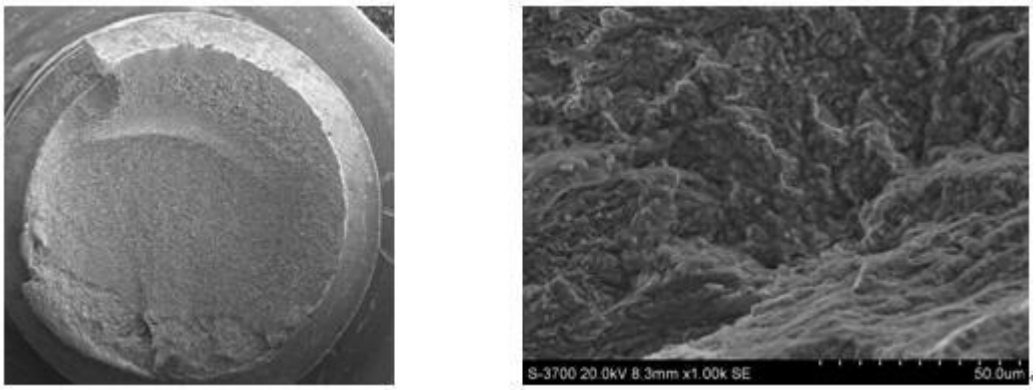
The original crack of the screw fracture was observed by SEM and it was seen thick oxides covered there as shown in Fig.6 (a) and (b).



(a) SEM of the failure screw fracture (b) Thick oxides on the original crack area

Fig.6 SEM morphology of thick oxides covering the original crack area

EDS analysis examined high quantity sulfur whereas no element usually contained in water such as Cl, Na, Ca as shown in Fig.7 and table.3.

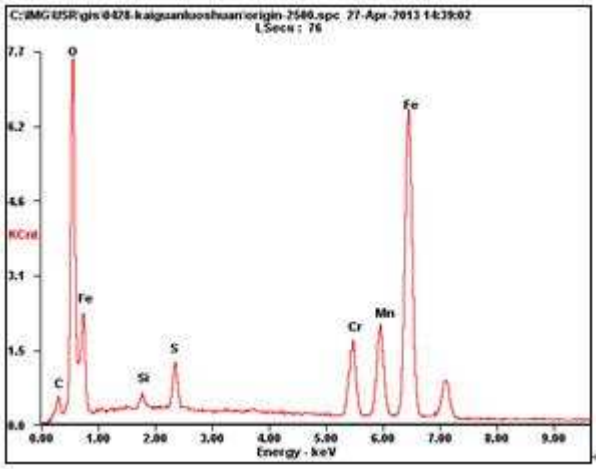


Fig.7 EDS analysis of the original crack fracture

Table.3 EDS quantity analysis result of original crack area

Element	C	O	Si	S	Cr	Mn	Fe
Mass percentage(%)	0.05	24.15	0.83	2.34	7.48	11.92	53.24

In addition, SEM observation on the fracture of crack propagation area exhibited characteristics of dimple fracture shown in Fig.8.

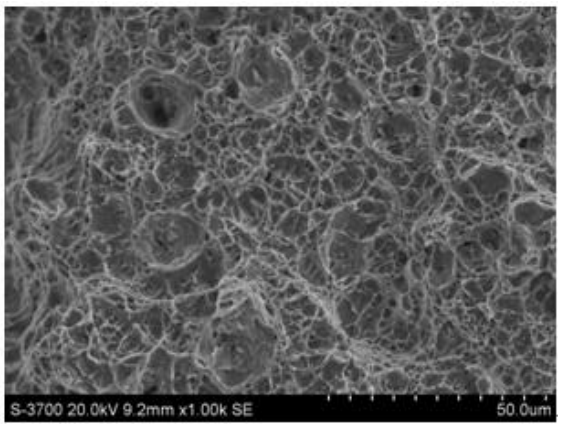

Fig.8 SEM of dimple fracture of crack propagation area

The fracture screw remained on the apparatus was examined by SEM and it was also found there existed old crack, and the fresh fracture was characterized by intergranular fracture as illustrated in Fig.9.

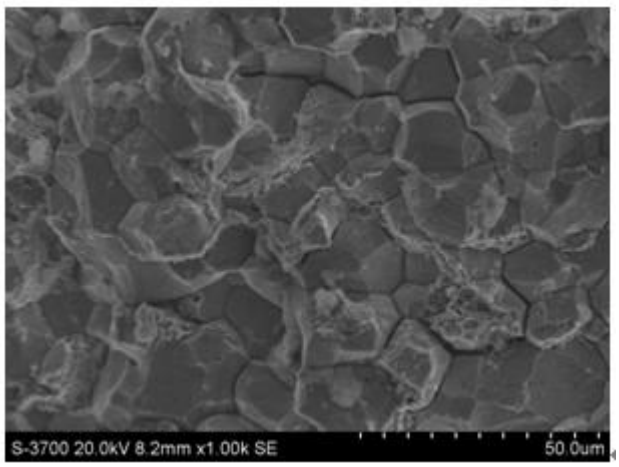

Fig.9 SEM fracture of the broken screw remained on the apparatus

Discussion

Macro-observation showed that the pre-tightening load of single screw was far below its fracture load, so the old fracture was not due to over-high pre-tightening load. Neither mechanical properties nor chemical composition met with the requirement of relevant standards. Although sulfur was examined in original crack area, no features of stress corrosion being found and compressive stress due to squeezing processing denied the possibility of stress corrosion. All the failure screws expressed characteristics of inter-granular crack the screw except old crack area, meaning that the improper heat treatment was carried out or temper brittleness happened during the subsequent processing.

Conclusion and Suggestion

Misuse of material and improper hardworking process contributed to the screw failure. It was suggested the screws be replaced and acceptance inspection be carried out on the new screws to ensure their qualification.

Keywords: Laminate; Ply thickness; Dynamic Response; Low-velocity Impact

Abstract. Based on the two-dimensional Hashin failure criteria and the introduction of material degradation damage factor, low-speed impact model of composite laminated plate was established by ABAQUS with fiber and matrix's failure modes being taken into consideration. The mode is verified by referring to Karakuzu test. Next, it analyzes single ply thickness' effect on laminated plate's response and damaged under low-velocity impact. The result shows that with the thickness increasing, impact contact time and laminated plate impact point's deflection displacement reduce, while the impact force and volatile shocks are more obvious.

Introduction

Composite laminated plate with excellent mechanical properties, has been widely applied in aerospace and ship, etc. Laminated plates in low-velocity impact injury prone to failure under the action of the internal material to induce the degradation of its mechanical performance, reduces the safety of the structure. Research that aimed at low-velocity impact damage characteristics of laminated plates, domestic and foreign scholars have done much work in both experiment and numerical simulation. Through the work of Moura [1], damage prediction of the carbon/epoxy laminated plates under low-velocity impact was carried out with experimental and numerical method, the numerical results of degradation damage shape and distribution direction are in good agreement with the experiment. Low-velocity impact test and numerical simulation of the laminated plates were done by Choi [2], etc, the relationship between matrix failure and layered is analyzed. Researchers considered that the impact of the laminated plates' initial damage form is the matrix failure. Shi [3], etc, had studied the damage of laminated plates under different impact speed by establishing a 3D model, the model accorded with the Hashin failure criterion based on stress and uses cohesive unit to simulate the stratified, and Shi also analyzed the differences of numerical and experimental results. By using finite element method, Wu [4] regarded the low-velocity impact process as a reference and investigated the interference of medium plate under low-velocity impact of composite material plate with SMA volume effect on shock response of the situation. So Wu deemed that if the content of SMA volume increase, low-velocity impact damage resistance of the composite material plate would improve. Low-velocity impact model was established and the laminated plate impact damage factors was analyzed by Fuoss [5], finding the maximum impact plays a bigger role, however, the model stiffness degradation failure caused by material was not took into account, gradually leading to the bias between numerical results and experimental results. Karakuzu [6] carried out the low-velocity impact test of glass fiber/epoxy resin composite material, analyzed tha impact damage characteristics of composite material plate under different impact energy, quality, speed, and established three-dimensional model for numerical simulation, the results are agreed with the experimental results. Referring to Karakuzu's experiment, this work is based on the Hashin failure criterion and introduces the material degradation damage factor, uses

ABAQUS to establish two-dimensional composite laminated plate's low-velocity impact model, tests and verifies the rationality of the model, finishes the related impact numerical simulation by using the model, provides relevant basis and conclusion as reference for the engineering application of composite laminated plate.

Material Failure Criterion

Among failure criteria of composite laminated plate's ply, maximum stress theory, maximum strain theory, rule of Tsai-Hill, Hoffman criteria, Tsai-Wu tensor rule are commonly used. Because the material failure mode and mechanism of the criterion is not added to the material failure conditions, these criteria have nothing to do with the pattern of rule. Ignoring the stress between the middle laminated plate failure process and considering the failure modes and mechanism of material, the rule of two-dimensional Hashin process is applied to determining the damage impact on laminated plates, and its expression is shown in table 1. Type: σ_1, σ_2, τ_{12} are the normal stress and shear stress of composite laminated plate's ply; X_t and X_c are the ply's longitudinal tensile and compression strength; Y_t and Y_c are the ply's transverse tensile and compression strength; S_{12} is shear strength of the ply on direction 1-2.

Tab.1. Hashin failure criteria

Failure mode	expression
Fiber tensile failure	$\left(\frac{\sigma_1}{X_t}\right)^2+\left(\frac{\tau_{12}}{S_{12}}\right)^2\geq 1 \quad \sigma_1\geq 0$
Fiber compression fracture	$\left(\frac{\sigma_1}{X_c}\right)^2\geq 1 \quad \sigma_1\leq 0$
Substrate tensile or shear failure	$\left(\frac{\sigma_2}{Y_t}\right)^2+\left(\frac{\tau_{12}}{S_{12}}\right)^2\geq 1 \quad \sigma_2\geq 0$
Matrix compression or shear failure	$\left(\frac{\sigma_2}{Y_c}\right)^2+\left(\frac{\tau_{12}}{S_{12}}\right)^2\geq 1 \quad \sigma_2\geq 0$

Material Degradation Rule and Unit Removing

In the process of low-velocity impact, once the unit stress in the laminated plates meets one of the failure criteria in table 1, failure of materials will lead to the performance deterioration. Accordingly, the rigidity of unit's material should be reduced. The model is using the material degradation form of ABAQUS software [7].By introducing a simple linear elastic model based on energy, when the accumulation of material damage energy meets the initial damage threshold and attains to destructive critical threshold (breaking energy), material will reduce along with stress-strain relationship curve of the linear softened definition, in material damage evolution stage.

Materials are set as linear elastic before the initial damage does no happen. After damage, material constitutive relation is as follows:

$$\sigma = C_d\varepsilon \tag{1}$$

In the type(1): ε is strain for material. Damage stiffness matrix representation C_d is as follows:

$$C_d=\begin{bmatrix}(1-d_f)E_1 & (1-d_f)(1-d_m)E_1 & 0\\ (1-d_f)(1-d_m)E_2 & (1-d_m)E_2 & 0\\ 0 & 0 & (1-d_s)GD\end{bmatrix} \tag{2}$$

In the type(2): $D=1-(1-d_f)(1-d_m)\nu_{12}\nu_{21}$. d_f, d_m, d_s are variables of fiber, matrix, the shear damage under the current status respectively. d_f, d_m, d_s are gained from Hashin damage variables of four damage modes, the concrete expressions are as follows:

$$d_f=\begin{cases}d_f^{\,t} & (\hat{\sigma}_{11}>0)\\ d_f^{\,c} & (\hat{\sigma}_{22}<0)\end{cases} \tag{3}$$

$$d_m = \begin{cases} d_m{}^t & (\hat{\sigma}_{22} > 0) \\ d_m{}^c & (\hat{\sigma}_{22} < 0) \end{cases} \tag{4}$$

$$d_s = 1-(1-d_f{}^t)(1-d_f{}^c)(1-d_m{}^t)(1-d_m{}^c) \tag{5}$$

In the process of low-velocity impact, if both fiber and matrix of a unit within a ply lost bearing capacity, it means that the ply is broken and that unit should be removed from the model.

The Establishment of the Model

Referring to the test of Karakuzu, laminated board size is 76.2mm×76.2mm. Thickness of a single ply: d_0=0.36mm, a total of 8 layers. Ply in the form: [0°/30°/60°/90°]s. Composite laminated plate material parameters and mechanical performance parameters are shown in table 2 and 3. Finite element analysis software ABAQUS is used to analyze the composite laminated plate's low-velocity impact mode. Since the ratio of laminated plate's width and thin is more than 10, it's a thin-walled structure. Then laminated plate is described as a 4 nodes first-order reduced integral shell unit (S4R) with an control hourglass, and the influence of shear deformation is took into consideration, so the computer can obtain higher accuracy of the results while saving calculating cost. Considering the more violent grid deformation of impact center during impact, the center regional grid is refined in meshing phase to improve the calculation accuracy. The center grid size is 1 mm×1 mm, mesh size's transition between center regional and border area guarantees the quality of the grid and reduces the computing time. Laminated plate's boundary setting refers to Karakuzu test, bordering around the ground constraints, which restrict only three direction of the displacement of edges and not restrict rotational degree of freedom.

Tab.2. Mechanical properties of the composite laminate

ρ (g/cm^3)	E_{11} (GPa)	E_{22} (GPa)	G_{12} (GPa)	v_{12}
1.83	40.51	13.96	3.10	0.22

Tab.3. Mechanical properties of the composite laminate

X_T (MPa)	X_C (MPa)	Y_T (MPa)	Y_C (MPa)	S_1 (MPa)	S_{12} (GPa)
783.30	298.00	64.00	124.00	38.00	69.00

The punch model is 12.7 mm steel hemispherical punch. The simulation aims mainly at investigating the dynamic response of the impact process and damage evolution characteristics, moreover, the stiffness of the punch is much bigger than laminated plate's, so the unit type is two-dimensional analytical rigid body without considering deformation of the punch. By setting reference point and exerting quality and speed on the reference point according to the formula $E=mv^2/2$, punch head is imposed with impact energy. The contact between the punch and laminated plate is hard contact and it can cause contact element failure, so the ordinary hard contact algorithm is adopted. Composite laminated plate low-velocity impact finite element model is set up as shown in figure1.

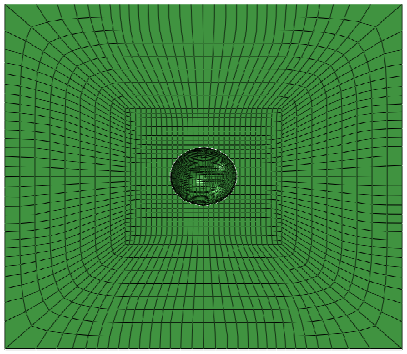

Fig.1. FEM model of composite laminates

The Model Validation

Referring to the test, 5 test cases are selected: 5kg-10J, 5kg-20J, 5kg-30J, 10kg-20J, 15kg-30J, respectively mark as impact conditions 1, 2, 3, 4, 5, that are divided into two groups: the same impact velocity and the same impact quality, and finish laminated plates low-velocity impact numerical simulation. The parameters of working conditions shows in table 4.

Tab.4. Different impact test cases

Impact energy	Under the same impact velocity (2m/s) the impact of the quality/kg	Under the same impact mass (5 kg) of impact velocity/(m/s)
10	5	2
20	10	2.828
30	15	3.464

In order to verify the correctness of the finite element model of low-velocity impact, comparison results under various impact conditions in this paper is given. figure 2 shows impulse response processing curves of numerical simulation, the experimental value and Karakuzu numerical simulation.

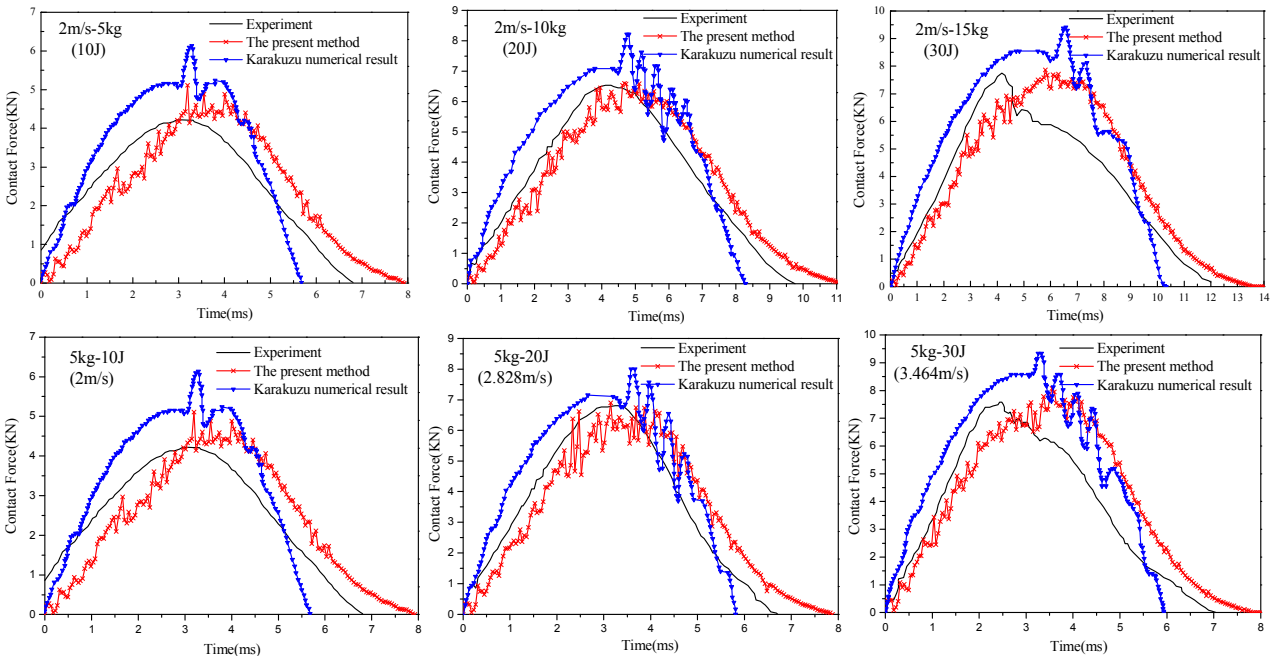

Fig.2. Comparison of impact force-time curves

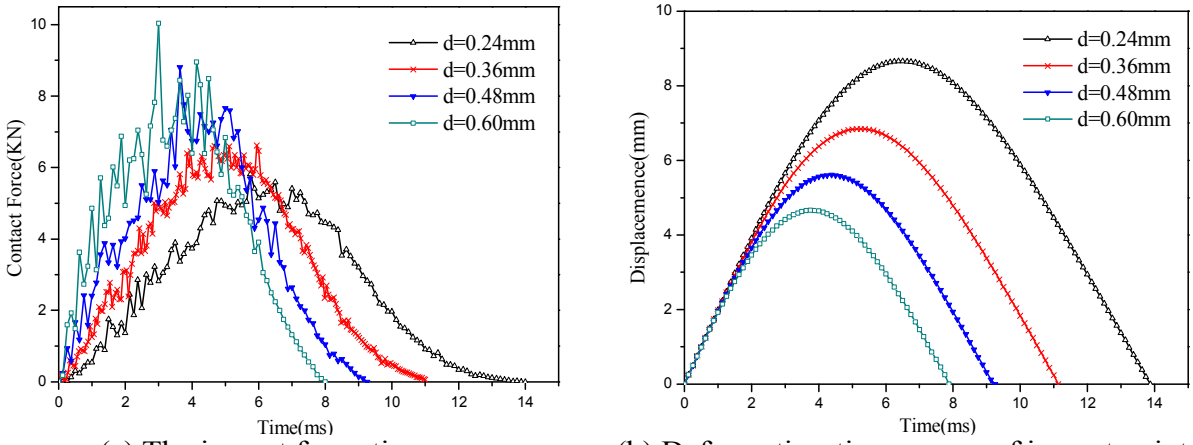
Ply Thickness' Effect on Shock Response

In the optimization design of the composite material plate performance, in order to avoid the waste of material and maintain specific intensity and specific stiffness properties of the laminated plates, ply should not be too thick. And the thickness of laminated plates should not be too thin to keep the compressive strength, so the selection of ply thickness is very important.

Under impact condition 4, the ply thickness' influence on impact damage properties is explored by changing the ply thickness d_0. Shock responses of laminated plates ply with thickness of 0.12 mm, 0.24 mm, 0.36 mm, 0.48 mm, 0.60 mm are investigated. When d_0=0.12mm the thickness is too thin to offer sufficient strength. Then deformation of laminated plate's impact area is too large in impact process, the compressive failure damage of spreading layer's fiber and material occurs, so laminated plate is not able to resist impact of the punch. Figure 3 shows the impact-time curves of the other four sets' layer thickness. As shown in the diagram, when d_0=0.24mm, impact rises gradually and reduces gradually to zero after meeting the peak, and there is an obvious bending deformation on laminated plate impact area. As the layer thickness of laminated increase, ensemble strength of plate increases, resistance to shock increases while impact contact time decreases, and the impact increases, the impact amplitude fluctuation also increase gradually.



(a) The impact force-time curves (b) Deformation-time curves of impact point

Fig.3. The numerical results

Conclusion

Based on the two-dimensional Hashin failure criteria and the introduction of material degradation damage factor, low-velocity impact model of composite laminated plate was established by ABAQUS. After the accuracy of laminated plates model's impact dynamic response and damaged under low-velocity are verified, a thorough research of the ply thickness' effect on the impact response under low-velocity is carried out. The result shows that and laminated plate overall strength is not enough to resist impact if ply thickness is too thin, and with the thickness increasing, impact contact time and laminated plate impact point's deflection displacement reduce, while the impact force and volatile shocks are more obvious.

Study on the Synthesis of Ethylene Glycol by Catalytic Hydrolyze of Ethylene Carbonate

Min Zhang[1, a]

[1]Secondary College of Textile and Dye Engineering, Nantong Textile Vocational Technology College, Nantong, 226007, China

[a] zhangmin@nttec.edu.cn

Keywords: Ethylene carbonate; Catalytic hydrolyze; Ethylene glycol; Water ratio.

Abstract. The process for ethylene glycol (EG) by catalytic hydrolysis of ethylene carbonate (EC) was studied. The influencing factors of the reaction products were studied which include the reaction temperature, the mole ratio of H_2O to EC, the mass fraction of the catalyst and the reaction time. The optimal conditions were identified as follows: the reaction temperature is 140-145℃, n(H_2O) :n(EC) = 2.0-2.5 : 1, the catalyst of Al_2O_3 is about 2.0wt%, the reaction time is about two hours. Under the above conditions, EC can be completely hydrolyzed and the selectivity of EG is above 98%.

Introduction

Ethylene glycol (abbr. EG) is an important organic chemical material. It is widely used to produce antifreeze agent, polyester fiber, lubricants, unsaturated polyester resin, explosives and non-ionic surfactants etc. . In recent years, the total demand of ethylene is rising gradually in the world, it has become the third large variety of series products of ethylene after polyethylene, polyvinyl chloride (PVC). [1]

At this stage, the large-scale industrial production of ethylene glycol adopts the direct hydration method of ethylene oxide (abbr. EO), the disadvantages of this process mainly includes as follows: the mole ratio of H_2O to EO is very high, the process flow is longer, the selectivity of MEG is lower. In the process the energy consumption of the devices is more, the most of the energy is used to evaporate water of the products [2, 3]. In recent years, in order to improve the selectivity of the end product EG and reduce energy consumption, the researchers have constantly developed new EG synthesis processes, the new processes are mainly catalytic hydration of EO, the process of ethylene carbonate (EC), the syngas method and formaldehyde or methanol synthesis method, etc. The process of catalytic hydrolyze of ethylene carbonate among them is considered to be one of the promising methods of industrialization, because it has many advantages including the higher selectivity of EG, the lower mole ratio of water to EC (hereinafter referred to as water ratio) , mild reaction condition, lower energy consumption, Less investment and so on[4]. Now the companies which have much deeper research on the method are mainly American Halcon-SD, Nippon Shokubai, Mitsubishi Chemical Corporation, Japan. The difference lies primarily in the choice of catalyst among the research process of three companies.

The synthesis process of ethylene glycol by catalytic hydrolyze of ethylene carbonate mainly consists of two steps, esterification and hydrolysis. In the two reactions above, the first step is the synthesis of EC by the reaction of carbon dioxide with ethylene oxide under the action of catalyst. The second step is the synthesis of EG by the catalytic hydrolysis of EC. And the research on the first esterifiable process is fairly mature and it has been industrialized, but study on the second hydrolyzed research is still not successful. This paper is just researching for synthesis of EG by catalytic hydrolysis of EC as material.

In recent years, domestic Nanjing University of Technology has been engaged in related research for the second step hydrolysis reaction. This paper is based on the previous studies[5,6] to further optimize the reaction conditions for EG synthesis process by this method, active aluminum oxide has been chose as catalyst, The influence of reaction factors such as reaction temperature, water ratio,

catalyst dosage, reaction time has been investigated and the optimal reaction conditions have been obtained.

Experiment Part

Raw Materials and Main Equipments

Ethylene carbonate, no less than 99.5%, Nantong Merck chemicals co., LTD. Ethylene glycol, AR, Shanghai Ling Feng chemical reagents co., LTD. Activated alumina γ -Al_2O_3. Three-necks flask, 250 mL. Type of WT – 100B temperature programmed controller, plant of southeast university. Analytical balance, Shanghai Jingke co., LTD. Type of SP-6801 GC, Shandong Lunan Ruihong chemical instruments co., LTD.

Analysis Conditions and Analysis Methods of Gas Chromatographic

Analysis conditions of gas chromatographic are as follows : the column is a stainless steel packed column whose length is 2 meters, diameter is 4 mm x 1 mm, packing inside is GDX-103. carrier gas is H_2, the pressure before the column is 0.06 MPa, thermal conductivity cell detector, bridge flow is 125 mA, gasification chamber temperature is 250℃, the detector temperature is 250℃, column temperature is 220 ℃, sample size is 1.0 μL.

Analysis methods are as follows: product qualitative analysis is carried out by the comparison with standard substance. The different solubility standard solutions are analyzed by GC, and relative mass correction factor of each composition are calculated, and then the conversion of EC and selectivity of EG are calculated by the area normalization method.

Determination of Relative Mass Correction Factor

The quantitative analysis of GC is done by the proportion of weight of each composition or concentration in the carrier gas to the detector response value, and because the same detector has different response value with different material, the peak areas measured are often not equal with the same amount of two different materials. So the correction factor is required to add. Relative mass correction factors of various compositions are determined and shown in the following table in this experiment.

Table1. Relative mass correction factor of several chemicals

Chemicals	H_2O	EG	DEG	EC
f_m'	1.000	2.003	2.087	2.466

Results and Discussion

Effect of Reaction Temperature

Reaction conditions: water ratio is 2.0, the dosage of catalyst is 2% of the total amount of EC and water (by mass, the same below), reaction time is 2h. According to EC 44g, H_2O 18g, Al_2O_3 catalyst 1.25g, reaction time 2 hours in each experiment, the effects of different reaction temperature on the reaction product are discussed, the experimental results are shown as Fig.2.

Fig. 2 shows, when temperature is 120 ℃, the conversion rate of EC is only 55%, when the temperature is higher than 140 ℃, the conversion rate of EC reaches 100%. And when the temperature is higher than 140 ℃, the selectivity of EG will decrease. When the temperature rises to 170 ℃, the selectivity of EG reduced to 90%. This is mainly due to acceleration of the decomposition rate of EC[7]. When temperature is higher than 150 ℃, EO produced by the decomposition of EC and EG will continue reaction to transform into diethylene glycol. Therefore, in the process the reaction temperature should be controlled in 140-145 ℃, and keep stirring to avoid increase of the decomposition of EC because of over-high local temperature.

Effect of Water Ratio

Reaction conditions: According to reaction temperature 140℃, the dosage of catalyst 2%, reaction time 2h, the effects of different water ratios on the reaction product are discussed. The experimental results are shown as Fig. 3.

Fig.3 shows, when water ratio is 2.0 or higher, conversion of EC and selectivity of EG are both 100%, but energy consumption will increase with the increase of water ratio. When the water ratio is 1.5, water is 0.8wt%, ethylene glycol is 23wt%, there are EC and DEG besides water and EG in the product by GC. This shows that EC has not fully hydrolyzed and there are by-products DEG generated. Therefore, the experimental result shows that water ratio should be controlled in 2.0 ~ 2.5.

Effect of Catalyst Dosage

Reaction conditions: reaction temperature is 140℃, water ratio is 2.0, reaction time is about 2h, and the influence of catalyst dosage on the experimental product is discussed by changing its dosage. The experimental results are as Fig.4.

Fig. 4 shows, when the catalyst dosage is less than 2.0%, there are still EC un-reacted in product, and with the increase of catalyst dosage, conversion rate of EC will increase gradually, when the catalyst dosage is 2.0% or higher, conversion rate of EC reaches 100%, but with the increase of catalyst dosage, the selectivity of EG will decline. Therefore, the experimental results show that the catalyst dosage should be controlled at about 2%.

Effect of Reaction Time

Reaction conditions: Reaction temperature is 140℃, water ratio is 2.0, the catalyst dosage is 2%, the influence of reaction time on the experimental product is discussed by changing the length of reaction time. These situations are discussed when the reaction time is respectively 1.0h, 1.5h, 2.0h, 2.5h, 3.0h, the experimental results are as follows.

Fig. 5 shows, when the reaction temperature is 140℃, the reaction time is 2h, both the conversion rate of EC and the selectivity of EG are 100%. When the reaction time is more than 2h, the selectivity of EG will decrease, when the reaction time is 3h, the selectivity of EG is 95%. Therefore, the appropriate reaction time should be controlled for about 2 hours.

Conclusions

(1) When temperature is below 120℃, the conversion rate of EC is lower. When temperature is above 150℃, the decomposition rate of EC is fast, this will lead to the selectivity of EG decrease gradually. So reaction temperature should be controlled between 140℃ and 145℃.

(2) Water ratio can be reduced to about 2.0, close to the theoretical value in this process of the synthesis of ethylene glycol. Compared with the direct hydration process in the current, water ratio decreases significantly, which will greatly reduce the energy consumption needed to evaporate the moisture in the subsequent purification of ethylene glycol.

(3) The study of the effects of the amount of catalyst and reaction time on the product shows that the amount of catalyst should be controlled in 2%, it is appropriate that reaction time should be controlled for about two hours. At this point, EC conversion rate and EG selectivity are both 100%.

(4) According to the study on the influence of reaction temperature, water ratio, amount of catalyst and reaction time on the reaction, the optimum reaction conditions of this process are as following: reaction temperature is between 140℃ and 145℃, water ratio is between 2 and 2.5, mass fraction of catalyst is about 2%, reaction time is about 2h, conversion rate of EC is 100%, selectivity of EG is more than 98%.

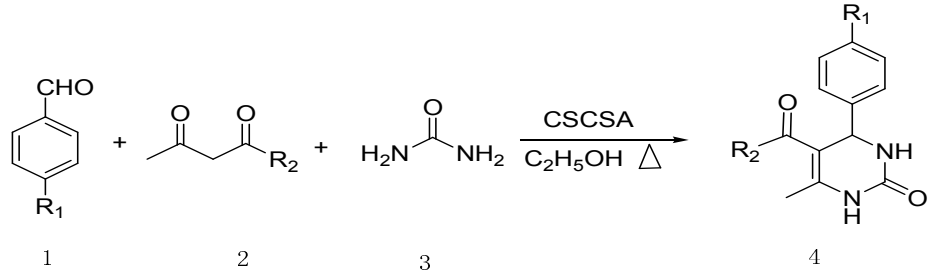
Key words: CSCSA; Biginelli reaction; heterogeneous catalysts; Di-hydropyrimidin

Abstract. 3,4-Dihydropyrimidin-2(1H)-ones derivatives were synthesized in moderate to high yields in one-pot three component reaction from the corresponding aldehydes, 1,3-dicarbonyl compounds and urea, Coconut shell char sulfonic acid (CSCSA) used as a reusable, and efficient catalyst. Compared to the classical acid catalyst, This new protocol for the Biginelli reaction includes the following important features: excellent yields, non-toxic, inexpensive and easily available reagent.

Introduction

3,4-Dihydropyrimidinones (DHPMs) have been reported to possess diverse biological activities, including antiviral, antitumour, antibacterial activities. Functionalized dihydropyrimidinones have been used as potent calcium channel blockers and neuropeptide Y antagonist. Furthermore, several marine alaloids with interesting biological activities containing the dihydropyrimidine-5- carboxylate skeleton were isolated recently[1]. The one-pot, three-component Biginelli condensation provides certainly the most efficient access to DHMP derivatives due to its atom economy feature and the availability in this reaction (Scheme1).The original protocol for the DHPMs reported first by Biginelli in 1893[2], consisted of heating a mixture of the three components in ethanol. Due to the importance of DHPMs, many synthetic methods for the synthesis of this heterocyclic scaffold have been developed[3]. Various homogeneous catalysts[4] and heterogeneous catalysts[5] have been used in Biginelli reaction. In addition, Polymer-supported ionic liquids[6] and microwave irradiation[7] towards Dihydropyrimidinones also have been employed. The discovery and introduction of milder, faster, eco-friendly conditions resulting in high yields whilst using inexpensive reagents are in great demand.



1 2 3 4

Scheme 1. Bilginelli reaction catalyzed by CSCS

Recently, carbon-based solid acids, a novel and inexpensive solid acid with mild acidity, has emerged as a substituted for conventional acidic catalysts in different areas of organic synthesis: esterification, hydrolysis, hydration, etc[13]. This heterogeneous catalyst can be readily recycled and reused through simple filtration, washing and desiccation. Recently we reported the bamboo char sulfonic acid for acid catalyzed reaction of Claisen-Schmidt condensation between benzaldehyde and acetophenone[14]. Here, we report a clean and single-step multi-component reactions of β-ketoesters 1,aldehydes 2 and urea 3 (Scheme 1) in ethanol over CSCSA with high yields.

Experimental

A. Preparation and recycling of CSCSA.CSCSA was prepared according to Xu Qiong's procedure[14]. The catalyst was separated in the first stage of the above work up procedure. The residue was washed with acetone and dried at 100℃ for 5 h to give pure CSCSA for further runs.

B. General procedure for one-pot three-component Biginelli reaction. A solution of ethyl acetoacetate (2 mmol), aldehyde (2 mmol), urea (3 mmol) and CSCSA (20 mol %) in ethanol (5 ml) was heated under reflux for 5-8 h. Upon completion of the reaction, CSCSA then filtered off and the solution poured into crushed ice with stirring. The crude product was filtered, washed with 95% ethanol, dried and recrystallised from hot ethanol to give product 4. Some typical compounds are fully characterised by 1H NMR spectroscopy.

C. Spectral data of typical products. Ethyl\6-methyl-2-oxo-4-phenyl-1,2,3,4-tetrahydro -pyrimidine-5-carboxylate[1H NMR (500 MHz; $CDCl_3$; Me4Si): δ 7.34-7.28(m, 5H, J=4.0 Hz), 5.65 (s, 1H), 5.42 (d, 1H, J=3.0Hz), 4.10-4.09 (m, 2H, J=3.5 Hz), 2.38 (s, 3H), 1.19-1.18 (t, 3H, J=7.5 Hz)]; 5-acetyl-6-methyl-4-phenyl-3,4- dihydropyrimidin-2(1H)-one[1H NMR (500 MHz; $CDCl_3$; Me_4Si): δ 7.34-7.28(m, 5H, J=4.0 Hz), 5.70 (s, 1H), 5.42 (d, 1H, J=3.0Hz), 2.38 (s, 3H), 2.14 (s, 3H)]; Ethyl\4-(4-methoxyphenyl)-6-methyl-2-oxo-1,2,3,4-tetrahydropyrimidine-5-carboxy-late[1H NMR (500 MHz; $CDCl_3$; Me_4Si): δ 7.26-7.24(d, 2H, J=8.5Hz), 6.86-6.84(d, 2H, J=9.0 Hz), 5.76 (s, 1H), 5.37 (d, 1H, J=2.5Hz), 4.11-4.07 (m, 2H, J=4.5 Hz), 3.80 (s, 3H), 2.35 (s, 3H), 1.20-1.18 (t, 3H, J=7.0 Hz)]; 5-acetyl-4-(4-methoxyphenyl)-6-methyl-3,4-dihydropyrimidin-2(1H)-one[1H NMR (500 MHz; $CDCl_3$; Me_4Si): δ 7.24-7.22(d, 2H, J=8.5Hz), 6.88-6.86(d, 2H, J=9.0 Hz), 5.81 (s, 1H), 5.41 (d, 1H, J=2.5Hz), 3.81 (s, 3H), 2.36 (s, 3H), 2.12(s, 3H)]; Ethyl\6-methyl-4-(4-nitrophenyl)-2-oxo-1,2,3,4- tetrahydropyrimidine-5-carboxylate[1H NMR (500 MHz; $CDCl_3$; Me_4Si): δ 8.21-8.20(d, 2H, J=9.0Hz), 7.54-7.53(d, 2H, J=8.5 Hz), 5.76 (s, 1H), 5.54 (d, 1H, J=3.0Hz), 4.14-4.12 (m, 2H, J=6.0 Hz), 2.39 (s, 3H), 1.22-1.20 (t, 3H, J=7.0 Hz)]; Ethyl\4-(4-chlorophenyl)-6-methyl-2-oxo-1,2,3,4- tetrahydropyrimidine-5-carboxylate[1H NMR (500 MHz; $CDCl_3$; Me_4Si): δ 7.30-7.29(d, 2H, J=8.5Hz), 7.25-7.24(d, 2H, J=8.5 Hz), 5.82 (s, 1H), 5.39-5.38 (d, 1H, J=2.5Hz), 4.14-4.12 (m, 2H, J=6.0 Hz), 2.35 (s, 3H), 1.20-1.19 (t, 3H, J=7.0 Hz).

Results and discussion

The results of optimization experiments for the three component Biginelli condensation involving ethylacetoacetate, benzaldehyde and urea with CSCSA as catalysts are presented in Table 1. Entries 1-3 show the effect of various solvents, amounts of catalysts and different common sulfonic groups catalysts on the yield of the reaction. Although CH_3CN and toluene afforded the product in high yields, we chose ethanol for its cheapness and environmental acceptability. The amount of catalysts used equaled acid capacity of CSCSA (entries 3). It is clearly that the yield of DHPMs in the presence of CSCSA is higher than resin. Although sulfamic acid afforded the product in high yields, but high catalytic activity, low toxicity, moisture and air tolerance make CSCSA catalysts attractive.

Encouraged by the remarkable results obtained in the above reaction conditions and in order to show the generality and scope of this new protocol, we further surveyed the scope of benzaldehyde and β-ketoester in the direct Biginelli reactions in the presence of 20 mol % CSCSA as the catalyst and the results were summarized in Table 2.

All the aldehydes studied were smoothly converted to their corresponding 3,4-dihydropyrimidin-2(1H)-ones in excellent yield, which were identified by comparing their spectral data(1H NMR) with those of authentic samples. The use of methyl acetoacetate and acetyl acetone as 1,3-dicarbonyl moieties in place of ethyl acetoacetate also gave similar results, but 1,1,1-Trifluoroacetylacetone was in very low yield.

Finally, the recycling performance of CSCSA was investigated using the three-component Biginelli reaction. The yields of DHPMs were 87.6%, 85.6% and 84.4% respectively, which showed good reusability of this catalyst.

The weight of catalyst increased slightly and no sulfate ion was detected in reaction mixture after each reaction which indicated that reactants or products may deposit in catalyst. Compared with the traditional solvents and catalysts, the easy recycling performance is also an attractive property of the SCSA for the environmental protection and economic reasons.

Finally, the recycling performance of CSCSA was investigated using the three-component Biginelli reaction. The yields of DHPMs were 87.6%, 85.6% and 84.4% respectively, which showed good reusability of this catalyst. The weight of catalyst increased slightly and no sulfate ion was detected in reaction mixture after each reaction which indicated that reactants or products may deposit in catalyst. Compared with the traditional solvents and catalysts, the easy recycling performance is also an attractive property of the SCSA for the environmental protection and economic reasons.

Conclusion

In summary, we herein described an originally and effectively CSCSA catalyzed protocol for the construction of DHPMs via three-component direct Biginelli reaction. This procedure offers several advantages including inexpensive catalyst, excellent yields, clean reaction, easily available reagent, which make it a useful and attractive strategy for the multi-component reactions of combinational chemistry. Current efforts in our research group are attempting to expand the application of CSCSA in other reactions. Therefore, we believe that the work reported here would have potential application in green chemistry.

Study on the Urea Demand Model of SCR Control Technology

Zhilin Liu, Da Wa

Agricultural and Animal Husbandry College of Tibet University, Linzhi, Tibet, China, 860000

linlin0324ok@126.com

Keywords: SCR; Urea; Emission control.

Abstract. In this paper, the NOx emission of original diesel engine and the urea supply model of SCR system under different working conditions of ESC were obtained according the requirement of GB17691-2005[1]. Then the model of urea demand was established, and the comparison was made with the actual urea supply. In addition, the causes of the differences between them were analyzed.

Introduction

In recent years, the rapid development of China's automotive industry has made great contributions to the economic construction of our country, however, its pollution problems have become increasingly prominent, emission control technology of automobile are increasingly widespread attention from all sectors of society [2][3][4]. In order to meet the reality of China's national conditions, many automobile manufacturers and R & D department has find a suitable for China's national conditions of the diesel engine emission control technology---- selective catalytic reduction (SCR) technology, this technology can effectively overcome the influence of sulfur content in diesel oil, thus favored.

SCR technology's reducing agent is urea solution which concentration is 32.5% (mass ratio), spray urea solution into automobile exhaust, it will create NH_3 after hydrolysis at high temperature and under the action of a catalyst, then the NH_3 can react with NOx generated in exhaust, produce water and CO_2, reduce the pollution of the air. The research content of this paper is urea demand model of SCR technology.

Calculation of the theoretical urea solution demand

Assuming you can obtain unit time (usually in hours) parameters of diesel such as exhaust temperature, exhaust back pressure and exhaust mass flow, after conversion to obtain NOx emissions per unit time as A mol.

1mol NOx requires 0.5mol urea. The molecular weight of urea was 60g/mol, concentration of urea aqueous solution is 32.5%, then 1mol urea can be formulated as 60/0.325=184.6 grams' urea solution. Urea aqueous solution's density is 1.09kg/L, so you can obtain 184.6 * 10-3 /1.09 =0.169 L urea aqueous solution when 1mol urea used.

In summary, if eliminate 1 mol NOx, we should use 0.169/2=0.0845L urea aqueous solution. Therefore, the elimination of A mol NOx , 0.0845*A L urea aqueous solution will be required.

Diesel engine NOx emission test

If establish a suited urea demand model for the diesel engine, you should according to the emission characteristics of engine. European steady thirteen conditions test method (ESC) is a standard

method for the determination of diesel engine emission performance, so we used ESC method in our test.

The concentration of NOx can be obtained under different ESC conditions for a diesel engine made in China by ESC method as shown in figure 1.

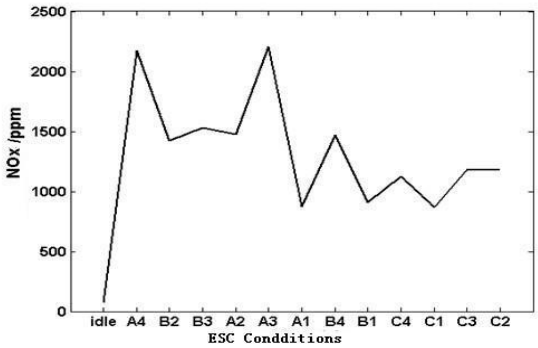

Figure 1 The situation of NOx concentration in original diesel emission experiment

Based on the measured data of each condition test (NOx emission value, gas flow, fuel consumption and exhaust temperature), we can obtain the calculation value of NOx emission is 6.24g/(kw.h) after calculation of standard method. It proves that the tested diesel engine meets national standard Ⅲ because its value less than 6.5g/(kw.h).

Model of theoretical urea aqueous solution demand

The concentration of NOx was obtained by ESC test, then NOx volume flow can get through the calculation of the total exhaust. The amount of air and fuel consumption has been obtained by ESC test. From the mass conservation law we can get exhaust consumption in unit time, then calculate NOx molar flow by exhaust parameters.

Assume that the consumption of air and diesel oil to diesel engine in unit time and a certain condition respectively are Ma and Mo, we can obtain the medium into diesel engine in unit time:

$$M_{in} = M_a + M_o \tag{1}$$

The import and export of medium for the diesel engine should be equal by mass conservation law, that is:

$$M_{in} = M_{out} \tag{2}$$

The diesel engine medium (air and diesel) are discharged in the form of exhaust, that is to say, the amount of air and fuel consumption into diesel are equal to the exhaust volume of the diesel engine per unit time, that is:

$$M_a + M_o = M_{ex} \tag{3}$$

Set in this condition, the exhaust's temperature is T through catalyst, the exhaust back pressure is P (absolute pressure), exhaust molar mass is M=29g/mol, from gas state equation [4], we can get that:

The volume flow of diesel exhaust in unit time (unit: m3/h)

$$\mathrm{Q} = \frac{\mathrm{m} \times \mathrm{R} \times \mathrm{T}}{\mathrm{M} \times \mathrm{P}} \tag{4}$$

Under this condition, the concentration of NOx in the exhaust is A ppm, The pressure and temperature respectively are P_0 and T_0 under standard conditions. Then the volume flow of NOx in unit time can be obtained under standard conditions.

$$Q_S = \frac{T \times P_0}{T_0 \times P} \times Q \times A \tag{5}$$

The molar volume of the gas is V=22.4 L/mol = 0.0224 m3/mol under standard conditions, then the molar flow of NOx in unit time (unit: mol/h) can obtained:

$$Q_M = \frac{Q_S}{V} = \frac{1000 \times Q_N}{22.4} \tag{6}$$

Calculation of theoretical urea aqueous solution demand shows that per mole NOx consumes 0.0845 L urea aqueous solution, therefore, demand for urea solution, namely urea supply flow (unit: L/h)

$$Q_L = 0.0845/Q_M \tag{7}$$

Put the test data measured into formula (1) ~ formula (7), we can obtain theoretical urea solution demand for remove NOx completely under ESC different conditions as shown in table 1.

Table 1 Theoretical urea solution demand

ESC Conditions	Idle	A4	B2	B3	A2	A3	A1	B4	B1	C4	C1	C3	C2
Flow (L/h)	0.04	5.42	3.34	4.60	2.24	4.39	1.17	5.39	1.68	4.83	2.07	4.35	3.50

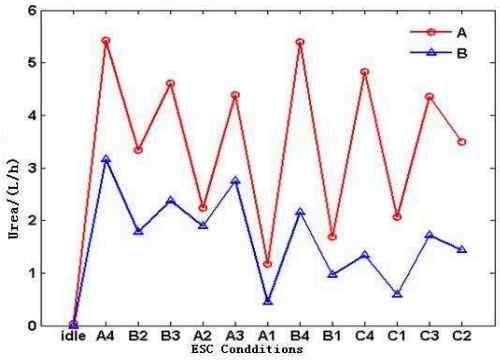
Comparison of theoretical urea solution demand and actual measurement

The urea flow sensor is installed in the nozzle of urea, still do engine test according to ESC , the actual flow of urea aqueous solution can be obtained as shown in table 2.

Table 2 Actual measured urea solution amount

ESC Conditions	Idle	A4	B2	B3	A2	A3	A1	B4	B1	C4	C1	C3	C2
Flow (L/h)	0	3.16	1.79	2.38	1.89	2.76	0.44	2.16	0.96	1.34	0.59	1.72	1.44

The comparison of theoretical and actual aqueous urea solution demand as shown in figure 2.



A- Theoretical demand,B-Actual injection

Figure 2 Theoretical and actual urea solution

Conclusion and discussion

From the comparison and analysis above: the trends of theoretical demand and actual injection for urea are nearly the same, which proved that the model is feasible in some extent.

However, there are some differences between them. Analysis of the causes of these differences, there may be the following three aspects:

1. The control goal of SCR system is based on the national emission standard III to national emission standard IV, so its control strategy is also based on that goal to supply urea, which determines the urea supply and NOx emissions is impossibly 1:1, therefore, differences will produce between theoretical and actual urea solution;

2. The performance of the catalyst is limited. If increase the injection of urea solution (equivalent to the increase NH_3), the conversion efficiency of NOx will be improved definitely. However, leakage of NH_3 will be increased if beyond the processing capacity of the catalyst, also does not meet the emission regulations. Therefore, performance of the catalyst also may be an important reason for these differences.

3. Error measurement and calculation. This error is inevitable, but little effect, can not be considered.

Abstract. The effect of sodium methylacrysulfonate (SMAS) upon the molecular weight, molecular weight distribution and polycarboxylate (PCE)'s dispersion and dispersion-retaining ability were investigated by Gel permeation chromatography (GPC) and test of the fluidity of cement pastes. The results showed that the dosage of SMAS was inversely proportional to the molecular weight of polycarboxylate, and a cubic equation relationship existed between the molecular weight of the polycarboxylate and the reciprocal of SMAS dosage. There was an optimum middle dosage of sodium methylacrysulfonate which could control the molecular weight polycarboxylate, and then affect its dispersion and dispersion maintain performance. The effect of sodium methylacrysulfonate on the monomer conversion rate was also systematically discussed by means of high performance liquid chromatography (HPLC).

Introduction

Polycarboxylate superplasticizer was most favored to industry due to its chemical structure which has the potential to design to meet specific needs in various applications [1-3]. The comb-type structure of PCE consists of several functional groups such as sulfonic acid group, carboxyl group, amino group and PCE long- chain [4-5]. The density and types of the functional groups and the molecular weight and distribution significantly affect the achievement of steric exclusion and electrostatic repulsion, thus definitely influence the dispersion water-reducing properties [6-8].

SMAS is frequently used as an co-monomer in the synthesis of polycarboxylate superplasticizer. It can not only adopt sulfonic acid group with the effect of water reduce, but also have the ability to control the molecular weight and molecular weight distribution due to its chain transfer effect[. Therefore, grasp the impact of such comonomer on the polymerization process of polycarboxylate is of great significance.

In this study, PCE was obtained by the polymerization of TPEG, SMAS and AA, initiated ammonium persulphate. The effect of SMAS dosage on the molecular weight and molecular weight distribution of the synthesized PCE, monomer conversion as well as the PCE's dispersion and dispersion-retaining ability was systematically investigated.

1 Experimental

1.1 Synthesis of PCE

The PCE was synthesized according to previous study by aqueous free radical copolymerization of acrylic acid (AA), SMAS and polyoxyethylene ether (TPEG-2400). Ammonium persulphate (APS) was used as initiator. 100g water and 150g TPEG-2400 were added to a 500ml four-necked flask equipped with a condenser, a nitrogen inlet and a stirring bar afterwards and stirred for 15min to give a homogeneous solution. The solution was gently heated to 60°C and 16.2g AA with 45g water and

amount of SMAS with 55g water was then added to the flask under a fixed feeding rate. After complete the feeding process, the mixture was stirred for several hours under the same temperature. At the end, the pH was adjusted to 7 with 30wt% NaOH and the PCE was acquired.

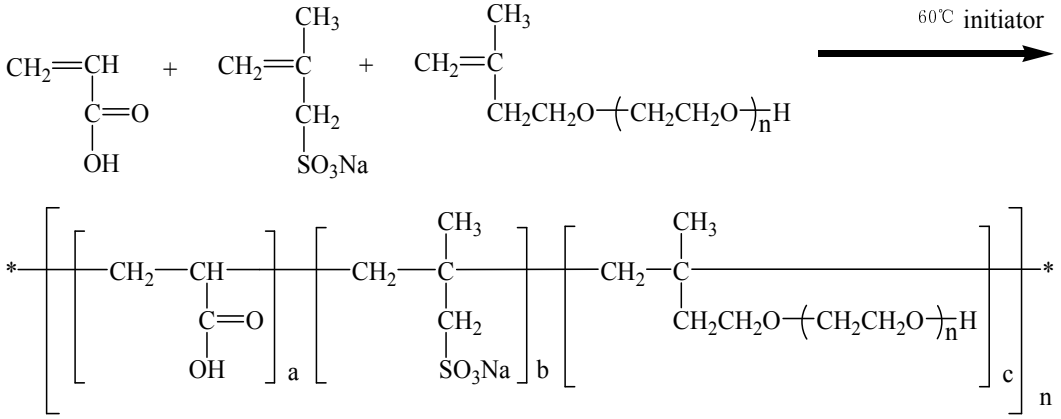

Fig. 1 Reaction equation of the polycarboxylate

1.2 The test of monomer conversion

The monomer conversion of PCE was measured by chromatography system (HPLC, Agilent 1100; Column, SinoChrom ODS-BP (C18) 5μm, 4.6mm × 200mm; detector, λ-35 -type UV spectrum, PE company, USA).

Weigh the test sample superplasticizer 0.10g ~ 0.25g, diluted with the mobile phase to 25mL, filtrated with the 0.45μm filter membrane and chromatographic analysis with external standard method.

1.3 Gel permeation chromatography (GPC)

Molecular weight of PCE was measured by gel permeation chromatography (GPC, Waters 150C, USA), using the solution of methanol and buffer solution (1/2, v/v) as the eluent (Column, PL aquagel, mix/m, 7.8*300 mm, Agilent1100, Agilent Company, USA). The buffer solution was Na2B4O7/KCl aqueous solution (pH = 8). Narrow polyethylene glycol (PEG) was used as calibration standards. The GPC detector included the refractive index.

1.4 Mini slump test

Test of the fluidity of cement pastes added with superplasticizer was under the national standard GB 8077-2000 “methods for testing uniformity of concrete mixture” and the cement used for the test was HUAXIN P·O 42.5, the w/c ratio was 0.29 and the dosage of the PCE was 0.15% (by percent Weight based on solids cement).

2 Experimental results and analysis

2.1 The effect of SMAS dosage on the molecular weight and molecular weight distribution of PCE

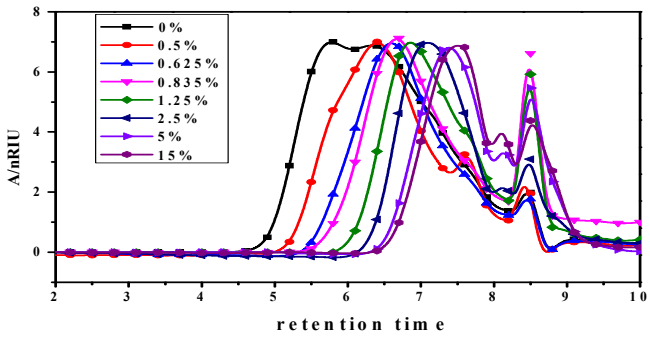

Fig. 2 GPC of PCE with different SMAS dosage

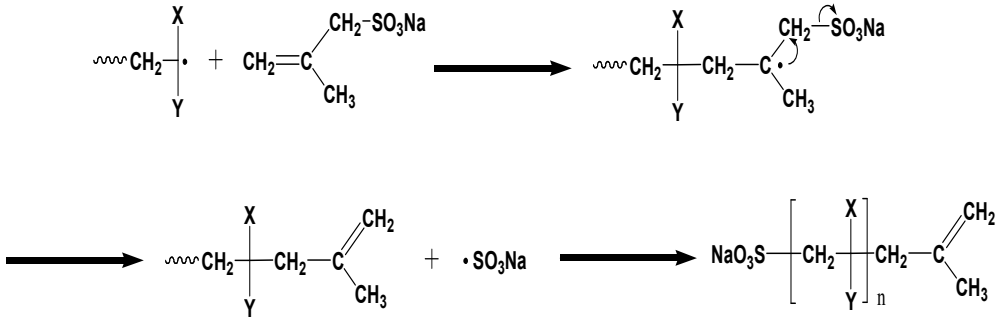

Fig. 3 The chain transfer mechanism of SMAS

The molecular weight and distribution is an important element to the performance of PCE. as can be seen from Fig. 2 and table 1 , the molecular weight of PCE is relatively large (about 230,000) and presents broad molecular weight distribution （DPI = 12.4）and multiple decentralized state in the case of no or small amount of SMAS（0.5% of the total mass of the TPEG-2400 and acrylic acid）, while the molecular weight tend to smaller and the molecular weight distribution of polycaprolactones gained tent to narrow in the case of Further adding of SMAS. This is attributed to the obvious effect of chain transfer of SMAS which belong to the allyl thiosulfate compound. The chain transfer mechanism of SMAS presented in fig. 3

Table 1 The calculated result of fig. 2

SMAS（%）	Mw	Mn	DPI	Mp

2.2 The mathematical fitting model between SMAS dosage and molecular weight

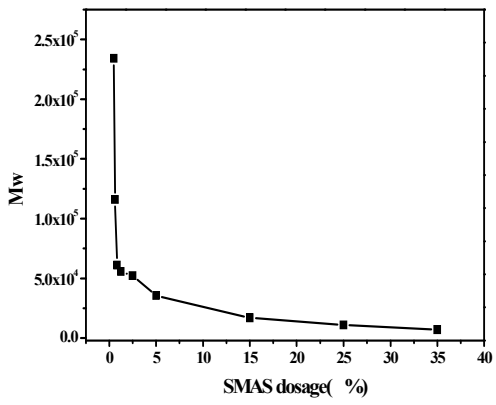

Fig. 4 Relationship between SMAS dosage and Mw

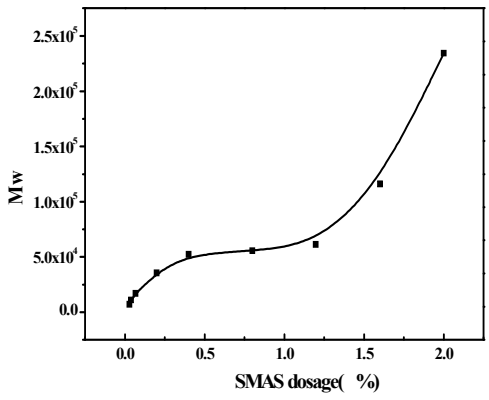

Fig. 5 Relationship between Mw and the reciprocal of SMAS dosage

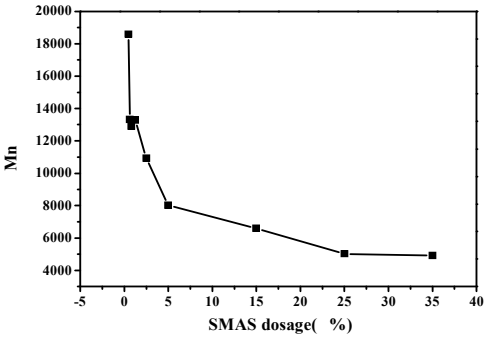

Fig. 6 Relationship between SMAS dosage and Mn

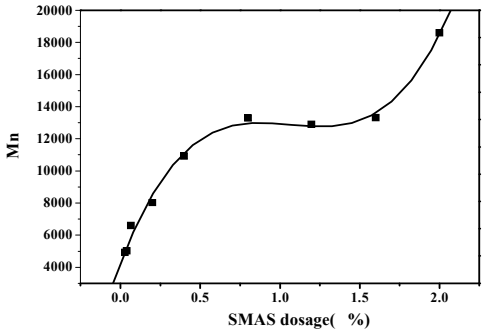

Fig. 7 Relationship between Mn and the reciprocal of SMAS dosage

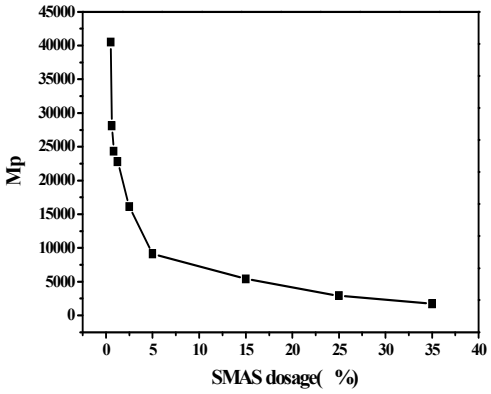

Fig. 8 Relationship between SMAS dosage and Mp

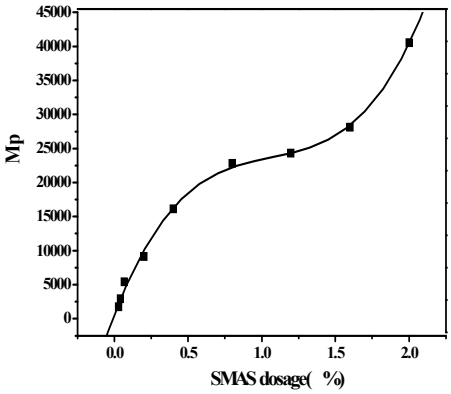

Fig. 9 Relationship between the reciprocal of SMAS dosage and Mp

Fig. 4, Fig. 6 and Fig. 8 was made according to the SMAS dosage and molecular weight (Mw, Mn and Mp) from the date of table 1. Fig. 5, Fig. 7 and Fig. 9 was gained by plotting and polynomial fitting according to the reciprocal of SMAS dosage and molecular weight (Mw, Mn and Mp). The mathematical fitting formula was listed in table 2

It can be seen from the Fig. 4, Fig. 6 and Fig. 8, the molecular weight is inversely proportional to the amount of the SMAS dosage. Fig. 2.5, Fig. 7, Fig. 9 and table 2 display a cubic equation relationship between the molecular weight of the polycarboxylate and the reciprocal of SMAS dosage.

Table 2 The mathematical fitting model

	Polynomial	The correlation coefficient（R^2）
Mw	Y= 100469X3 – 240107X2 + 194124X + 4094.4	0.9988
Mn	Y= 7893.4X3 - 25252X2 + 26048X + 4247.2	0.9936
Mp	Y = 15234X3 - 48576X2 + 56074X + 668.3	0.9977

Wherein Y represents molecular weight of polycarboxylate superplasticizer; X represents the reciprocal of SMAS dosage

2.2 The effect of SMAS dosage on the PCE's dispersion and dispersion-retaining ability.

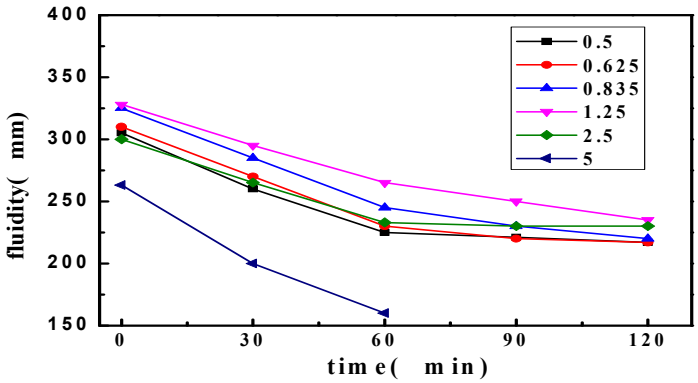

Fig. 10 Fluidity of the cement paste of PCE with different SMAS dosage

As can be showed from Fig. 10, the fluidity of the cement paste increase as the SMAS dosage increase and then decrease when the SMAS dosage continue to increase. The dates of the fluidity-loss within different time also show the same tendency. This is mainly due to that SMAS can control the molecular weight of polycarboxylate as discussion of 2.1, and then affect its dispersion and dispersion maintain performance. Therefore，there was a optimum middle dosage of SMAS. It can be ascribed that under this optimum middle dosage of SMAS, the molecular weight can reach a relatively optimum value, which can benefit the PCE's electrostatic repulsion of electric charges and the steric hindrance[9].

2.2 Effect of SMAS dosage on the monomer conversion

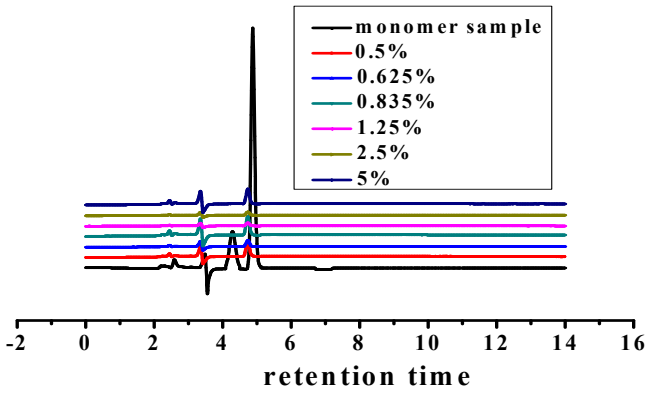

Fig. 11 The HPLC of monomer sample and PCE with different SMAS dosage

Table 3 The calculated results of Fig. 11

SMAS dosage	0.5%	0.625%	0.835%	1.25%	2.5%	5%
monomer conversion	99.11%	98.80%	99.55%	99.49%	98.52%	99.45%

According to Fig. 11, the monomer sample of SMAS and AA response to the peak at 4.3 and 4.9 minutes, respectively [10]. While there are no response peaks at 4.3 min and 4.9 min for the PCE sample of different SMAS dosage, which means SMAS and AA almost completely react. Table 3 also shows that SMAS does not affect the rate of monomer conversion.

3 Conclusion

This work confirms that SMAS has obvious effect of chain transfer. The molecular weight of PCE is inversely proportional to the amount of SMAS dosage. More precisely speaking, molecular weight of PCE and the reciprocal of SMAS dosage abide by the cubic polynomial fitting mathematical model. SMAS dosage decide the molecular weight of PCE and then affect its dispersion and dispersion maintain performance. A optimum middle dosage of SMAS exist which make the molecular weight can reach a relatively optimum value and benefit the PCE's dispersion and dispersion-retaining ability. The results of HPLC prove that SMAS does not cause the slightest impact on the rate of monomer conversion.

Keywords: Superplasticizers, Water-reducing Performance, pH Value, Room Temperature

Abstract. In order to study the effect of the pH value of reaction system on the properties of polycarboxylate-based superplasticizers (PC) and on the cement workability, the PC are synthesized in different pH environments from 3 to 11 at room temperature. The results show the water-reducing performance of PC can be tuned by controlling the pH value of reaction system at room temperature, which affects not only the efficiency and rate of redox initiator systems but also the reactivity of active monomers.

1. Introduction

Superplasticizers, such as sulfonated melamine formaldehyde (SMF) condensate, sulfonated naphthalene formaldehyde (SNF) condensate and acrylic polymer (AP), are incorporated in concrete mainly to modify its workability in the fresh state, and to yield high concrete strength and durability at low water/cement ratios [1][2]. Nowadays, superplasticizers are absolutely necessary for the production of high performance concrete, and are known as the fifth component of concrete, besides cement, sand, gravel and water [3]. Recently, polycarboxylate-based superplasticizers have been developed and commonly used in the construction industry, due to their outstanding water reducing ratio, high workability retention at small dosages, and excellent compatibility[4][5].

The effects of the superplasticizers on the properties of cementitious system depend on various designs of molecular structures. Apart from the functional groups and chemical configuration, the molecular weight and its distribution of superplasticizers have a significant impact on the properties of concrete [6]. Up to now, most of the research focuses on the effect of initiator concentration, reaction temperature and time, the feeding methods, and monomer proportion on the performance of water-reducing agent[7][8]. However, very few researches concern about the change of the pH value during the polymerization reaction. Since the pH value of reaction system affect not only the efficiency and rate of redox initiator systems but also the reactivity of active monomers, the chain structure and molecular weight distribution of the superplasticizers can undergone a corresponding change [9].

In this paper, the pH value of reaction system has successfully been controlled by the addition of sodium hydroxide solution and acrylic acid monomer. The addition of sodium hydroxide solution causes the increase of the pH value by neutral reaction with acrylic acid, whereas the addition of acrylic acid decreases the pH value by the increasing concentration of hydrogen ions. The relationship between the pH value of reaction system and water-reducing performance of PC has been investigated by evaluating the workability of cement paste.

2. Experimental

2.1 Raw materials

The cement used is commercially available normal Portland cement from Huaxin cement factory in china. The specific characteristics of raw materials are shown in *Table 1*.

The Polyether Macromer (F108) is obtained from Liaoning Kelong Fine Chemical Co., Ltd. Acrylic acid (AA), sodium methallyl sulfonate (SMS), hydrogen peroxide (H_2O_2), ascorbic acid (Vc) and sodium hydroxide (NaOH) are purchased from Sinopharm Chemical Reagent Co., Ltd. All the

copolymerization reactions are carried out in an aqueous medium at room temperature for 2 hours using hydrogen peroxide as an initiator and ascorbic acid as an activator, respectively, under a nitrogen gas atmosphere. The polymer solutions have a solids content of 40 wt%, determined by oven drying method. The pH value of reaction system is adjusted by the addition of sodium hydroxide solution and acrylic acid monomer. PC3 stands for the PC synthesized at the pH value of 3 and the PC9 stands for the PC synthesized at the pH value of 9.

Table 1 Characteristics and Chemical compositions of raw materials

Materials	Chemical compositions (%)							Specific surface (m^2/kg)
	SiO_2	Al_2O_3	Fe_2O_3	CaO	MgO	SO_3	Loss	
Cement	22.1	6.08	3.04	58.6	3.32	2.08	2.38	346

2.2 Evaluation

The cement pastes are prepared at a water to cement ratio (w/c) of 0.29 with the PC dosage of 0.15% against the mass of cement using an epicyclical mixer. The spread diameter of the cement cake is measured, which is used for measuring its fluidity. The cement paste is monitored over time to determine paste loss, and measurements are made every 30 min up to 120 min.

Molecular weights (Mw, Mn) of synthesized PCs are determined by gel permeation chromatography (GPC) using 0.1mol/L buffer solution of phosphoric acid as a mobile phase at a flow rate of 1.0 mL/min.

The IR spectrum analysis are determined with AVATAR-370 infrared spectroscopy (Thermo Nicolet Company, US) working at a resolution of 4 cm^{-1} and an accumulation of 32 scans. The spectra are recorded from KBr pellets, weighing 300 mg of KBr and 1 mg of admixture.

3. Results and discussion

3.1 Characterization of synthesized PCs by the FT-IR spectrum

The infrared spectrum for the PCs at different pH value of reaction system are given in *Fig.1*, as the FTIR spectrum has been proved to be a useful tool to effectively character the functional group of polymer [10]. It can be found that the absorption band in 3433 cm^{-1} corresponds to the stretching vibration of hydroxyl groups. The band at 2877, 1458, 1352 cm^{-1} arises from the C–H stretching and bending vibration in the methylene group. The absorption bands appear at 1107 cm^{-1} assigned to stretching vibrations of the characteristic absorption peaks of ether groups in the polyether side chain. Absorption bands at 1643 and 951 cm^{-1} could be assigned to the stretching vibrations of carbonyl groups.

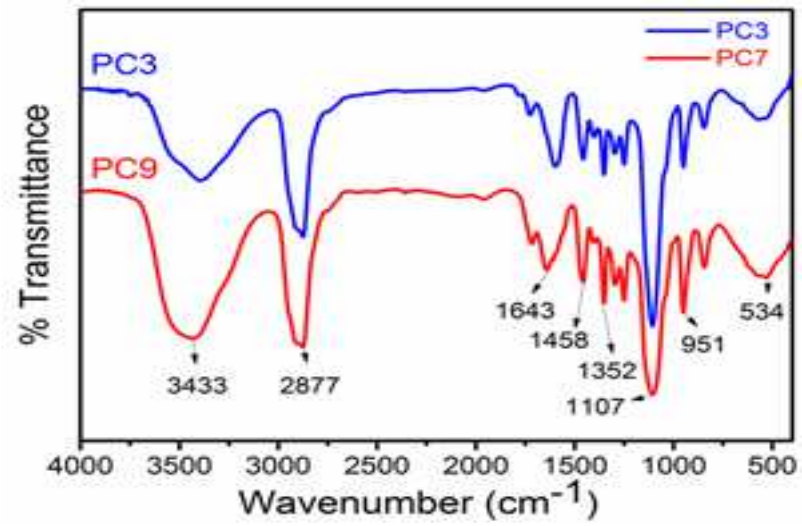

Fig.1 The infrared spectrum for the PCs at different pH value of reaction system

According to the result of the FT-IR spectrum, it is obviously proved the functional groups have been successfully copolymerized to the molecular structure of PCs. However, the PCs synthesized at different pH value of reaction system is not shown much difference in the whole spectrum, except for little varied intensity of peaks in some groups, which can easily be deduced those PCs have similar functional groups.

3.2 The molar masses and polydispersities of PCs synthesized at different pH

As the pH value of reaction system affect not only the efficiency and rate of redox initiator systems but also the reactivity of active monomers, the molecular weight and its distribution of the PCs will make a big difference. The molar masses and polydispersities of PCs synthesized at different pH are shown in *Fig.2* and the statistical data are displayed in *Table 2*. The polydispersity index (PDI) is obtained by dividing the weight average molecular weight (Mw) by the number average molecular weight (Mn). It describes the uniformity of a polymer with respect to molecular mass distribution. It can also be seen that polymer molecules with higher molecular weight elute earlier from the chromatography column.

Since the synthesis conditions remained the same for all polymerizations, apart from the pH value of reaction system being varied, the mean polymer weights decrease accordingly from PC3 to PC9. It appears to be obvious that PC3 has a much lower polydispersity than PC9. The initiator and monomers possess higher reaction activity under acidic conditions, which are rapid and dramatic in initiating the polymerization, resulting smaller molecular weight and wider distribution than alkaline environment. The both of the PCs were shown only small amounts of unreacted monomers or by-products formed can be observed at higher elution times.

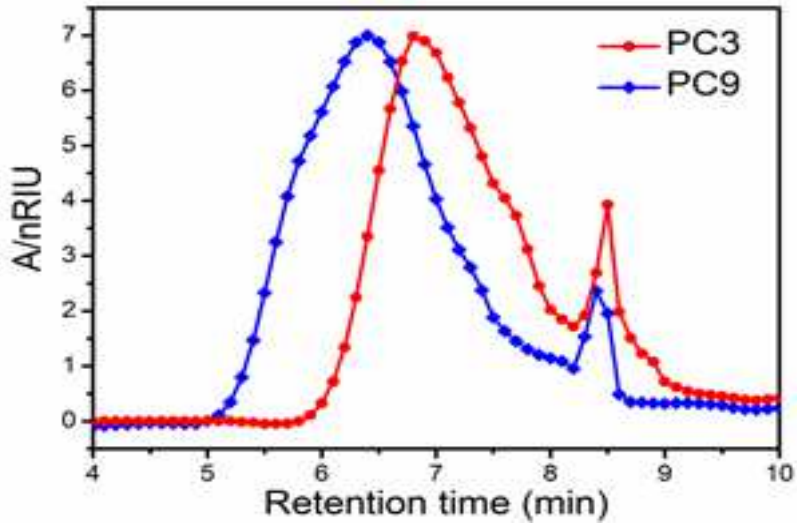

Fig.2 GPC spectrum of different PCs synthesized at the pH value of 3 and 9.

Table 2 Molar masses and polydispersities of PCs synthesized at different pH

Sample	Mw	Mn	DPI
PC3	17020.6	8017.8	2.1
PC9	52219.6	13287.9	3.9

3.3 Effect of different PCs on dispersion of cement pastes

The effect of PCs synthesized at the pH value of reaction system on the fluidity of cement paste is shown in *Fig.3* as a function of pH value and time elapsed. It is can be seen the initial fluidity of the cement pastes is decreased with the increasing pH value of reaction system, which is largely reduced from 330 mm to 140 mm. However, the fluidity retention capacity of the cement pastes is shown an obviously contradictory trend.

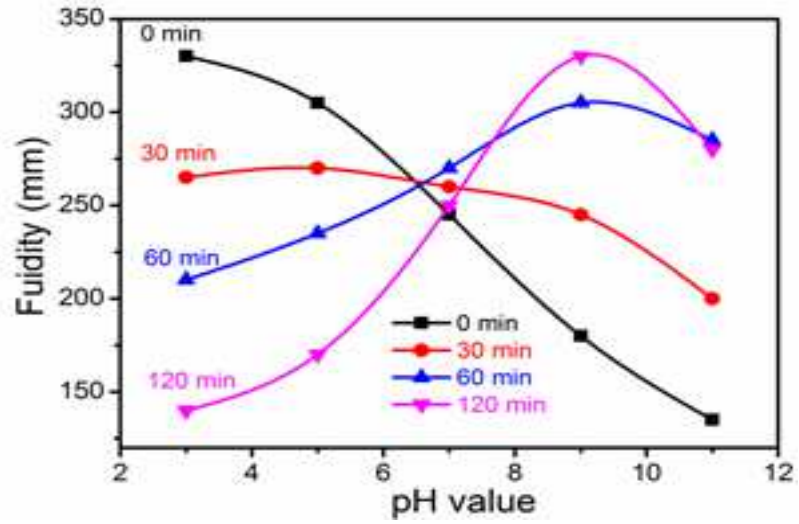

Fig.3 Effect of the pH value of reaction system and time elapsed on fluidity of cement pastes.

Fluidity loss of cement pastes could result from the drop of dispersive capacity caused by the vanishing of PCs with time elapsed. The more amount of adsorption of PCs on the surface of cement particles is, the better fluidity of cement paste is and the less amount of the rest of PCs in solutions at the same time is, which will decrease the ability of fluidity retention. Since the adsorption rate of PCs with higher molecular weight is slower than the lower ones, the corresponding cement pastes possess smaller initial fluidity but higher the fluidity retention capacity. As the molecular weight increasing, the initial fluidity of the cement pastes become smaller and the fluidity retention capacity become larger, it is likely that the adsorption of PCs with wider molecular weight distribution are more durable.

4. Conclusions

In summary, not only the effect of the pH value of reaction system on the molecular weight and its distribution of PCs, but also the corresponding dispersion and workability behavior of cement paste are investigated systematically in this paper. The results show that the PCs synthesized at the higher pH value of reaction system possess higher molecular weight and wider distribution, resulting in smaller initial fluidity but higher fluidity retention capacity. Since tuning the water-reducing performance of PCs by controlling of the pH value of reaction system at room temperature is simple and effective in this redox initiator system, this method has tremendous potential to be applied in laboratorial and industrial synthesis.

KeyWords: block copolymer; Pluronic F87; PLA; paclitaxel; in vitro release

Abstract: Pluronic F87/Poly(lactic acid)block copolymer (PLA-F87-PLA) was synthesized by bulk polymerization. Paclitaxel-loaded PLA-F87-PLA nanoparcticles were prepared by a dialysis method. The loading efficiency was determined by UV. The results showed that the loading efficiency of paclitaxel for PLA-F87-PLA nanoparticles was 69%. In vitro release behavior of paclitaxel-loaded PLA-F87-PLA nanoparticles was studied by HPLC. In vitro release behavior showed an initial rapid release followed by a slow release. The biocompatibility of nanoparticles was measured by MTT. The viability of paclitaxel-loaded PLA-F87-PLA nanoparticles was less than that of free paclitaxel. The results indicated that PLA-F87-PLA copolymer has good biocompatibility.

Introduction

Biocompatible amphiphilic copolymers are able to self-assemble into nanoparticles with different morphologies in aqueous solution. Drug can be entrapped within the nanoparticles. Hydrophilic segments in surface can protect the drug would not be destroyed. Therefore, the method has been widely used to application of drug delivery stystems[1-3].

Paclitaxel is a natural anti-cancer drug extract from Taxus plant. It has a good effection on breast cancer, ovarian cancer, liver cancer and other cancers. Because the water solubility of paclitaxel is extremely low, the administration in clinical adopts injection mode. Paclitaxel was dissolved in the mixture of polyoxyethylene castor oil and ethanol solution and administration. However, polyoxyethylene castor oil is easy to cause serious adverse effects so that clinical application is limited. To avoid the negative effects, a variety of carriers were used to loaded paclitaxel, which is widely applied in current research, such as liposome[4], chitosan[5], Polymeric micelles[6] and so on.

Poly(ethylene oxide)-poly(propylene oxide)-poly(ethylene oxide) (PEO-PPO-PEO) triblock copolymer is an important amphiphilic molecules, commercially available as Pluronics. The U.S. Food and Drug Administration (FDA) has approved its application in food additives and pharmaceutical ingredients [7-9]. PLA is a well-known biodegradable and biocompatible polyester. Its degradation products are carbon dioxide and water, which can be excreted through the kidneys in human body.

Thus, in this study, PLA-F87-PLA block copolymer was synthesized. The block copolymer can be used as carrier material. Paclitaxel-loaded PLA-F87-PLA nanoparcticles were prepared by a dialysis method. The morphology of the nanoparticles and their in vitro release behaviors were studied.

Materials and Methods

Materials

Pluronic F87 ($\overline{Mn}$ 7700, 70wt% PEO) was kindly supplied by BASF Corporation. L-lactide and stannous octoate [$Sn(Oct)_2$] was purchased from Sigma-Aldrich. Paclitaxel was kindly supplied by Fujian Nanfang Biotechnoloty. MTT was purchased from Solarbio and used as received.

Dulbecco's Modified Eagle's Medium(DMEM) was purchased from Gibco and used as received. All other chemicals were of reagent grade. Human ovarian cancer cells OVCAR-3 was purchased from CICAMS.

Synthesis of PLA-F87-PLA block copolymers

PLA hydrophobic chains were attached to both ends of Pluronic F87 using $Sn(Oct)_2$ as the catalyst to obtain amphiphilic block copolymers PLA–F87–PLA. The synthesis procedure of PLA–F87–PLA is described as follows. A round bottom flask with a stopcock was heated to remove the moisture under reduced pressure. After being cooled to room temperature, argon was introduced into the flask. After this, LA and F87 were added and heated to form a well-mixed molted phase. $Sn(Oct)_2$ was added to the flask under argon environment when the mixture was cooled. The vacuum-purge cycle was repeated to remove oxygen in the flask, and the mixture was heated to 160 °C. After being stirred for 15 h, the reaction product was cooled to room temperature. The product was dissolved in methylene chloride and precipitated once in 10-fold volume of cold methanol and once in 10-fold volume of cold diethyl ether. The white product was filtered and dried overnight under vacuum.

Preparation of PLA-F87-PLA nanoparticles

PLA-F87-PLA block copolymer was dissolved in THF and then the polymer solution was added drop wise to ultra pure water. The polymer aggregates solution was dialyzed against ultra pure water for 5 h using a cellulose membrane tubing (molecular weight cut-off 12,000 – 14,000 Da) to remove THF from the solution. The water was exchanged at intervals of 1 h and the final concentration of PLA-F87-PLA aggregates is about 0.1 wt %.

Preparation of paclitaxel-loaded PLA-F87-PLA nanoparticles

PLA-F87-PLA block copolymer and hydrophobic drug paclitaxel were dissolved in THF and then the solution was slowly added drop wise to the ultra pure water under gentle stirring. The drug-loaded polymer aggregates in water were against distilled water using dialysis membrane to remove THF and excess drug molecules outside the particles. Finally, the paclitaxel-loaded PLA-F87-PLA nanoparticles was prepared.

Transmission electron microscope

TEM was performed on a HITACHI H-600 electron microscope at an acceleration voltage of 75 kV. The copper grid (300 meshes) with a carbon film was used. A drop of PLA-F87-PLA nanoparticles solution dripping on the sealing membrane to form a droplets. The copper grid was immersed in the droplets for 3 min and then removed the solution from the edge using filter paper. A drop of sodium phosphotungstate (2 wt %) was placed on the copper grid for 2 min. The copper grid was then dried overnight at room temperature before measurement.

Paclitaxel Loading Study

In order to determine the loading efficiency and loading capacity, a small amount of paclitaxel-loaded PLA-F87-PLA nanoparticles solution was lyophilized and then dissolved with THF. Using a Lambda 35 UV-Vis spectrophotomete determined paclitaxel content. The detection wavelength was 252 nm (paclitaxel characteristic absorption peak at 252nm wavelength).Using THF as the blank control. The loading efficiency and loading capacity of paclitaxel into PLA-F87-PLA nanoparticles were calculated as follows:

$$\text{loading efficiency} = \frac{\text{paclitaxel in nanoparticles (mg)}}{\textit{Total}\ \text{paclitaxel in fomulation (mg)}} \quad (1)$$

$$\textit{loading}\ \text{capacity} = \frac{\text{paclitaexl in nanoparticles (mg)}}{\text{nanoparticles recovered (mg)}} \quad (2)$$

In vitro release study

Paclitaxel-loaded PLA-F87–PLA nanoparticles solution was added into the dialysis membrane and then placed in 0.01 M phosphate-buffered saline (PBS, pH 7.4) aqueous solution. The whole solution was then placed in a shaking water bath at 37◦C for the drug-release study. At predetermined time intervals, taking 5 ml released paclitaxel solution outside the dialysis membrane while adding 5 ml fresh PBS replacement to maintain the volume of the release sample. The

released paclitaxel solution was measured by HPLC to determine the concentration of paclitaxel. An AGilent HPLC Series 1100 equipped with a UV-Vis detector, connected with a zorbax Eclipse XDB-C18 column. Chromatographic conditions as follows: Acetonitrile/PBS aqueous solution (50:50 v/v) as the mobile phase. Flow rate was1.0ml/min. Detection wavelength was 227 nm. Column temperature was 30 ◦C.

In vitro cytotoxicity study

OVCAR-3 cells were cultured in DEME supplemented with 2.0mM glutamine, 10% fetal bovine serum, 100ug/ml streptomycin sulfate and 100U/ml penicillin at 37 ^{0}C in humidified 5% CO_2. OVCAR-3 cells were seeded on 96-well culture plates at a cell density of 2.5×10^5 L^{-1} and cultured for 8h. Following this, the medium was removed and cells were incubated with PLA-F87-PLA nanoparticles solution and paclitaxel-loaded PLA-F87-PLA nanoparticles at paclitaxel concentrations between 0.1 and 10mg/l for 24h. Following this, 20ul MTT solution (5g/l) was added to each well and incubated for 4h under normal growing conditions. Then all media was removed and 150ul dimethylsulfoxide(DMSO) was added. After shaking the plate for 10 min, the absorbance was determined at 492nm using a microplate reader(Thermo Labsystems MK3). The cell viability was calculated as follows:

$$\text{Viability}(\%)=(\frac{A_{test}}{A_{control}})\times100\%$$

Where A_{test} and $A_{control}$ are the absorbance of surviving cells treated with nanoparticles and untreated cells, respectively.

Results and Discussion

synthesis and characterization of PLA–F87–PLA block copolymer

The amphiphilic block copolymers PLA–F87–PLA were synthesized by ring opening polymerization of the monomer L-lactide using F87 as the initiator and $Sn(Oct)_2$ as the catalyst via co-ordination polymerization mechanism. The polymer structure and molecular weight were characterized by ^{1}HNMR. Figure 1 shows a ^{1}HNMR spectrum of a typical PLA-F87-PLA in $CDCl_3$. The small peak at δ of 4.30 ppm belongs to methylene protons of the PLA-CO-OC$\underline{H_2}$-CH_2-O-PEO segment. It was indicated that the PLA-F87-PLA block copolymer was synthesized successfully. According to the ^{1}HNMR spectrum, the number-average molecular weight ($\overline{M}$n) of the PLA-F87-PLA copolymer was 21400.

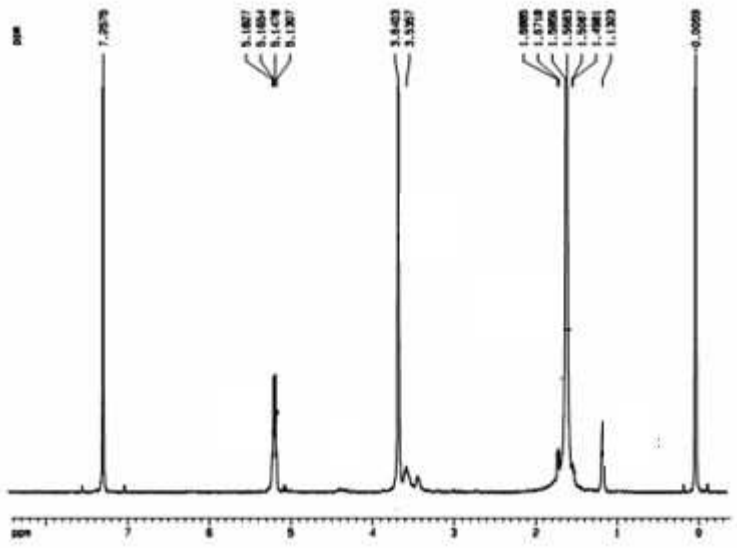

Figure 1 ^{1}H NMR spectrum of PLA-F87-PLA

Characterization of nanoparticles

The particles size and size distribution of PLA-F87-PLA nonoparticles and paclitaxel-loaded PLA-F87-PLA nonoparticles were determined by DLS method using PSS Particle Sizing Systems. The figure 2 shows the intensity-weight Gaussian distribution of PLA-F87-PLA nonoparticles. It was

observed that the PLA-F87-PLA nonoparticles showed a single, narrow distribution. The particle size of PLA-F87-PLA nanoparticles was 175nm.

The morphology of PLA-F87-PLA nanoparticles was examined by TEM. The nanoparticles was negatively stained by sodium phosphotungstate. Figure 3 shows the TEM pictures of PLA-F87-PLA nanoparticles. It was shown that PLA-F87-PLA nanoparticles is spherical core-shell micelles

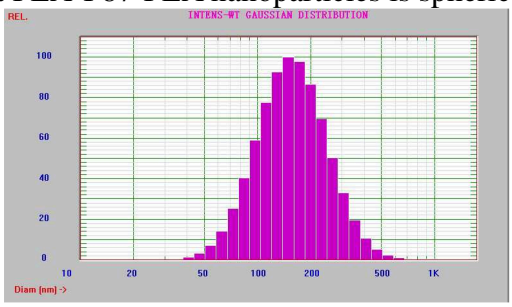

Figure 2 The intensity-weight Gaussian distribution for PLA-F87-PLA nanoparticles

Figure 3 Transmission electron microscopy images of PLA-F87-PLA nanoparticles

Paclitaxel-release study

Paclitaxel–release study from PLA-F87-PLA nanoparticles was performed in PBS solution at 37℃. The loading efficiency and loading capacity of paclitaxel for PLA-F87-PLA was 69% and 9.3%, respectively. Figure 4 shows the drug-release profiles of paclitaxel-loaded PLA-F87-PLA nanoparticles. This study suggested that paclitaxel-loaded PLA-F87-PLA nanoparticles presented an initial rapid release of the front 20h, and then shows a slow release within a time of up to about 4d, and only about 20% of paclitaxel loaded in PLA-F87-PLA was released. Part of the hydrophobic paclitaxel could forms aggregates due to the hydrophobic interaction within the PLA core of PLA-F87-PLA nanoparticles, thus resulting in their non-diffusible property.

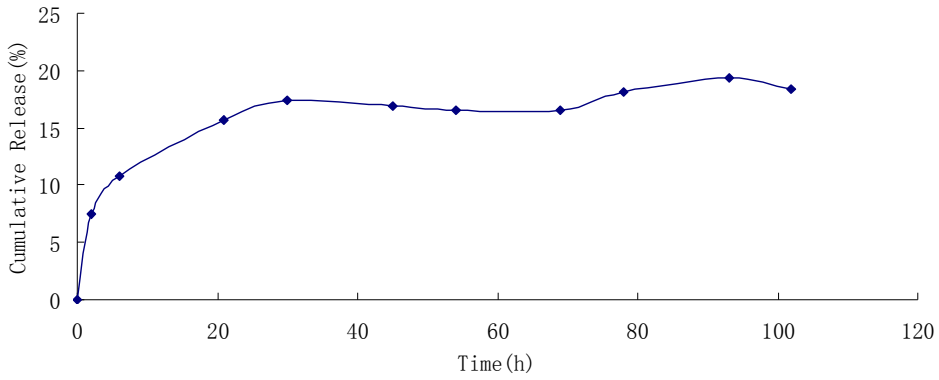

Figure 4 The release behaviors of pacliaxel-loaded PlA-F87-PLA nanopariticles

Cell cytotoxicity

The cytotoxicity of paclitaxel-loaded PLA-F87-PLA nanoparticles was evaluated using MTT assay. Figure 5 shows the viability of OVCAR-3 cells treated with paclitaxel-loaded PLA-F87-PLA nanoparticles and free paclitaxel. The data were analyzed by t test. The P values were 0.002, 0.04 and 0.04, respectively. They were less than 0.05. Results show that there is statistically significant

correlation between paclitaxel-loaded PLA-F87-PLA nanoparticles and free paclitaxel. Besides, it can be seen from figure 5 that the viability of paclitaxel-loaded PLA-F87-PLA nanoparticles was less than free paclitaxel and the viability of paclitaxel-loaded nanoparticles decrease with the increasing paclitaxel concentrations. This study suggests that the ability to kill cancer cells for paclitaxel-loaed PLA-F87-PLA nanoparticles is stronger than that for free paclitaxle.

In addition, in order to validate the cytotoxicity of blank PLA-F87-PLA nanoparticles, PLA-F87-PLA nanoparticles (115mg/L) was used to treated OVCAR-3 cells. The viability of OVCAR-3 was 76%. PLA homopolymer and Pluronic F87 are well-known biocompatible polymers. The earlier results indicate that PLA-F87-PLA block copolymer also has good biocompatibility..

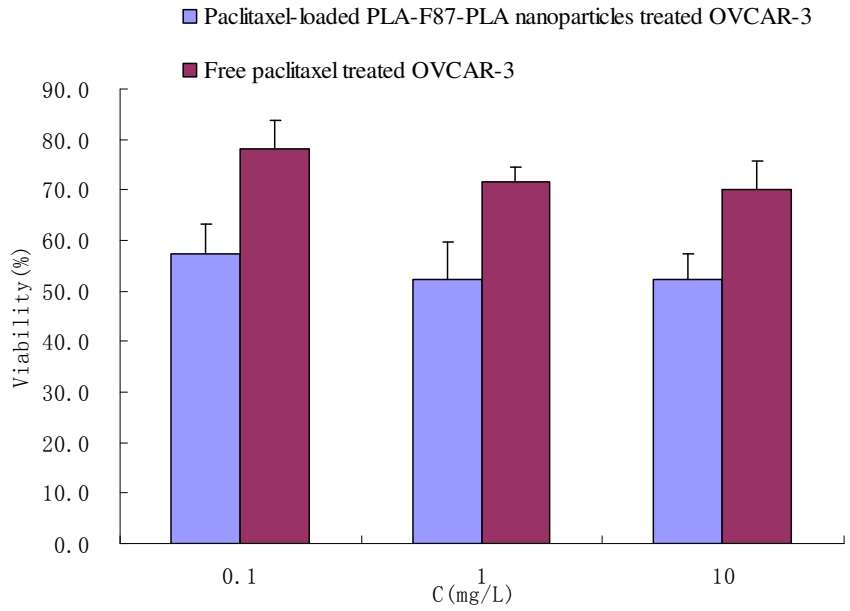

Figure 5 Cytotoxicity of OVCAR-3 cells treated with paclitaxel-loaded PLA-F87-PLA nanoparticles and free paclitaxel

Conclusions

In this study, PLA-F87-PLA copolymer was synthesized. The self-assembling behaviors of PLA-F87-PLA in aqueous solutions were examined. The release of paclitaxel loaded in PLA-F87-PLA nanoparticles shows an initial burst release in the front 20h, and followed by a slow release, only about 20% paclitaxel was released. PLA-F87-PLA copolymer was found to have good biocompatibility by MTT assay using human ovarian cancer cells OVCAR-3. The study of PLA-F87-PLA copolymer on the application of drug delivery systems is on progress.

Keywords: Reclaimed Water Reuse; High-Efficiency Reverse Osmosis; Power Plant

Abstract. Because of the poor quality of the operational water (urban reclaimed water) of one power plant in Hebei, China, a high-efficiency reverse osmosis (HERO) system with foreign patents is utilized for advanced treatment of the reclaimed water. The influence of the main factors (including the alkalinity and the suspended solid content of the feed water, the flux, and the pH of the concentrated water) on the performance of the HERO system were studied. The high alkalinity (high concentration of carbonate) of the feed water resulted in HERO scaling, and the low alkalinity caused the penetration of hardness through the weak acid ion exchangers and, therefore, also caused HERO scaling. The high suspended solid content of the feed water caused rapid decrease in the product flux of HERO. The low concentrated water flux also decreased the product flux. As the pH of the concentrated water became higher, the stability of the HERO operation increased. Based on the pH endurance of the membranes and the characteristic of the high-pH operation of the HERO system, the water production was basically stable when the pH of the concentrated water lay between 10.5 and 10.8. Affected by the ammonia in the reclaimed water, the pH of the product water was higher than that of the feed water. The pH of the feed water was higher than that of the concentrated water. When the pH of the concentrated water was above 10.8, the pH values were close to one another. The results of the chemical cleaning experiments indicated that hardness, phosphorus, ammonia, silicon dioxide, and iron ions were the main influencing chemical factors of HERO, in which the former three formed a sediment of magnesium ammonium phosphate, and the latter two formed an iron silicate sediment.

One thermal power plant in Hebei, China consists of 2×300 MW sub-critical heat-supply units, and reclaimed water from a sewage treatment plant is utilized as the source of the thermal network replenishment and chemical make-up water. Most wastewater that enters this sewage treatment plant comes from the industrial processes and the quality of the wastewater changes greatly with the change in the seasons. Taking into consideration that water contains abundant organic compounds, surfactant, and ammonia nitrogen, the combined techniques of lime treatment and high-efficiency reverse osmosis (HERO) are utilized to treat the reclaimed water. The system has been operating for nearly three years. The HERO technology performance shows that it has its own characteristics that are much different from the conventional reverse osmosis.

1 Process and characteristics of HERO

The HERO process in the advanced treatment of the reclaimed water is shown as follows: product water of lime treatment→ high-efficiency filters→ sodium cation exchangers→ weak acid

cation exchangers→ acid dosing→ decarbonators→ sodium hydroxide dosing→ HERO→ product water sent to the thermal network replenishment and chemical make-up water systems.

Throughout the entire process, the suspended solid content of the product water from lime treatment is reduced by the high-efficiency filters. Then, hardness is completely removed by the sodium cation exchangers and weak acid cation exchangers. After acid dosing, carbon dioxide is removed by the decarbonators. The pH is further adjusted to the range from 10.0 to 11.0 by sodium hydroxide dosing, and the water enters the reverse osmosis system. Finally, softened water with high pH is produced and sent to the users.

HERO is a technology with foreign patents, and the system in this power plant was the first system in China that applies HERO for reclaimed water treatment. The main feature of HERO is that the operational recovery rate could increase to 90% or higher. The system is less prone to scaling and fouling, and the membrane flux is much higher than that of the conventional reverse osmosis, which means that HERO produces much higher amount of product water than the conventional reverse osmosis, using the same amount of membrane modules. In addition, the scale inhibitor dosing is not required in the HERO system operation. Only the sodium hydroxide dosing is performed to maintain a high pH value.

The 90% recovery rate indicates that the feed water of the reverse osmosis system is concentrated 10 times before being discharged. This concentration rate is obviously much higher than that of the conventional reverse osmosis in which the feed water is normally concentrated four times. The reasons for the high recovery rate of HERO are as follows:

(1) Hardness, multivalent ions (such as iron, barium, and strontium), and carbonate alkalinity are thoroughly removed by the pretreatment from the feed water using reverse osmosis; thus, carbonate, sulfate, and hydroxide scales do not exist in the concentrated water.

(2) Because the solubility of silicon increases with the increase in pH under alkaline conditions, the scaling limit of silicon is also significantly raised in HERO. During the HERO operation, the solubility of silicon in the concentrated water could be increased to 350 mg/L without scaling, whereas in the conventional reverse osmosis system, scale inhibitor dosing is carried out to avoid silica scaling once the silicon content of the feed water reaches 25 mg/L.

(3) The propagation of microbes in the reverse osmosis system stops when the pH is above 10.0; therefore, breeding of microbes in the reverse osmosis membranes is prevented.

(4) The charge status on the surfaces of the particles and organic compounds changes under high pH conditions, and the repulsive forces between them and the membranes are enhanced; thus, the tolerance of HERO for organisms and SDI is higher. Organics have been reported to be emulsified or saponified under high pH conditions [1] and are less prone to adhere to reverse osmosis membranes.

After the influence of all the scaling and fouling factors of the reverse osmosis are alleviated or even eliminated by the pretreatment and adjustment of high pH, HERO could obtain a higher recovery rate.

2 Quality and characteristics of the reclaimed water

Based on the long-term monitoring of the water quality and the performance of HERO in the recent three years, we found several characteristics of the product water from the sewage treatment plant as follows:

(1) The quality of the product water from the sewage treatment plant fluctuated greatly. The alkalinity fluctuated in the range of 2 mmol/L to 10 mmol/L, and the conductivity of the feed water from the reverse osmosis fluctuated in the range from 2,000 μS/cm to 3,000 μS/cm. The suspended solid content stayed low from June to September; thus, the performance of the lime coagulation treatment was good, and the turbidity of the product water from the lime treatment was low.

(2) The organics, ammonia nitrogen, and surfactant contents were comparatively high, and so was the chroma. The COD_{Cr} content was in the range from 80 mg/L to 200 mg/L most of the time. The ammonia nitrogen was usually in the range from 50 mg/L to 80 mg/L. Large amount of bubbles and foams existed in both the product water from the lime treatment and the concentrated water

from the reverse osmosis. The anionic detergent content was in the range from 0.08 mg/L to 0.32 mg/L, and the chroma was generally in the range from 50 degrees to 190 degrees.

(3) The suspended solid content also fluctuated greatly, and some materials in the water caused bad performance in the coagulation of the lime treatment and high turbidity of the product water (sometimes higher than that of the feed water, and this case occurred in every season). The temperature of the product water of the sewage treatment plant was generally above 17 ℃ even in winter; hence, the influence of low water temperature on the coagulation performance could be ruled out.

(4) The chloride and sulfate contents were comparatively high. The former was in the range from 200 mg/L to 400 mg/L, and the latter was in the range from 300 mg/L to 500 mg/L.

3 Application of HERO

Because of the poor quality of the reclaimed water, HERO was applied to perform advanced treatment in the power plant in Hebei. The debugging of the HERO system started in September 2009, and reliable operation was achieved after a series of optimizations. Currently, the product water of HERO is directly utilized as the feed water of the make-up water treatment system, which consists of the treatment of conventional reverse osmosis (recovery rate of up to 90% without the dosing of scale inhibitor, fungicide, and reductant) and the mixed ion exchangers. During winter, the product water of HERO was directly utilized for thermal network replenishment. The quality of the feed and product water of HERO in October 2009 are shown in Tables 1 and 2.

3.1 Parameters of the HERO equipment

The HERO system in the power plant consists of two stages between which the ratio is 28:6. Stage 1 is divided into three units where each unit is composed of 28 membrane pressure vessels, and each vessel contains eight Dow BW30-440i reverse osmosis membrane modules (224 membrane modules for every unit). Stage 2 is divided into three columns where each unit is composed of six membrane pressure vessels (identical with those in Stage 1; hence, 144 membrane modules exist for the whole stage). According to the original design, the number of columns in the Stage 2 operation is equal to that of the units in Stage 1. Five degassing pumps (designed output = 325 t/h) are installed on the feed water side, five high-pressure pumps (one is a variable-frequency pump) are installed for each unit in Stage 1 and five for the entire Stage 2. Two security filters with 10-μm filter cartridges are also installed.

3.2 HERO operation

After three years of operation and optimization, we found that under current conditions of the reclaimed water and the configuration of the membrane modules, the product water flux of each unit in Stage 1 changed in the range from 180 t/h to 250 t/h with the change in the water temperature under stable and constant operation. The maximum stable product water flux of each unit in summer was 250 t/h at a concentrated water flux of approximately 84 t/h; hence, we conclude that the recovery rate of Stage 1 was approximately 65% to 75%. The product water flux of Stage 2 was approximately 50 t/h to 60 t/h at a concentrated water flux of approximately 82 t/h (only part of the concentrated water in Stage 1 entered Stage 2, whereas the rest was directly drained off via bypass); thus, we conclude that the recovery rate of the entire HERO was approximately from 76% to 81%. So far, two off-line and several on-line chemical cleaning processes have been conducted in HERO, and the system has maintained a very good operational performance. However, during the periods when the water quality fluctuated because of the effect of the high turbidity of the feed water in HERO caused by the poor coagulation performance of the lime treatment system, the product water flux of HERO sharply decreased.

4 Analysis and discussion of the results

4.1 Influence of alkalinity on HERO

The influence of alkalinity on the HERO system is mainly manifested in two directions: the effect on the weak acid cation exchangers and the influence on the operation of HERO.

(1) Effect on weak acid cation exchangers

As the final barrier before HERO, the weak acid cation exchanger must completely remove the hardness of the feed water. Under current conditions of the water quality, the scaling caused by the leakage of hardness imposes much heavier effect on the product water flux than the contamination of organics; therefore, the hardness of the product water in the weak acid cation exchangers should be strictly controlled and monitored. Currently, the operation standard is set to 10 μmol/L.

Compared with strong acid resins, the weak acid resins can only remove the hardness lower than the alkalinity (called temporary hardness) and are not capable of removing the permanent hardness. Thus, sodium cation exchangers are required to remove most of the hardness to ensure that the remaining hardness (entering the weak acid cation exchangers) is lower than the alkalinity. The quantity of acid dosing in the product water from the lime treatment is also adjusted to keep the alkalinity in an appropriate range and avoid both the scaling of the system before the weak acid cation exchangers caused by high alkalinity and the leakage of hardness caused by low alkalinity. Currently, the alkalinity of the feed water in the weak acid cation exchangers is controlled in the range from 1.2 mmol/L to 1.5 mmol/L, and the hardness is controlled below 1 mmol/L.

(2) Influence on the operation of HERO

Because of the fluctuations in the quality of the reclaimed water, sometimes the alkalinity of the feed water in the weak acid cation exchangers reaches very high levels. Considering that the exchange capacity is normally high and the hardness of the product water in the sodium cation exchangers is controlled to be low, the weak acid cation exchangers show good performance

without losing their effectiveness even if the pH of the product water reaches 8.5 or higher and the product water contained much more carbonate.

For example, we have observed once during the operation of HERO that the inlet pressure of Stage 2 rose sharply from 2.60 MPa to 2.80 MPa. At that time, the alkalinity of the reclaimed water was very high, and the alkalinity of the product water in the sodium cation exchangers reached 9.0 mmol/L, causing high alkalinity in the product water in the weak acid cation exchangers. Thus, the carbonate was not thoroughly removed even though the decarbonators were operating at full load. In such a case, we speculated that carbonate scaling had occurred in the membranes in Stage 2. Therefore, on-line pickling was conducted, and the inlet pressure in Stage 2 was reduced to 2.55 MPa.

From the above example, supplying total hardness-free feed water to HERO is impossible. Scaling of the membranes in Stage 2 would occur rapidly if the system operates under the conditions of high feed water alkalinity and high pH. Therefore, the alkalinity (carbonate content) of the feed water must be strictly controlled.

4.2 Influence of suspended solids on HERO

The applied specialized fabrication process enables the membranes of HERO to endure higher SDI based on our long-term observation of the operation. The main factor that contributes to the high SDI that HERO can deal with should be the colloid and not the suspended solids.

Ultrafiltration devices are not applied in the pretreatment system of HERO. Only variable-pore micro filters of the lime treatment system and high-efficiency filters are utilized for filtering. The SDI of the feed water of HERO is continuously measured, and the results indicate that in most cases, the SDI reaches the limit value of 6.7, which means it is too high to measure. Generally, the solid materials on the diaphragms are visible, and in a few cases, the diaphragms are pierced by suspended solid particles, which shows that suspended solids, colloids, and other SDI-related materials are not effectively removed from the reclaimed water after the lime treatment and high-efficiency filtering. Constant excessively high SDI could impose negative influence on the stability of the HERO operation. In particular, when the content of the suspended materials is high, the product water flux of HERO drops significantly. When the turbidity of the feed water of HERO is below 1NTU, HERO maintains a stable operation even if the SDI cannot be measured. When the turbidity of the feed water exceeds 5NTU, the product water flux begins to decrease significantly; when the turbidity reaches 8NTU to 10NTU because of the “sediment upturning” of the clarifier in the lime treatment system caused by water quality fluctuation, the product water flux drops sharply (e.g., the flux of a unit dropped from 178 t/h to 167 t/h within one day). Although specialized processes of water softening and high pH adjustment are adopted in HERO, fouling of suspended solids is still not well prevented; therefore, the turbidity or the suspended solid content of the feed water of HERO must be strictly controlled.

4.3 Influence of the concentrated water flux on HERO

As the concentrated water flux of the membrane modules becomes lower, the recovery rate becomes higher, and the operational energy consumption is reduced. On the other hand, guaranteeing a certain concentrated water flux is extremely important to maintain a stable operation of HERO. The contaminants in the concentrated water could be effectively entrained and discharged to reduce the contamination of organics and microbes only when the turbulent layer is sufficiently thick. The thickness of the laminar layer could be reduced to weaken the concentration polarization on the membrane surface and thus decrease the content of the insoluble salts and avoid pollution of inorganic precipitate[2]-[5].

HERO did not comply with the requirements of the DOW membrane technical manual because of the specialized fabrication process it applied. The operation of HERO has been continuously optimized; the concentrated water flux of each unit in Stage 1 has been figured out to be above 84 t/h and that of Stage 2 should be above 82 t/h. If the flux does not reach these values, the product water flux of HERO would be affected. Stage 2 consists only of 144 membrane modules. In view of the current water quality, the membrane flux in Stage 2 is reduced to ensure the stability of the operation. A direct drainage pipe for the concentrated water of Stage 1 is added, and part of the

concentrated water is directly discharged through this pipe. With the installation and utilization of the direct drainage pipe, the operational burden of Stage 2 is reduced, and the concentrated water flux in Stage 1 increases; therefore, the stabilities of Stages 1 and 2 are both reinforced.

After the adjustment was performed, sufficient concentrated water flux is guaranteed, and the deposition rate of the contaminants on the membrane surface is effectively lowered (especially when high suspended material content resulting from the fluctuations of the reclaimed water occurred). The operation of the entire HERO is further stabilized.

4.4 Influence of pH on HERO

In the early operational period of HERO, the pH of the concentrated water was controlled from 9.5 to 10.0. In the winter of 2009, we found that the performance of the biochemical treatment of the sewage treatment plant was not sufficiently good because of the low water temperature; thus, the content of the organics of the reclaimed water for the power plant reached a higher level (the COD_{Cr} of the feed water in HERO was in the range from 150 mg/L to 180mg/L), which finally caused the gradual decline of the product water flux. As continuous adjustments were performed, we found that the decline in the product water flux became slower as the pH of the concentrated water increased. Finally, the pH was adjusted to 10.5–10.8, and the product water flux of HERO stopped declining and remained basically stable.

Because of the influence of ammonia nitrogen in water, the pH of the product water of HERO is higher than the pH of the feed water, and the pH of the feed water is higher than the pH of the concentrated water. The limiting pH of the long-term operation of DOW membranes is 11.0. Hence, the pH of the concentrated water was controlled below 10.8 because the pH of the product water was already very close to 11.0 at the same time.

Maintaining a high concentrated water pH has been shown to reduce effectively the effect of organics and maintain the product water flux of HERO.

4.5 Analysis of the results of chemical cleaning

At the end of 2010, an on-line chemical cleaning was conducted on HERO. The process included ①pickling (HCl pH=2), ②acid soaking, ③water rinsing, ④alkaline cleaning (NaOH + sodium dodecyl benzene sulfonate, pH=12), ⑤alkaline soaking, ⑥water rinsing, and ⑦re-pickling. Measurements by the inductively coupled plasma atomic emission spectroscopy were conducted to determine the contents of the different elements in the effluent, and the results are shown in Table 3.

Table 3 Contents of different elements in the effluent of chemical cleaning (mg/L)

Coefficients	Oxides	Effluent of pickling, 3rd column	Effluent of alkaline soaking, 3rd column (acid dosed and filtered)	Effluent of alkaline soaking, 2nd column (acid dosed and filtered)	Effluent of alkaline soaking, 4th column (acid dosed and filtered)	Effluent of alkaline soaking, 4th column (acid dosed and filtered)
1.21	K_2O	7.801	3.062	2.525	3.389	3.54
1.35	Na_2O	118.5	994.1	752.0	1001.0	984.3
1.40	CaO	9.610	0.2761	0.5505	20.16	7.923
1.67	MgO	2.782	0.0207	0.0350	1.351	2.114
1.28	CuO	0.0138	0.0015	0.0130	0.0172	0.0142
1.43	Fe_2O_3	259.1	10.73	11.76	40.29	26.19
1.25	ZnO	1.414	0.0002	0.0375	0.1333	0.0426
2.14	SiO_2	199.9	108.7	87.44	168.7	157.4
1.89	Al_2O_3	6.863	0.9640	0.6621	1.602	1.298
1.67	TiO_2	4.413	—	0.8741	3.507	2.398
2.50	SO_3	4.856	158.6	111.4	189.7	186.3
2.29	P_2O_5	0.933	9.233	9.195	10.87	17.31
1.58	MnO_2	1.847	0.0248	0.0295	0.1330	0.0519

The data in Table 3 indicate the following:

(1) P_2O_5 (or phosphorus-containing substance on the membrane surface) dissolved under alkaline conditions. After the acid dosing was carried out, part of P_2O_5 precipitated and was filtered out.

(2) From the data of the pickling and alkaline cleaning in the third column, most of the iron still existed in the form of ions. The colloidal iron content was low, indicating that iron leakage from the weak acid cation exchangers occurred.

(3) From the data in the third column, the total silicon content on the membrane surface was higher than 300 mg/L, indicating that the concentrated water flux was not sufficient, and silicon deposition occurred. Heavy deposition of iron silicate was also observed either because of the low pH or the excessively high iron content.

(4) From the data in the third and the fourth columns, the calcium content of the feed water of HERO was high, indicating that calcium was not effectively removed by the weak acid cation exchangers. The water rinsing in the fourth column after pickling was not thorough, and re-pickling after alkaline cleaning was necessary.

(5) From the data in the fourth column, part of the iron in the fourth column had already precipitated when alkaline cleaning was performed.

4.6 Advantages of HERO in reclaimed water treatment

For the conventional reverse osmosis system, periodic chemical cleaning is necessary to deal with the reclaimed water to mitigate the effect of organic matters and other fouling substances. In addition, ultrafiltration devices must be utilized; thus, problems of higher space demand, higher operational cost, and ultrafiltration fouling emerge. Compared with the conventional reverse osmosis system, the operation stability of HERO is much higher, the frequency of chemical cleaning is much lower, and the recovery rate is higher. In addition, no ultrafiltration system is needed. Therefore, the space demand and operational cost could be greatly reduced.

5 Conclusions

(1)The HERO system has shown strong advantages in treating reclaimed water with poor quality. It could be operated under conditions of high organic matter content and high SDI, and could achieve obvious economic benefits in terms of reclaimed water treatment.

(2)The alkalinity, content of suspended solids, concentrated water flux, and pH were the most significant factors that influenced the operation of the HERO system.

(3)The hardness and phosphorus, silicon, and iron contents were the most significant factors that influenced the fouling of the HERO system. These parameters of the feed water in HERO must be strictly controlled.

Department of Chemistry, Loyola University of Chicago, Chicago, IL 60626, United States

fengyanliu8105@sina.com

Keywords: Infrared absorption method, IN718, ultra low sulfur.

Abstract. The paper introduces an experimental process on measurement of ultra low sulfur in IN718 by using infrared carbon sulfur analyzer. The experimental data shows that, infrared absorption method can be used to analyze and measure the ultra low sulfur in IN718, and the precision and accuracy of this method meets the requirement of ASTM E l019-2000. It can be concluded that it is a feasible method in practice.

Introduction

Superalloy INCONEL 718（IN718）has been applied in making aircraft engine for half a century. Since 1960s, after INCO Huntington Alloys (now Special Metals Co．)has been invented and applied for manufacturing turbine parts, IN718 has become the most widely applied nickel-base Superalloy in the development history of aircraft engines. The unique alloy component design of IN718 allows it to have excellent comprehensive performances, such as high strength, creep resistance, and fatigue endurance. Many parts of modern aircraft engines, such as turbine discs, blades, cartridge receivers, axles, stators, obturage, supporters, pipelines, fastening pieces, are made from IN718.

In recent years, along with the increasingly higher demand on performance and efficiency of turbine engines, the working temperature of engines has been increasing constantly. IN718 alloy materials with high degree of cleanliness are used for manufacturing the key parts of engines [1]. IN718 alloy materials with high degree of cleanliness have a very strict demand on chemical components and their sulfur contents have to be controlled at S:1μg/g~10μg/g. Since sulfur in IN718 is taken as impurities, which may easily become the occurrence place and extending channel of endurance cracks. In addition, these impurities may become crystallization nuclei, which may lead to performance degradation of alloys[2][3]. Therefore, accurate analysis of the content of Ultra-low sulfur in IN718 has become an important link in the quality control process.

Currently, the standard methods of using infrared absorption to measure the sulfur content in alloys mainly include ISO 15350[4], ASTM E1019[5], etc. However, the analytical range of above methods (S ＞5μg/g) can not meet actual demand.

To meet the requirements of the market on higher quality and diversified products of IN718, the application of the Ultra-low sulfur （S:1μg/g~10μg/g）IN718 will become a development trend. Accordingly, the corresponding analytical technology should be developed for providing support.

By selecting infrared carbon sulfur analyzer as analytical instrument, and through experiments on relevant factors such as combustion conditions and blank control, this study has worked out the best analyzing conditions of sulfur（S:1μg/g~10μg/g）in IN718 and established an analytical method. The method has been used for measuring ultra-low sulfur, and the result is satisfactory.

Selection of analytical and testing conditions

Principle of analyzing Ultra-low sulfur by using infrared absorption method

The sample is placed in a ceramic crucible, and the high-frequency furnace is supplied with oxygen. After combustion in high temperature, the sample is melting, and the sulfur in sample, under the effect of carrier gas, generates sulfur dioxide. After the infrared pool absorbs the infrared energy

with specific wave length, we can calculate the integral value of sulfur dioxide according to the difference of the infrared energies before and after the absorption, and with pure oxygen as reference, and thus calculate the percentage composition of sulfur.

Sample preparation and sample quantity

Samples should be prepared into crumb shape, as fine and small as possible, and they should not be prepared into lump. Special processing and sample container must be used during processing procedure. The processed samples should be immediately put into a grinding mouth bottle so as to avoid greasy dirt and other impurities. When necessary, ether or acetone could be used for cleaning the samples, and then the absolute ethyl alcohol is used to rinse samples and dry it.

Due to the low sulfur content in IN718, ($S \leq 10\mu g/g$), if sample quantity is too less, the sulfur in the sample loses its representativeness, if sample quality is too much, the combustion will not be complete. Usually, the sample of 0.500g will be taken for measurement.

Selection of fluxing agents and their dosage

By examining the effect of various fluxing agents (such as tin grain, tungsten grain, and pure iron) on measurement result, we can conclude that, the different fluxing agents have different effects on the measurement process.

When adding tin grain, the pollution degree of combustion furnace and gas circuit will be increased notably. By selecting tungsten grain as fluxing agent, it can react with oxygen under the temperature of 400 ℃, and generates tungsten trioxide. The oxidation process will release large amount of heat, which immediately raises the temperature of samples in it and causes it to react. Meanwhile, volatilization of tungsten trioxide raises the speed of diffusion of the sulfur, which is conductive to the release of sulfur dioxide and the measurement of sulfur.

Ferric oxide, the product of combustion of iron, is featured with magnetism, and under the condition of high frequency, it can keep the combustion product in a meltdown state, which allows the complete release of SO_2. The disadvantage of pure iron fluxing agent is its high S blank value, usually $S \approx 0.0005\%$.

By summarizing the experiment result, this study selects composite fluxing agents: 2.000g tungsten-tin grain + 0.500g iron.

Experiment on selection of instrument parameters

Gas circuit may have a little amount of remaining SO_2 due to its absorption effect, which may cause variation of analysis results. It is necessary to use oxygen to blow and wash the gas circuit. If the time of the oxygen washing is too short, the effect is small; if the time of oxygen washing is too long, large amount of oxygen will be consumed. Therefore, the proper washing time should be identified. The oxygen washing time of this study is identified as 10 seconds.

The analysis result is directly proportional to the integral value of area of dissolution curve. The integral value of area involves the comparison level of analysis (also called cut-off level). If the cut-off level is set too low, it may cause the time extension of the analysis, and thus affect the blank value in the system. As a result, the precision of the analysis will be compromised. If the cut-off level is set too high, it may shorten the analysis time, which may cause incomplete combustion and incomplete collection of data signal. As a result, it may affect the precision and accuracy of the analysis result.

In the measurement of ultra-low sulfur in IN718, the cut-off level has relatively great influence on the result of the measurement due to relatively low releasing curve. The cut-off level of this study is set to be 4.

Complete collection of measured signals within the shortest analytical time is an indispensable condition for ensuring the precision of analysis. If the preset minimal analytical time is too short, it is likely to cause the loss of partial measured signals, and thus the reduce the analysis precision; if the preset minimal analytical time is too long, it may introduce noise signals, and cause relative high analysis result. It can be seen from the ideal releasing curve illustrated in Figure 1 that, the measured signals are completely collected after 40 seconds of analysis. Therefore, the minimal analytical time is set to be 40 seconds.

Purpose of selecting combustion conditions

The purpose of selecting combustion conditions is to allow the complete combustion and release of sulfur in the samples. Firstly, the ideal releasing curve must occur (see Figure 1). Meanwhile, after meltdown, the bottom of the crucible pot is smooth, and unmelted sample is not found in the molten mass (see Figure 2). If the analytical conditions are not correctly set, the multi-peak curve and trailing curve may occur, which may affect the analytical precision.

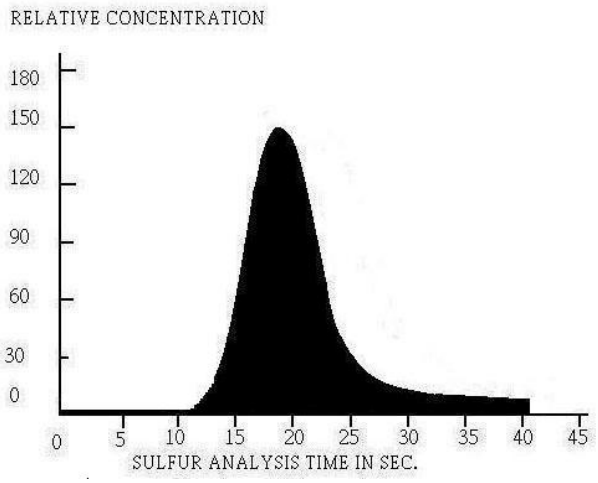

Figure 1 Ideal Releasing Curve

Figure 2 Smooth Bottom of Crucible Pot after Meltdown

Blank Control

If the measurement of ultra-low sulfur content does not deduct blank value, it may cause large error. The contents of ultra-low sulfur（S:1μg/g~10μg/g）in IN718 is in the same order of magnitudes with the sulfur content of fluxing agent and it is important to deduct blank value. Therefore, the measurement and deduction of blank values is a key technology to ensure the precision and accuracy of measurement of ultra-low sulfur in IN718.

Sources of blank values

Blank values mainly come from oxygen, crucible, fluxing agent, combustion system, instrument noise, etc.[6][7].

High purity oxygen is used and the trace amount of remaining SO_3 and SO_2 are absorbed by Soda asbestos. After measurement, the system blank in oxygen S＜0.3μg/g.

For the measurement of ultra low sulfur in IN718, blank processing of crucible is very important. This paper uses LECO special crucible, and it is heated in muffle furnace at 1000℃ for 4 hours, and cooling down to 200℃, and placed into dryer for storage. Before use, it needs to be heated in the muffle furnace at 1000℃ for 15 minutes and then taken out. After its color turns into white, the sample and the fluxing agent are placed into a processed crucible and they are kept in muffle furnace or resistance furnace at 420℃ for 5～10min. After processing, the blank value can be effectively reduced, and after the measured blank value S＜0.3μg/g.

Blank value brought by combustion system is caused by the imbalance of the adsorption and desorption of the whole system to sulfur. When the adsorption exceeds desorption, the measured result is relatively too low; when desorption exceeds adsorption, the measured result is relatively too high. Usually, preburning of 10 waste samples could reach the balance between adsorption and desorption.

It can be seen from the releasing curve (vertical coordinate is the relative concentration), the peak value of ultra-low sulfur release is usually no more than 200. Instrument noise may affect the measuring result. Usually it is reduced by selecting the above mentioned cut-off level and minimal analytical time.

In tungsten-tin grain fluxing agent, the sulfur blank S≈1μg/g. In pure iron fluxing agent, the sulfur blank S≈5μg/g.

Measurement of total blank value

There are three methods to measure blank values: cycle measurement[8], direct measurement[9] and indirect measurement[9].

Method of total blank value deduction

The total blank value measured by using cycle measurement method is entered into blank value field, and the instrument will make a automatic deduction.

Analysis and discussion of the experiment

Measurement of total blank value

This study uses cycle measurement method to measure the total blank value of sulfur[8].

Two standard substances of AR 673 [S:0.0011±0.0002] and LECO 502-348 [S:0.0008±0.0001] are selected, and 2.000g of tungsten-tin fluxing agent and 0.500g of pure iron fluxing agent are put into crucible. Parallel measurements of samples are conducted for 9 times according to the operation procedure. And the measurement result of the second time is illustrated in the Table 1.

Table 1. Second measurement result of the blank value %

	Blank value
Measured value	0.00010, 0.00009, 0.00013, 0.00011, 0.00008 0.00012, 0.00014, 0.00012, 0.00010
Average measured value	0.00011
Standard deviation	0.0000194
RSD	17.6

It can be seen from table 1, RSD=17.6, and the total blank value is stable. The total blank value of S:0.00011% is entered into the blank value field of the instrument, and the automatic deduction will be performed by the instrument.

Experiment on precision and accuracy

In order to examining the precision and accuracy of analysis, a standard substance AR 673(S:0.0011±0.0002%) calibration instrument is selected. The calibration result is illustrated in the Table 1. The measurements for additional three types of standard substances of ultra-low sulfur, and parallel measurement of each standard substance will be performed 9 times according to analytical procedure. The analytical result is illustrated in table 3.

Table 2 Result of Instrument Calibration

	AR 673
Standard value	0.0011±0.0002
Measured value	0.00105, 0.00112, 0.00109, 0.00115, 0.00107 0.00103, 0.00108, 0.00121, 0.00110
Average measured value	0.0011
Standard deviation	0.000055
RSD	4.96

Table 3 Precision and accuracy of standard substance measurement %

Standard substance	LECO 502-348	YSBC20171	Pure iron 4#
Standard value	0.0008±0.0001	0.00055	0.00045
Measured value	0.00089, 0.00080, 0.00077 0.00075, 0.00099, 0.00081 0.00088, 0.00093, 0.00083	0.00043, 0.00039, 0.00052 0.00050, 0.00040, 0.00042 0.00048, 0.00051, 0.00055	0.00037, 0.00034, 0.00038 0.00039, 0.00049, 0.00046 0.00035, 0.00041, 0.00037
Average measured value	0.00085	0.00047	0.00040
Standard deviation	0.000079	0.000058	0.000050
RSD	9.24	12.3	12.5

The experiment data from Table 2 and Table 3 shows that, the measured value of each analytical result is basically consistent with standard value of standard substance. Furthermore, the different between average value and standard value can meet the requirement of ASTMEl019[5] on analytical precision.

Sample analysis

Parallel measurements of three IN718 samples are performed 9 times separately, and the results are illustrated in the Table 4.

Table 4 Results of the IN718 Sample Measurement

Sample No.	1#	2#	3#
Measured value	0.00115, 0.00131, 0.00100 0.00101, 0.00121, 0.00098 0.00135, 0.00125, 0.00121	0.00066, 0.00077, 0.00087 0.00090, 0.00056, 0.00066 0.00088, 0.00075, 0.00074	0.00035, 0.00044, 0.00050 0.00028, 0.00040, 0.00036 0.00031, 0.00036, 0.00043
Average measured value	0.00116	0.00075	0.00038
Standard deviation	0.000138	0.000115	0.000068
RSD	11.9	15.4	18.0

It can be seen from the data of the Table 4, relative standard deviation is less than 20%, and the analytical precision is relative high, which demonstrates that, the infrared absorption method is a feasible method for analyzing ultra-low sulfur in IN718.

Sulfur Detection Limit

Total blank value of S:0.00011% is entered into the blank value field of the instrument, and the automatic deduction will be performed by the instrument. Then, without adding sample, fluxing agent is added to measure the sulfur content by simulating the analytical conditions, and it is called the measurement of blank value.

Table 5 Measurement of Blank Value

	Measurement of Blank value
Measured value	-0.00002, 0.00003, 0.00002, -0.00003, -0.00003 0.00000, 0.00003, -0.00003, 0.00004
Measued averave blank value $\overline{X}$	0.000001
Standaard diviation S	0.0000293

Sulfur detection limit $= \bar{X} + 3S = 0.0000011 + 3 \times 0.0000293 = 0.00009\%$. It can meet the analysis requirement of ultra-low sulfur（S:0.0001%~0.0010%).

Standard Addition Test

Recovery test is conducted by using standard addition method. Standard substance AR-673 [S:0.0011±0.0002%] is added into 0.200g of 2#IN718, and 0.5000g analytical quantity is entered. The test is performed according to the best condition identified above and the test result is illustrated in the Table 6.

Table 6. Recycled Volume and Recovery Rate

Sn.	AR-673 (S:0.0011±0.0002%) Add on Amount[g]	Added sulfur [μg]	Measured value [%]	Sulfur content [μg]	Recycled Sulfur [μg]	Sulfur recovery rate [%]
1	0.100	1.10	0.00054	2.70	1.20	109.1
2	0.200	2.20	0.00075	3.75	2.25	102.3
3	0.300	3.30	0.00096	4.80	3.30	100.0
4	0.400	4.40	0.00105	5.25	3.75	85.2
5	0.500	5.50	0.00137	6.85	5.35	97.3

In the table 6, the sulfur content in 0.200g of high strength stainless steel is calculated. According to the average value of 0.00075% of 9 times of measurement of 2#IN718 sample analysis, it is calculated as follows: $0.200g \times 0.00075\% = 1.5 \times 10^{-6}g = 1.5\mu g$;

It can be seen from table 6, the recovery rate is between 85% and 110%, which indicates that the accuracy of this method is relative high.

Conclusion

By using Carbon- Sulfur Analyzer, the infrared absorption method is used to analyze ultra-low sulfur, and the sample quantity is 0.500g. Total blank value of sulfur is measured by using cycle measurement method, and the result of 0.00011% is entered into the blank value field of the instrument to automatically deduct the blank. According to the measurement result of IN718, the data is processed. The RSD is between 7% and 17%, and the detection limit of this method is 0.00009%. The analysis result of this method meets the requirement of ASTM E 1019 on analysis precision and accuracy, and it is feasible in practice.

The Synthesis and Characterization of Polyphenylene Vinylene (PPV) Derivatives with Alkoxy Branched Chains

Zhang Xiao-zhoua, Wang Yu-weib

College of Materials Science and Engineering, Qiqihar University, Qiqihar, 161005,China

aemail: zhangxzh-n@163.com, bemail:wyw032378@163.com

Keywords: poly(p-phenylene vinylene); dehydrochlorination; luminescence polymer; fluorescence spectra

Abstract. Polyphenylene vinylene derivatives with various alkoxy branched chains, including PMOBOPV,PMOCOPV,iso-PMOCOPV and PMODOPV,were synthesized via a dehydrochlorination route,and characterized by FTIR,HNMR,DSC,TGA,UV-Visible and fluorescence spectroscopy. The result indicated that as-prepared polymers were of remarkable thermal stability and solubility in common solvent with the maximum UV absorption peak at ~492nm and light emission at ~555 nm.

Introduction

Conjugated organic polymers are a class of materials which possess not only the electrical and optical properties of traditional semiconductors, but also the mechanical and processing advantages of polymers. Among these, polyphenylene vinylene or PPV is studied intensively due to its strong photoluminescence (PL) at a wavelength ~2.2eV, which are very useful in photoelectronic applications, such as light emitting diode, first reported by Burroughes in 1990[1-3]. However, PPV with an unfunctionalized form is not readily put in liquid form, either by melting or by dissolving volatile solvents in a process to fabricate PPV-based films and fibers because of strong interactions between chains[4]. A resolution for the intractability is to add alky or alkoxy side chains to PPV backbones, which reduces the melting point of PPV and makes it more compatible with organic solvents. By increasing the length of side chains, the PL intensity can be enhanced because the long side chain prohibits the mobility of excitons towards recombination centers. Additionally, groups introduced in 2- and 5- positions with different structures decrease the crystallization of polymers and morphological defects[5]. However, it remains challenging to prepare PPV derivatives with a good solubility, controllable molecular weight (MW) and narrow MW distribution. Heeger et al. reported a dehydrochlorination process to synthesize soluble copolymer of PPV with short steps and facile operations[6].

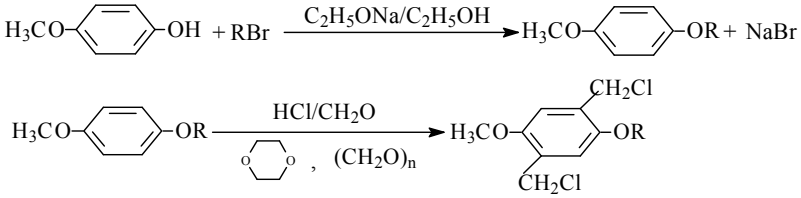
In this work, four PPV derivatives were prepared by the dehydrochlorination of p-hydroxyanisole, which consist of a methoxyl group in position[2]and different alkoxy substitutes in position [5]. The influence of reaction conditions on the polymer yield is discussed. In this work, absolute AlCl3 was used as a Lewis acid catalyst to improve the yield and selectivity of chloromethylation. Moreover, the impact of alkoxy side chains on the propertie of as-prepared polymers, such as solubility, thermal stability and luminescence, are investigated.

Experiment

Measurement.1HNMR spectra were collected on a Bruker Avance 400 spectrometer with chloroform-d as solvent and tetramethylsilane as internal standard. FTIR spectra were recorded on a PerkinElmer Spectrum One B spectrometer. Thermogravimetric analyses (TGA) were conducted on a PerkinElmer Pyris Diamond thermogravimetric analyzer in a temperature range from 20 to 500 °C at the heating rate of 20 °C/min and calcined Al2O3 powder as the standard reference under nitrogen atmosphere. The molecular weight of PPV derivatives was measured by GPC (Waters 1515

GPC instrument, using styragel-1000 columns and tetrahydrofuran as a mobile phase). UV-Visible spectra were obtained on a Perkin-Elmer Lambda 35 Spectrometer in chloroform solution. Photoluminescence spectra were measured by a Hitachi F24500 fluorescence spectrometer in chloroform solution.

Reaction Equitions.



(R=n-C4H9, n-C8H17, iso-C8H17, n-C12H25)

Materials 1-methoxyl-4-alkoxy benzene(I). 0.05 mol p-hydroxyanisole and CH3CH2ONa/CH3CH2OH solution in a 250 ml were added into a four-neck flask (250 ml) equipped with a condenser and stirrer, and reacted at 80 °C in N2 under reflux for 90 min. A yellow solution was obtained and cooled to 20 °C. Then bromoalkane (n-Butyl bromide, n-Octyl bromide, i-Octyl bromide or n-Dodecyl bromide) were added dropwise into the yellow solution and reacted at 80 °C in reflux conditions for 5 h. After reaction, a reduced pressure distillation was used to separate EtOH from the red-brown solution obtained. The remnant were dissolved in 15% KOH solution and then extracted by ethyl ether. The oil layer was washed by 30 °C distilled water twice, heated to evaporate ethyl ether and dried by absolute MgSO4. The product I obtained was a yellowish solid in room temperature. The yield are 48, 57, 76 and 62%(wt) while using n-butyl bromide, n-octyl bromide, i-octyl bromide or n-dodecyl bromide to conduct the substitution reaction.

1,4-dichloromethyl-2-methoxyl-5-alkoxyl benzene (II). To as-synthesized I in a ice bath was added 50 ml 1,4-dioxacyclohexane, certain amount of formaldehyde, concentrated HCl and paraformaldehyde (the molar ratio of I, formaldehyde and concentrated HCl was ~ 1:10:10). The mixture was transferred to a four-neck flask, refluxed at 90 °C in the presence of absolute AlCl3 for 5 h, and then cooled to room temperature. A rotatory evaporation process was used for the removal of 1,4-dioxacyclohexane. The remant was treated by crystallization and a followed recrystallization in a mixture of n-heptane and ice methanol with a volume ration of 1:1. The white II powder could be obtained after separated from the solution by filter, washed by ethanol and dried in vacuums. The yield were 58,52,65 and 61%(wt) for 1,4-dichloromethyl-2-methoxyl-5-n-butyloxybenzene,1,4-dichloromethyl-2-methoxyl-5-n-Octyloxybenzene,1,4-dichloromethyl-2-methoxyl-5-i-octyloxybenzene,and1,4-dichloromethyl -2-methoxyl -5-dodecoxybenzene, respectively.

Poly (2- methoxyl-5-alkoxyl p-phenyl vinylene)(III). To a solution of 0.0025 mol II in 10 ml tetrahydrofuran(THF), was added dropwise a fresh potassium t-butoxide THF solution [(CH3)3COK:THF=1:1.6 (mole ratio)] in a three-neck flask (25 ml). The mixture was refluxed with N2 protection at 66 °C for 2 h. The color of solution changed gradually from colorless to yellow and to dark orange. Then 10 ml methanol was added to the mixture and reacted for 10 min. THF was removed by rotatary evaporation, and the III powder was washed successively with absolute ethanol and distilled water and separated by vacuum filtrations. The yield is 49% for poly (2-methoxyl-5- Butoxyl p-phenyl vinylene) (PMOBOPV, orange red), 54% for poly (2- methoxyl-5-octoxyl p-phenyl vinylene) (PMOCOPV, orange red),56% for poly (2- methoxyl-5- isooctoxyl p-phenyl vinylene) (iso-PMOCOPV, red) and 51% for poly (2- methoxyl-5- dodecoxyl p-phenyl vinylene) (PMODOPV, dark red).

PMOBOPV：1 HNMR，δ1.29 ~ 1.63（4H，methene），δ0.97（3H，methyl），δ4.68（2H，ethylene），δ6.98（2H，aromatic protons），δ7.26（3H，-OCH3），δ3.89（2H，-OCH2）；PMOCOPV：1 HNMR，δ1.22 ~ 1.80（12H，methene），δ0.88（3H，methyl），δ4.57（2H，ethylene），δ6.86（2H，aromatic protons），δ7.15（3H，-OCH3），δ3.89（2H，-OCH2）；iso-PMOCOPV:1 HNMR，δ1.18 ~ 1.80（9H， methene），δ0.82（6H，methyl），δ4.66（2H，ethylene），δ6.83（2H，aromatic protons），δ7.14（3H，-OCH3），δ3.69（4H，-OCH2）；PMODOPV:1 HNMR，δ1.26 ~ 1.77（18H，methene），δ0.89（3H，methyl），δ4.55（2H，ethylene），δ6.83（2H，aromatic protons，δ7.26（3H，-OCH3），δ3.92（2H，-OCH2）.

Results and Discussion

Substituent groups and solubility. To PPV derivatives with alkoxyl branched chains, the length of branched chains is helpful for the enhancement of solubility. Compared with PMOBOPV, PMOCOPV, and iso-PMOCOPV, PMODOPV (containing dodecoxyl groups) could be dissolved into THF faster. Since branched chains decrease the degree of order of the main chain in a polymer; asymmetric branched chains diminished the interaction between chains of PPV macromolecules, which contribute to a higher solubility of polymers in solvents. Therefore, the larger solubility of PMODOPV is attributed to its longer branched chains (dodecoxyl groups), worse symmetry due to different lengths of branched chains on 2-and 5- positions and lower crystallinity among four polymers. Additionally, it was found that four polymers could be dissolving in other solvents such as chloroform, tetrachloromethane, and toluene.

Molecular weight of polymers. GPC analysis revealed that the number average molecular weight (Mn) and weight average molecular weight (Mw) of the polymers are ~50000 with a polydispersity index (PDI) ~1 as shown in Table1. Such uniform molecular weight distributions are helpful for the fabrication of optical film.

Thermal stability of polymers. The thermogravimetric (TG) curves of four polymers are shown in Fig. 3. iso-PMOCOPV and PMOCOPV have similar TG curves with an initial thermo- decomposed temperature ~328 °C, which is close to that of PMOBOPV (~333 °C). By contrast, the initial thermo- decomposed temperature of PMODOPV is 159 °C, much lower than others. It implies that the increasing length of substituent groups detrimentally affects the thermal stability of polymers.

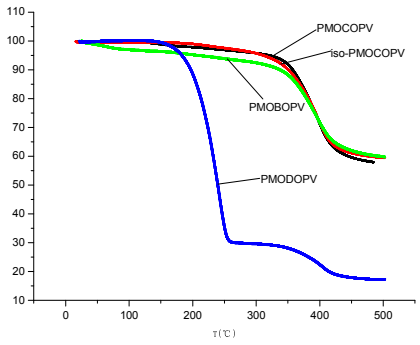


Table1. Molecular weight of polymers

Polymer	Mn	Mw	PDI
PMOBOPV	47214	47532	1.001
PMOCOPV	43339	48013	1.108
iso-PMOCOPV	55374	57362	1.036
PMODOPV	49215	51595	1.048

Fig.3. TG curves of different polymers

UV/visible absorption spectrum. The absorption peaks of UV/visible of polymers are determined by the length of conjugated chains and the electron effect of substituent groups in the benzene ring. Different side chains vary the bandgap, electron affinity, and ionization potential of polymers. For example, alkyl group, alkoxy group and other electron-donor group in the benzene ring can decrease the bandgap of PPV and cause an absorption redshift8. In this work, the maximum absorption is at 438 nm, 492 nm, 487 nm, and 492 nm for PMOBOPV, PMOCOPV, iso-PMOCOPV

and PMODOPV, respectively. Such an observation is consistent to the previous report that the absorption peak of PPV shifts from 420 nm (without substituents) to 490 nm (with alkoxy substituents).9These shifts are explained as being a result of the inductive electron withdrawing properties of the fluorine substitution leading to reduced electron density in the conjugated polymers and leading to an increase in the HOMO-LUMO band gap.The number of carbon atoms has no effect on the absorption spectrum if the side chain contains more than 5 carbon atoms.

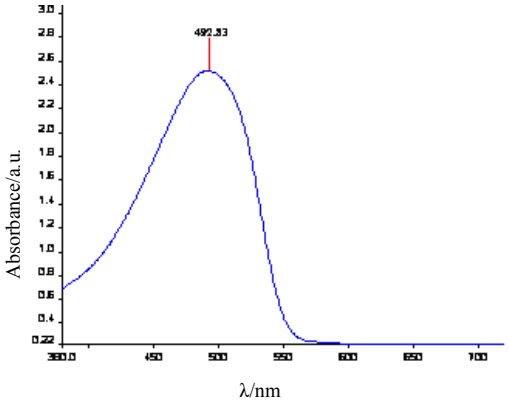

Fig.4. UV-Visible absorption spectrum of iso-PMOCOPV

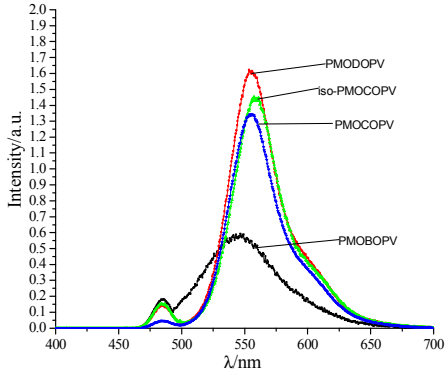

Fig.5. PL spectra of different PPV derivatives

Photoluminescence. The PL spectra of the dilute solutions of PPVs are shown in Fig. 5. The maximum emission of PMOBOPV occurs at 548 nm. PMOCOPV, iso-PMOCOPV and PMODOPV exhibit similar PL spectra with maximum emission at ~555 nm. Such a result indicates that the length of branched chains has little effect on the PL spectra of PPV with alkoxy substituents. Compared with the maximum emission (~540 nm) of PPV without substituents,6 red shifts were observed in PL spectra as shown in Fig. 5. It could be resulted from two reasons: the first, these PPV derivatives have longer conjugated chains. The dislocation π electrons can be excited by a relatively lower energy and cause red shifts in PL spectra; the second, an alkoxy substituent is of lone pair electrons and the π electron cloud approximately parallels a π orbit of the benzene ring. Such a structure is helpful to share π-electron conjugation and expand conjugated π systems, which causes red shifts in PL spectra.

Conclusions

In this work, four polymers, PMOBOPV, PMOCOPV, iso-PMOCOPV and PMODOPV, were synthesized by a strong base induced dechlorination process and characterized. The optimal conditions were 16:1:7 in the molar ratio of AlCl3/double ether/paraformaldehyde for the dechlorination reaction, and 2.6:1 in the ratio of potassium tert-butoxide/chlorben for the polymerization reaction. These PPV derivatives reveal good thermal stability, solubility in common organic solvents, and strong absorption and emission properties.

Keywords: preparation, characterization, method, graphene oxide

Abstract. The graphene oxides were prepared form graphite by thermal expansion and ultrasonic dispersion. The structure of graphene oxides was characterized by Fourier transform infrared spectrometer (FTIR), scanning electron microscope (SEM), X-ray diffraction (XRD) and Raman spectra. The difference of structure of graphene oxides by two preparation methods was compared. The measurement of FTIR and XRD showed the graphite was completely oxidized. The graphene oxide prepared by thermal expansion would lose large number of active functional groups, such as hydroxyl, carboxyl group, et al. However, the graphene oxide prepared by ultrasonic dispersion can retain these active functional groups. These active functional groups will be benefit to chemically modify the graphene oxides and prepare the polymer/graphene nanocomposites.

Introduction

Graphene sheets have attracted tremendous attention from both the theoretical and experimental scientific communities in recent years, due to its unique physical properties like superior mechanical properties, flexibility, high specific surface area, extraordinary thermal conductivity and excellent electronic transport properties [1,2].

Graphene, as the thinnest material known in the universe, is a single-atom-thick sheet of sp2-bonded carbon atoms in a hexagonal two-dimensional lattice. The promising mechanical, electrical, optical, thermal and magnetic properties of graphene have "led to the creation of a new and exciting 'laboratory' for the study of fundamental science." Graphene as a nanofiller, may be preferred over other conventional nanofillers. It has found applications as the key filler among the carbon-based nanofillers owing to high surface area, aspect ratio, tensile strength, thermal conductivity and electrical conductivity, flexibility, transparency [3,4].

When the graphene was dispersed in polymer as nanofiller, the polymer/graphene nanocomposites show superior mechanical, thermal, gas barrier, electrical and flame retardant properties compared to the neat polymer. However, the improvement in the physicochemical properties of the polymer/graphene nanocomposites depends on the distribution of graphene layers in the polymer matrix as well as interfacial bonding between the graphene layers and polymer matrix. Interfacial bonding between graphene and the host polymer dictates the final properties of the graphene reinforced polymer nanocomposite [4-8].

It is well known that the graphene is not compatible with organic polymers and it is difficult to form polymer/graphene nanocomposites. The graphene are heavily oxygenated to prepare the graphene oxide sheets. In contrast, the graphene oxide can alter the van der Waals interactions significantly and be more compatible with organic polymers because of its bearing hydroxyl, epoxide, diols, ketones and carboxyls functional groups [9-12]. For this reason, the graphene oxide has attracted considerable attention as a nanofiller for polymer nanocomposites. The surface chemical modification of graphene is an essential step for obtaining a molecular level dispersion of individual graphene in a polymer matrix [13].

Several preparation methods of graphene oxide were developed and researched in recent years, such as ultrasonic dispersion, thermal expansion, mechanical stripping, et al. The structure and properties of graphene oxide are different by those preparation methods. The structure and properties of graphene oxide will effect the surface chemical modification and the dispersion in the organic polymers. Then, it is important that the structure and properties of graphene oxide by different preparation methods are characterized. In this paper, the graphene oxide was prepared by ultrasonic dispersion and thermal expansion, its structure and properties were measured.

Experimental

Materials

Graphite, concentrated sulfuric acid, hydrogen peroxide, hydrochloric acid, potassium permanganate, sodium nitrate and barium chloride were supplied by Guangzhou Chemical Reagent Co., Ltd. N-methylpyrrolidone(NMP), N,N-dimethyl-formamide(DMF), acetone, dimethylbenzene were purchased from Shenzhen Baoyu Chemical Reagent Company. All the materials in this study were used as received without further purification.

Preparation of graphite oxide

The concentrated sulfuric acid（115ml，98%）and sodium nitrate（$NaNO_3$, 2.5g）were added in the beaker and were stirred under ice bath. Then the graphite was added when the temperature was below 5℃ in system and still stirred 30min. The potassium permanganate (15g) was slowly added and still stirred 60min under ice bath. The beaker was placed in constant temperature water bath at 40℃ and still stirred 30min, and the 220mL deionized water was added in the beaker. The temperature was controlled under 90℃. The hydrogen peroxide (5%，35ml）was added, and the color of solution was changed from brown black to light brown. The product was filtered and washed by 5% hydrochloric acid until the SO_4^{2-} didn't detect by barium chloride solution. Then the product was washed by deionized water and dried in the oven at 50℃.

Preparation of graphene oxide

The graphene oxide was prepared by ultrasonic dispersion and thermal expansion. The first method, the graphite oxide was placed in pipe furnace under nitrogen protection, and the temperature rise to 1050℃ for 1-2min. The graphene oxide was kept in the oven at 50℃. The second method, the graphite oxide was ultrasonic dispersed in water N-methylpyrrolidone (NMP), N,N-dimethyl-formamide(DMF), acetone and dimethylbenzene .

Measurement

The graphite oxide and graphene oxide were measured by Fourier transform infrared spectrometer (Analect RFX-65A, FTIR), scanning electron microscope (Hitachi S-3000H, SEM), X-ray diffraction (XRD-6100) and Raman spectra (Advantage 532).

Results and discussion

The FTIR spectra of graphite oxide is shown in Figure 1, There existed evident absorption peaks of C=O at 1720cm-1. The absorption peak of OH was at 3600 cm-1 and 1400cm-1. The stretching vibration peak of C-OH was at 1214cm-1, and the characteristic peak of C-O was at 1053cm^{-1}. The results in Fig. 1 showed that the graphite was oxidized.

The XRD of graphite and graphite oxide were showed in Fig. 2. The X-ray diffraction spectra of graphite showed that the diffraction peak was at 26.5°. The interplanar crystal spacing of graphite was 0.34nm by Bragg equation. The X-ray diffraction spectra of graphite oxide showed the peak of 26.5°was disappeared and the diffraction peak occurred at 10°, and the interplanar crystal spacing of graphite oxide was 0.94nm. The results accorded with the literature, and those proved that the graphite was completely oxidized.

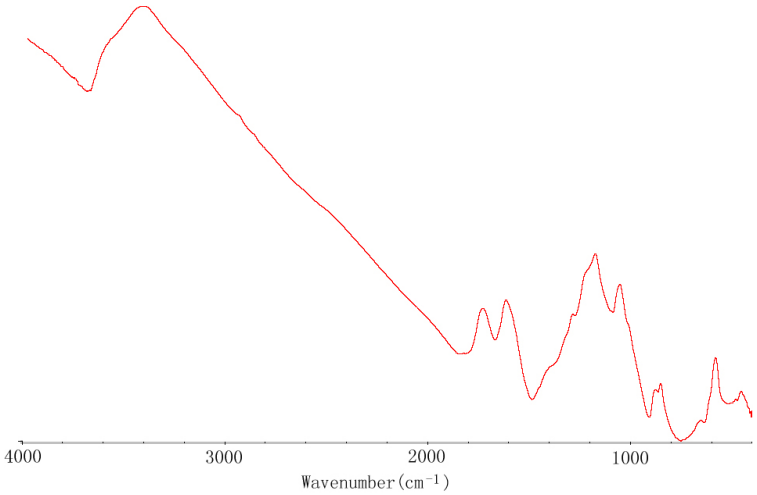

Fig. 1 The FTIR of the graphite oxide

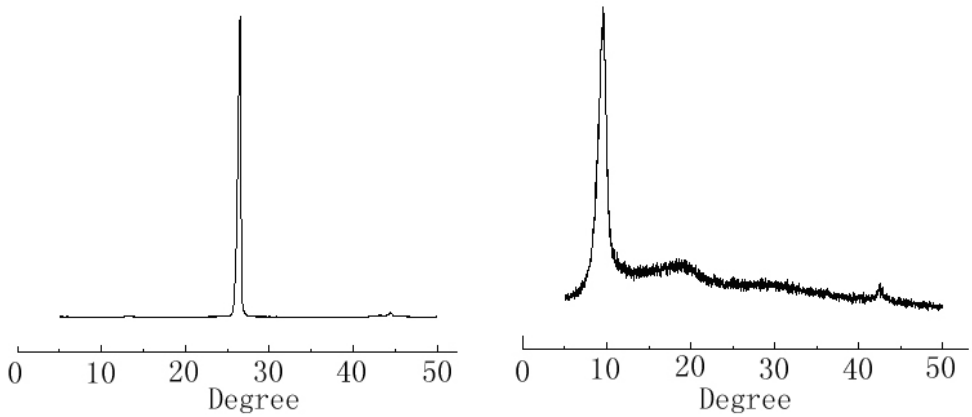

Fig. 2 The XRD of graphite and graphite oxide

The most important feature of two preparation methods of graphene oxide was the graphene oxide prepared by thermal expansion would lose large number of active functional groups, such as hydroxyl, carboxyl group, et al. The decrease of active functional groups in graphene oxide was disadvantage to chemical modification. However, it must choose the appropriate solvent to prepare graphene oxide by ultrasonic dispersion. The preparation of graphene oxide by ultrasonic dispersion indicated that the graphite oxide can be easily dispersed in water, N-methylpyrrolidone (NMP) and N,N-dimethyl-formamide (DMF), and dispersed solution stability was formed. But it was difficult to disperse in acetone and dimethylbenzene. The Raman spectra of graphene oxide were shown in fig. 3.

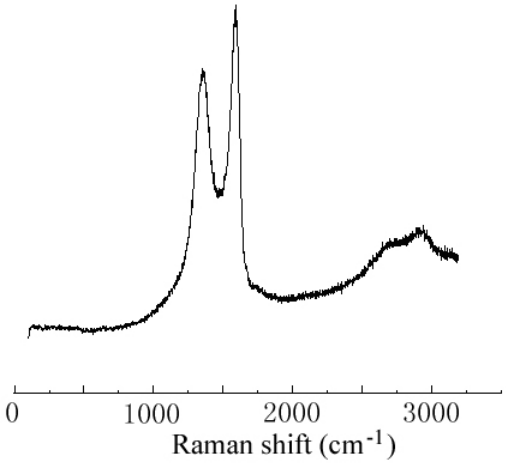

Fig. 3 The Raman spectra of graphene oxide

The graphene oxide prepared by ultrasonic dispersion and thermal expansion were characterized by XRD and SEM, and the measurement were shown in figure 4, figure 5, figure 6 and figure 7. The

structure of graphene oxide by two different preparation methods was significant difference. The diffraction peak of graphene oxide prepared by ultrasonic dispersion was 10°, but the diffraction peak of graphene oxide prepared by thermal expansion occurred at 20-30°. The SEM spectra indicated that the degree of separation was different. Generally, the degree of separation of graphene oxide prepared by ultrasonic dispersion was better than that of prepared by thermal expansion.

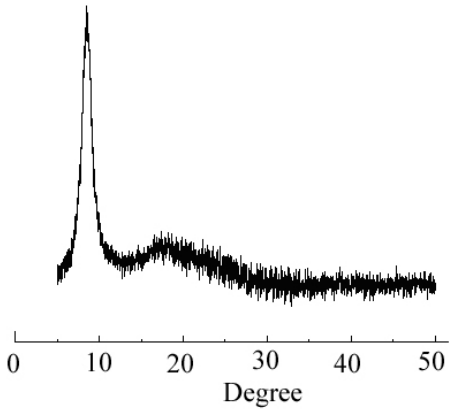

Figure 4 The XRD of graphene oxide prepared by ultrasonic dispersion

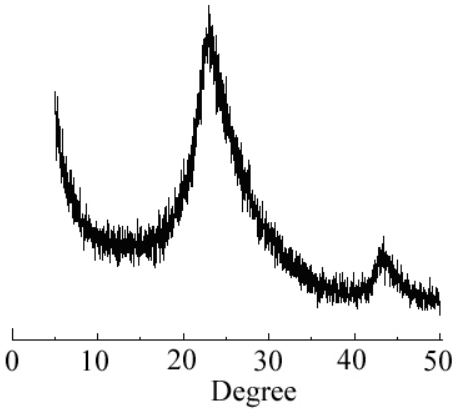

Figure 5 The XRD of graphene oxide prepared by thermal expansion

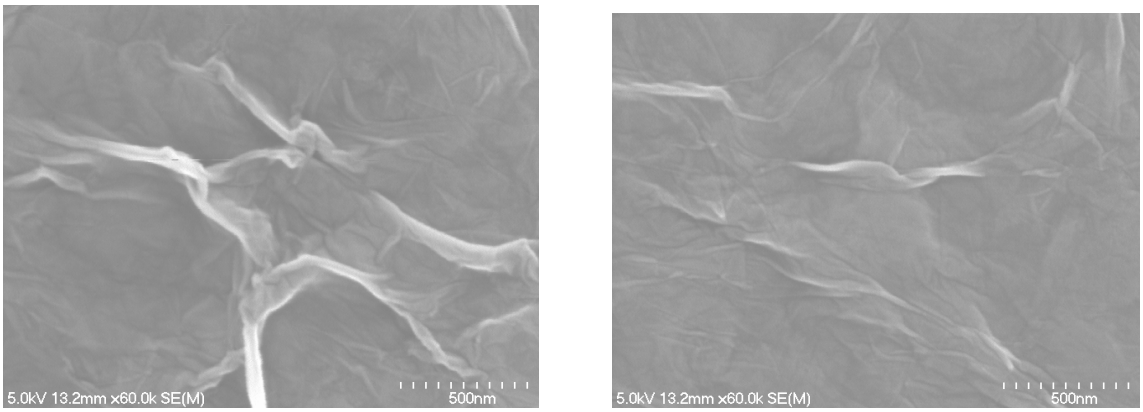

Figure 6 The SEM of graphene oxide prepared by ultrasonic dispersion

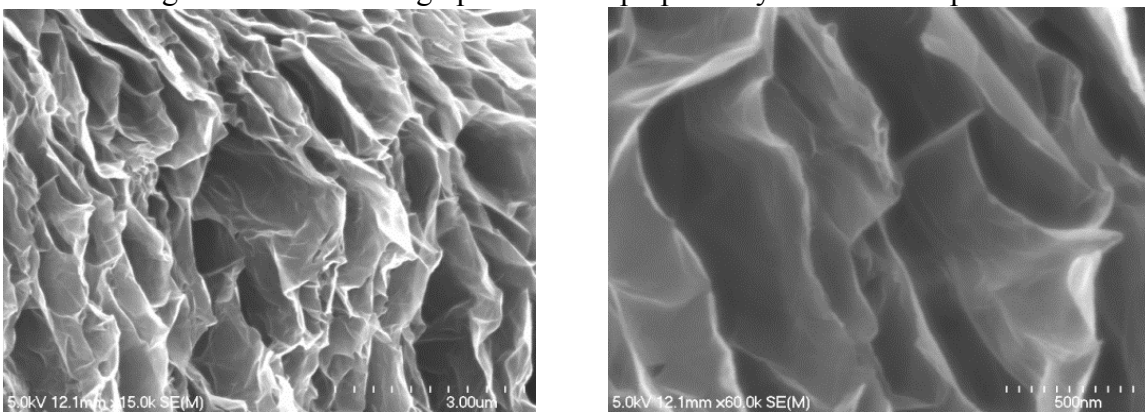

Figure 7 The SEM of graphene oxide prepared by thermal expansion

Conclusion

Some graphene oxides were prepared by thermal expansion, and other graphene oxides were prepared by ultrasonic dispersion in solvent, such as water, N-methylpyrrolidone (NMP), N,N-dimethyl-formamide (DMF), acetone, dimethylbenzene. The FTIR and XRD of the graphite oxide were measured, the results showed the graphite was completely oxidized. The Raman spectra, XRD and SEM of graphene oxides were tested. The results indicated that the structure of graphene oxides prepared by ultrasonic dispersion and thermal expansion was different. Those differences would

effect the chemical modification of graphene oxides. More work will do about the chemical modification of graphene oxides and the preparation of polymer/graphene nanocomposites.

Keywords: Raman Spectroscopy; Sr_2FeMoO_6

Abstract. The micro-Raman technique is used to examine the phase purity of Sr_2FeMoO_6 compound in this work. It is found that the Raman spectra of Sr_2FeMoO_6 compound without impurity consists of the peaks at about 440cm^{-1} and 620cm^{-1}. The broad peak and shoulder at 820-890cm^{-1} in the Raman spectra is assigned to the most common impurity $SrMoO_4$ and some other unidentified co-existing phases, which is approved by the results of X-ray diffraction.

Introduction

Double perovskite compound $A_2BB\acute{}O_6$ with A an alkaline earth and B, Ḃ two different transitional metals has been most studied since the discovery of large room-temperature low field magnetoresistance in Sr_2FeMoO_6 [1]. Crystal structure of Sr_2FeMoO_6 is known as cubic [2]or tetragonal [3] with the regular arrangement of the alternating FeO_6 and MoO_6 octahedra. Depending on the size of the A cations, the structure has been described as cubic (Ba_2FeMoO_6, crystal symmetry $Fm\bar{3}m$), tetragonal (Sr_2FeMoO_6, crystal symmetry $I4/m$) or monoclinic lattice (Ca_2FeMoO_6, crystal symmetry $P2_1/n$) [4, 5]. Band-structure calculations show that Sr_2FeMoO_6 is a half−metal [1], where the Mo t_{2g} spin-down sub-band (hybridized with the Fe t_{2g} spin-down sub-band) crosses the Fermi level, while the spin-up sub-band, essentially composed of Fe t_{2g} and Fe e_g states, is separated by an insulating gap.

For the potential application of Sr_2FeMoO_6 in spin devices, both large magnetoresistance and high Curie-temperature (T_C) are required. As reported in ref [6], the low-field magnetoresistance of Sr_2FeMoO_6 decreases linearly with the increasement of the concentration of anti-site defects (amount of Fe on Mo site or Mo on Fe site). Meanwhile, Park [7] and Aguilar [8] reported that anti-site defects could lower T_C of Sr_2FeMoO_6 to large degree. Therefore, anti-site defects bring large effects on the magnetic properties of Sr_2FeMoO_6. In order to obtain the Sr_2FeMoO_6 compound with higher degree of ordering (1-AS), researchers improves the preparation process of Sr_2FeMoO_6 little by little. Furthermore, doping method is also introduced to enhance the degree of ordering of Sr_2FeMoO_6 [9,10]. As a matter of fact, besides the factors mentioned above, purity of the compound is another important factor that affects on the degree of ordering. The lower the purity, the lower the degree of ordering. Generally, X ray diffraction is the most-common used method to detect the purity of the compound. Meanwhile the micro-Raman technique is also an useful method to analyze the phase of the ceramic compound. However, Raman spectra of Sr_2FeMoO_6 is rarely reported up to date. In this work, we synthesized Sr_2FeMoO_6 compound and detected the Raman spectra of the compound. It is found that the main Raman spectra of Sr_2FeMoO_6 consists of the peaks at about 420cm^{-1} and 620cm^{-1}, the spectra of the common impurity $SrMoO_4$ appears at about 840cm^{-1}.

Experimental

Polycrystalline Sr_2FeMoO_6 (SFMO) compounds were prepared by standard solid-state reaction. Stoichiometric powders of $SrCO_3$, MoO_3 and Fe_2O_3 were mixed, ground and fired at 900 ℃ for 5

hours in air. The pre-reacted mixture was then finely ground, pressed into pellets and sintered at 1280 ℃ in a stream of 5% H_2/Ar gas. The flow of the gas is controlled at 50mL/min and 30mL/min, the as-prepared compound is named as SFMO A and SFMO B.

Phase purity of the compounds was examined by X-ray diffraction (XRD) and micro-Raman technique. X-ray diffraction was carried out using a Bruker D8 Advance diffractometer with the 2θ range of 15˚-100˚. Raman spectra was measured on FTIR-7600 spectrometer with infrared emitter.

Results and discussion

Figure 1 (a) presents the XRD pattern of SFMO A compound. Evidently, SFMO A compound is of single phase without detectable impurity phases. The crystal symmetry is tetragonal lattice and the space group is I4/m. Owing to the ordering arrangement of Fe and Mo on B and B́ sites in perovskite structure, the superstructure reflection (101) at ~19˚is observed in our pattern. The Raman spectra of the phase-pure SFMO A compound was measured and the spectra is shown in Fig. 1(b). Two weak peaks are found at 440cm^{-1} and 620cm^{-1} respectivelly, and these two peaks should be assigned to Sr_2FeMoO_6 compound considering the nature of single phase of SFMO A compound. As reported by Son et al [11], the Raman spectra of Sr_2FeMoO_6 compound consists of the peaks and shoulders at about 770cm^{-1}, 620cm^{-1}, 440cm^{-1}, 390cm^{-1}, 290cm^{-1} and 210cm^{-1}, which is consistent with our results.

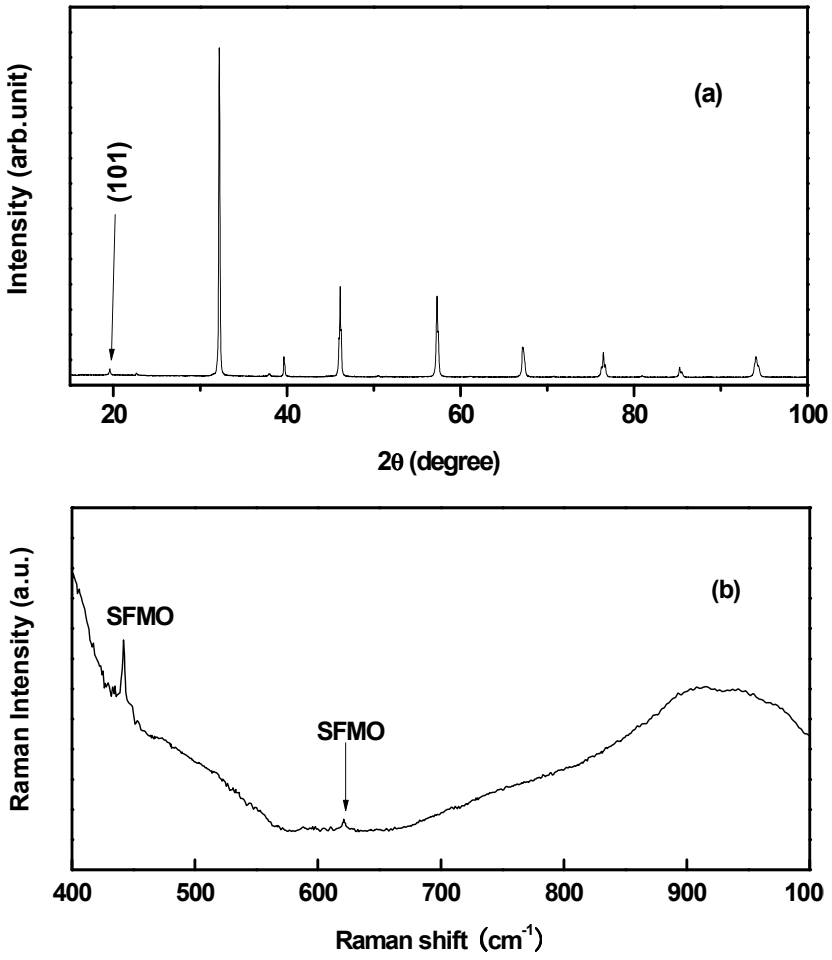

Figure 1 X-ray diffraction pattern (a) and Raman spectra (b) of SFMO A compound

Raman spectra of SFMO B compound is shown in Fig. 2(a). Different from the Raman spectra of SFMO A compound, another broad peak and shoulder at 820-890cm^{-1} are found besides the peaks at 440cm^{-1} and 620cm^{-1}. According to the results reported in ref [11], the peaks at 882.3cm^{-1}, 840.1cm^{-1} and 789cm^{-1} should be assigned to $SrMoO_4$, and other wide peaks and shoulders

probably due to $SrFeO_3$ and other unidentified co-existing phases. Therefore, the wide peak and shoulder observed in Fig. 2(a) maybe from $SrMoO_4$ and other unidentified co-existing phases. Consistent with the results of Raman spectra, besides the peaks from Sr_2FeMoO_6 double perovskite, the characteristic peak of $SrMoO_4$ at 27.5° is clearly observed in the XRD pattern of SFMO B compound (Fig. 2(b)).

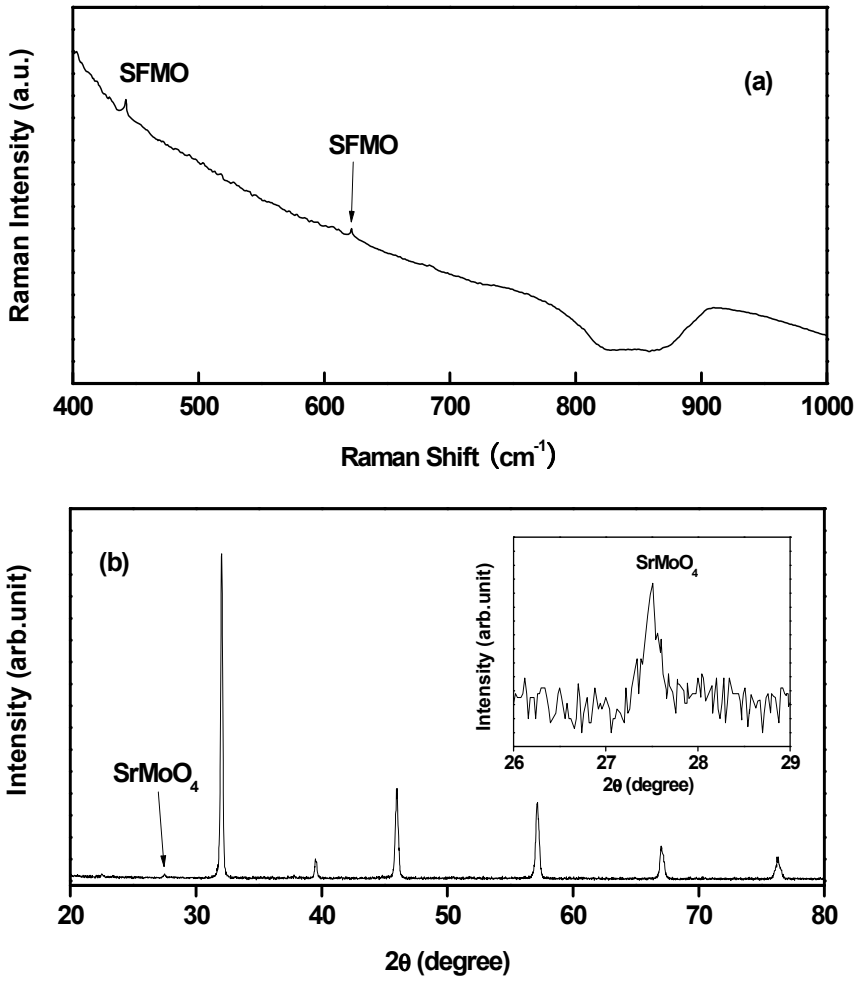

Figure 2 Raman spectra (a) and X-ray diffraction of SFMO B compound with impurity. Inset in (b) shows the enlarged pattern around 27°.

Conclusion

Both micro-Raman and X-ray diffraction technique are used to examine the phase of Sr_2FeMoO_6 compound. Consistent with the results of X-ray diffraction, the Raman spectra of phase-pure Sr_2FeMoO_6 consists of the peak at 440cm^{-1} and 620cm^{-1} with weak intensity. The Raman spectra of Sr_2FeMoO_6 compound with impurity is also examined in this work, it is found that another broad peak and shoulder at 820-890cm^{-1} is observed besides the peak at 440cm^{-1} and 620cm^{-1}, which is assigned to $SrMoO_4$ and other unidentified co-existing phases.

Key words: sucrose; solid sulfonic acid; β-amino ketone; Mannich; 2-Acetylpyrazine.

Abstract: Sucrose char sulfonic acid(SCSA) efficiently catalyzed the one-pot, three-component Mannich reaction of ketones, aromatic aldehydes and different amines in ethanol at 30℃ and afforded the corresponding β-amino carbonyl compounds in good to excellent yields . This method provides a novel and improved modification of the three-component Mannich reaction in terms of mild reaction conditions , clean reaction profiles and a simple workup procedure.

Introduction

The Mannich reaction is one of the most important fundamental carbon-carbon bond-forming reactions in organic chemistry for the preparation of secondary and tertiary amine derivatives [1]. The products of Mannich reaction are mainly β-amino carbonyl compounds and 1, 2-amino alcohol derivatives, which are valuable synthetic intermediates for the synthesis of drugs and biologically active compounds.[2] Though the study on Mannich reaction has developed over the past decades[3], the most straightforward and atom-economic route to β-amino carbonyl compounds is the direct three-component reaction[4] of aldehydes,amines and ketones. Solid sulfonic acid catalysts such as sulfonic acid resin,PS-SO_3H[5]and sulfonic groups functionalized silica materials[6]are always as an alternative for sulfuric acid. Recently,carbon-based solid acids,a novel and inexpensive solid acid with mild acidity,has emerged as a substituted for conventional acidic catalysts in different areas of organicsynthesis: esterification, hydrolysis, hydration,etc.[7] We reported the bamboo char sulfonic acid for acid catalyzed reaction of Claisen-Schmidt condensation between benzaldehyde and acetophenone[8].A series of biomass char sulfonic acid using saccharide molecules, bamboo sawdust,pine needles, etc. as raw materials have been prepared in our laboratory. High catalytic activity, low toxicity, moisture and air tolerance make biomass char sulfonic acid catalysts attractive.We report herein full details of a novel, convenient, and simple procedure to realize a one-pot three-component reaction of aldehydes,amines and ketones used sucrose char sulfonic acid as a green catalyst for the preparation of β-amino carbonyl compounds in ethanol.

Experimental

SCSA was prepared according to Xu Qiong's procedure[8]. The catalyst was separated in the first stage of the above work up procedure. The residue was washed with acetone and dried at 100℃ for 5 h to give pure SCSA for further runs.

A mixture of aromatic aldehyde, (2.0 mmol), amines (2.0 mmol), cyclohexanone (6.0 mmol) or 2-Acetylpyrazine. (2.0 mmol) and catalyst were stirred in anhydrous Ethanol (5 ml) at 30℃. After the reaction was completed, the mixture was cooled and then filtered to separate the solvent. The solid was washed twice with anhydrous ethanol and dissolved in CH_2Cl_2. Catalyst was removed by filtration., and filtrate was evaporated under vacuum condition. The crude product was purified via recrystallisation from anhydrous Ethanol to give the resulting product 4.

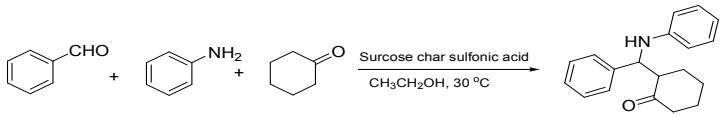
Results and discussion

Initially, the three-component Mannich reaction of benzaldehyde(2.0 mmol) , aniline(2.0 mmol) , and cyclohexanone(6.0 mmol) was examined(Scheme 1). Several solvents were screened in the model reaction. The results of extensive acid and solvent screening and optimization are shown in Table 1. Interestingly, the Mannich reaction showed an intriguing solvent effect, In ethanol gave a yield of 91%(entry 1) which was higher than that in CH3CN, ethyl acetate, CH2Cl2 . And we

pleasantly surprised found that Mannich reaction with solvent-free and in water gave the yield which was slightly lower than in Ethanol (entres 6, 10) .

We also screened different common sulfonic groups catalysts for their ability to catalyzed the three-component Mannich type reaction. The amount of catalysts used equaled acid capacity of SCSA. Results are depicted in Table 1(entries 1-5). It is clearly that the yield of Mannich base in the presence of sucrose char sulfonic acid is higher than that of either typical acid catalyst, This novel catalyst are high activity, simplicity of preparation method, low cost, wide availability of raw materials which can be a benefit for its extensive application in organic synthesis reactions.

Table 1 Influence of catalysts and solvent on the Mannich reaction of aromatic aldehydes, aromatic amines and cyclohexanone [a]



entry	catalyst	solvent	**I**solated yield/%

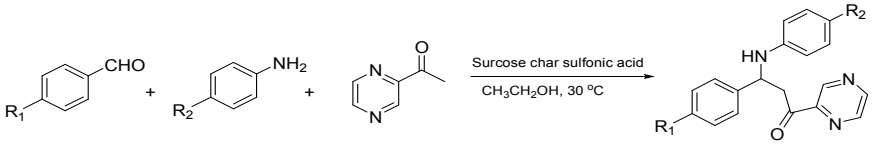
9	SCSA	CH_3CN	56
10	SCSA	water	79

[a] Benzaldehyde(2.0 mmol) , aniline(2.0 mmol) , and cyclohexanone(6.0 mmol), 4% mol catalyst, r.t. 6 h

Encouraged by the remarkable results obtained with the above reaction conditions, and in order to show the generality and scope of this new protocol. We further surveyed the scope of arylaldehydes and amines in the direct Mannich reactions in the presence of 8 mol % SCSA as the catalyst and the results were summarized in Table 2. Table 2 clearly demonstrates that SCSA are excellent catalysts for Mannich reactions in ethanol. Thus, a variety of aromatic aldehydes and amines, including electron-withdrawing and electron-donating groups, were tested using our new method in ethanol in the presence of SCSA. In Table 2, it seemed that there was no remarkable electronic effect from the substituents at aldehyde moiety, since aryladehydes with both electron-donating groups like $-OCH_3$ (Table 2, entries 5-8,) and electron-withdrawing groups like $-NO_2$ (Table 2, entries 9-12) could be applied as efficient candidates for the direct Mannich reaction at 30℃ to offer the expected β-amino carbonyl compounds good yields. The scope of our method was extended to other amines. In the case of amines having an electron-donating group, such as 4-methylaniline(entry 2), the corresponding β-amino carbonyl compounds were obtained good yields. Furthermore, amines with electron-withdrawing groups, such as 4-nitrylaniline(entry 4) gave the desired product in low yield.

Table 2 One-pot three-component Mannich reaction of aromatic aldehydes, aromatic amines and 2-Acetylpyrazine in sucrose char sulfonic acid catalytic system



entry	R_1	R_2	Isolated yield/%
1	-H	-H	67
2	-H	- CH_3	73
3	-H	- Cl	59
4	-H	- NO_2	45
5	-OCH_3	-H	55
6	- OCH_3	- CH_3	74
7	- OCH_3	- Cl	48
8	- OCH_3	- NO_2	33
9	-NO_2	-H	69
10	- NO_2	- CH3	67
11	- NO_2	- Cl	57
12	- NO_2	- NO_2	66

Reaction conditions : aldehyde (2.0mmol), amine (2.0 mmol), 2-acetylpyrazine (2.0 mmol), catalyst(4 mol %), CH_3CH_2OH (3 ml), 30 ^oC

Finally, the recycling performance of SCSA was investigated using the three-component Mannich reaction of benzaldehyde, aniline and cyclohexanone. The yields of Mannich base were 91%, 88 %, 87%and 86%. respectively, which showed good reusability of this catalyst. The weight of catalyst increased slightly and no sulfate ion was detected in reaction mixture after each reaction which indicated that reactants or products may deposit in catalyst . Compared with the traditional solvents and catalysts, the easy recycling performance is also an attractive property of the SCSA for the environmental protection and economic reasons.

Conclusion

In summary, we herein described an originally and effectively SCSA catalyzed protocol for the construction of β-amino ketones via three-component direct Mannich reaction. The merit of this methodology is simple, mild, efficient and the raw materials are cheap . Therefore, we believe that the work reported here would have potential application in green chemistry.

email: weina31@126.com

Keywords: Peracetic acid, sewage sludge, pretreatment, biomass material

Abstract: Sewage sludge is difficult to degrade in anaerobic digestion systems and pretreatments have been shown to speed up the hydrolysis stage. In this paper sludge anaerobic digestion experiments with peracetic acid as a pretreatment were carried out and the effects of acid pretreatment using peracetic acid on subsequent digestion were investigated. It has been proved that this treatment effectively leads to a solubilisation of organic material and thus leads to a increase of soluble chemical oxygen demand(SCOD) and volatile fatty acids(VFA)concentration. Besides, the SV of sludge was reduced and the settling characteristics of sludge were improved. But high dosage of peracetic acid lead to a decrease in biogas production and the proper dosage was 20 g/kg DS. It can be concluded that sludge anaerobic digestion with peracetic acid pretreatment is an effective method for biomass material transformation.

Introduction

Sewage sludge is the main waste from the urban wastewater treatment process and the amounts of this residue are increasing in many parts of the world[1]. So far, sewage sludge has been disposed off by some methods, such as soil application [2][3], anaerobic digestion[4] and landfilling [5]. As one kind of biomass materials, sludge anaerobic digestion produces biogas and reduces the amount of organic matter. Treatment of sewage sludge via anaerobic digestion has been carried out widely and technology has recently received increased interest in many countries due to the renewable energy it can produce.

However, anaerobic digestion has some limitations, such as the length of time it takes for the sludge to be digested and the ineffectiveness of totally breaking down the solids. Various pretreatment technologies have been suggested in the literature as solutions for overcoming these limitations and for improving the biogas production rate [6-8]. Methods that were previously studied include chemical, mechanical and thermal treatments [9-10]. In the past, several oxidants have been applied to break down sewage sludge, although only few have been combined with anaerobic digestion [11]. Peracetic acid is an useful oxidant and it has many applications in the medical and food industry as a disinfectant and in water purification as an oxidizing agent. The main advantage is that no toxic degradation products are formed.

In this paper, the effect of peracetic acid on anaerobic digestion of sewage sludge was studied. The objectives of this research were finding out the function of peracetic acid pretreatment on anaerobic digestion of sewage sludge and bio-hydrogen production. Besides, the settling characteristics of sludge were also examined.

Materials and Methods

Sludge sample:The sewage sludge used was collected from the Wastewater Treatment Plant of Hanxi, Wuhan city and stored at 4℃ before use. The main characteristics of sludge are listed in Table 1.

For the treatment, a 1L sludge sample was introduced in a breaker, and an appropriate amount of peracetic acid was added. A dose range between 10 and 60g peracetic acid /kg dry solids(DS) was applied to the sludge. The sludge was gently stirred by a magnetic stirrer during the reaction. A

Table 1. Main characteristics of the sewage sludge.

Moisture %	Total solid(TS) mg/L	PH	Organic matter %
98.5	20200	7.07	79.5

release of soluble chemical oxygen demand (SCOD) due to this stirring was not expected because of its gentle nature.

Compositional analysis: The following components were analysed before and after pretreatment: SCOD, and concentration of volatile fatty acids(VFA). SCOD and DO were analyzed using a HACH DR/2000 spectrometer(Hach Company, USA). VFA concentrations were analyzed by a High Performance Liquid chromatograph(GP40, Dionex, CA) with an absorbance detector(AD20, Dionex) and a 300 mm-7.8mm Metacarb 67H column(Varian, CA) using 0.05 M H2SO4 as mobile phase.

The settling characteristics of sludge: Settling velocity(SV) is one of sludge's most important settling parameters in routine process control. SV was calculated as the volume ratio of concentrated sludge to the initial sample after 30min settlement in a 100ml measuring cylinder.

Results and Discussions

Variation of SCOD and VFA concentration： Fig. 1 shows the effect of the peracetic acid treatment on the SCOD concentration in the sludge. As organic matter in the sludge was degraded during the treatment, with the increase of peracetic acid dosage, a obvious increase of SCOD was noticed. However, for the dosage of 40 and 60g/kg DS, the concentration of SCOD decreased after 3h treatment. This may be attribute to the oxidation reaction between the liquid organic matter in sludge and incompletely reacted peracetic acid. It can be concluded that high concentration of peracetic acid is not needed and it may even affect the methane yield in anaerobic digestion as the decrease of SCOD in sludge. In this experiment, the economic dosage of peracetic acid was 20g peracetic acid/kg DS. After 12h treatment, the VFA concentration of sludge in the dosage of peracetic acid of 10g/kg DS, 20g/kg DS, 40g/kg DS, 60g/kg DS was 675mg/L, 993mg/L, 4653 mg/L and 8910mg/L. The large increase in VFA concentration is due to the partial oxidation of organic matter to VFAs. It appears that the oxidative strength of the treatment is sufficient to result in an effective oxidation. Besides, the large increase in VFA concentration is also due to the addition of peracetic acid mixture.

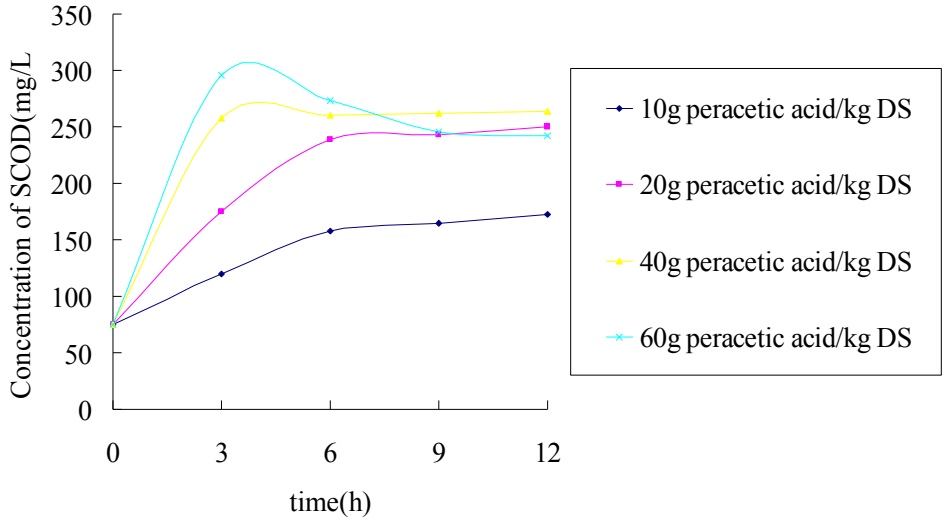

Fig. 1 SCOD of treated sludge as a function of time

Methane yield in anaerobic digestion： Fig.2 shows the biogas production (in mL/L) at the dosage of 20g/kg DS as a function of time. Methane production, the major result of anaerobic

digestion, was markedly increased. However, applying high dosage even leads to a significant lower biogas produciton. Although higher concentrations leads to a high sludge sulubilisation and hence a large availability of highly biodegradable organic matter, these soluble organics are not further converted into extra biogas. Thus, high dosage of peracetic acid was not needed for sludge anaerobic digestion.

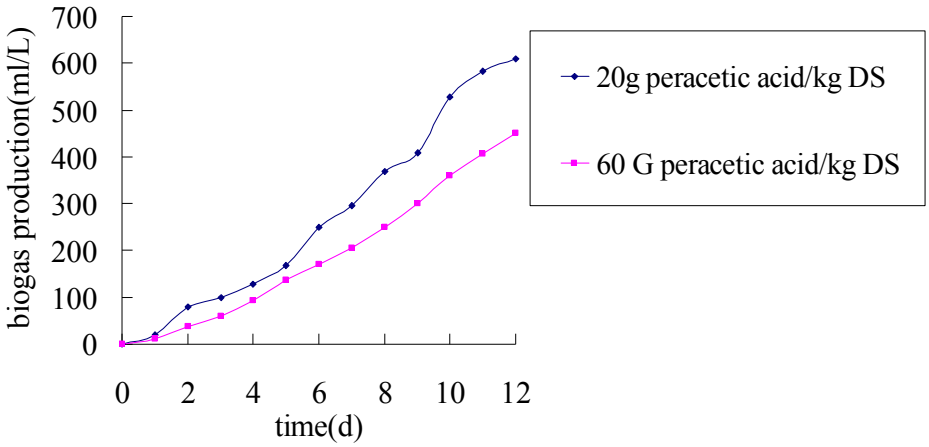

Fig.2 Biogas production of sludge as a function of time

Effect of ultrasonic pretreatment on sludge settling characteristics： In order to evaluate effect of the ultrasonic pretreatment on sludge settling characteristics, one parameters of sludge, namely, SV was studied. Fig.3 shows the trend of changes of SV of treated(with the dosage of 20g/kg DS) and untreated slduge. According to this graph, sludge using ultrasonic waves reduces SV and therefore, improves the settling characteristics of the sludge.

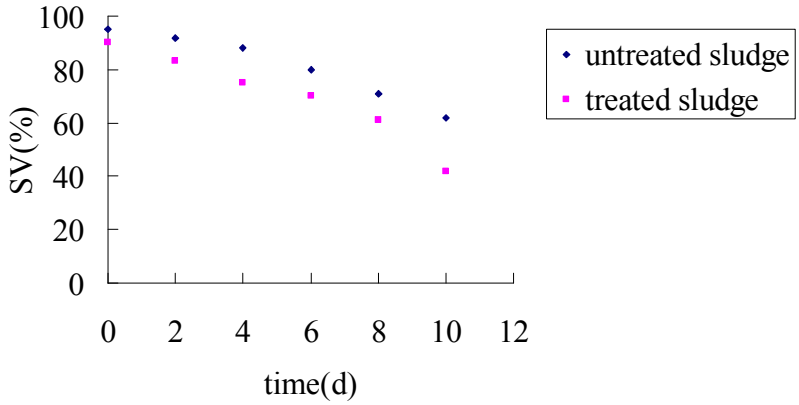

Fig. 3 SV of treated and untreated sludge as a function of time

Conclusions

1. The pretreatment of sludge by peracetic acid has a significant effect on the sludge biodegradability during the anaerobic digestion that increases the SCOD and VFA concentration as well as biogas generation.

2. The settling characteristics of sludge was also improved.

3.The higher dosage of peracetic acid may lead to lower biogass production and a proper dosage was 20g/kg DS.

Keywords: multiblock copolymers; sulfonated poly (arylene ether sulfone); oligomers

Abstract. A series of multiblock copolymers based on sulfonated poly (arylene ether sulfone) (bSPAES-SF) with highly rigid hydrophilic sulfonate blocks and flexible hydrophobic blocks were successfully synthesized by the condensation of sulfonated decafluorobiphenyl-terminated oligomers and the hydroxyl-terminated oligomers. The former oligomers were sulfonated by fuming sulfonic acid. The bSPAES-SF membranes with IEC of 1.26-1.70 mmol/g exhibited high proton conductivity, hydrolytic and dimensional stability.

Introduction

In recent years, polymer electrolyte membrane fuel cells (PEMFCs) have drawn considerable attention as clean energy sources for portable devices, stationary power sources and hydrogen energy vehicles due to the high energy efficiency and environmental friendliness.[1] Polymer electrolyte membrane (PEM) is one of the key component of PEMFC system, which conducts protons from anode to cathode and avoids fuel and oxidizing agent from mixing.

Sulfonated aromatic hydrocarbon polymers as alternative materials have been intensively studied in the past decades.[2] However, most of the developed hydrocarbon-based PEMs suffer from dilemma of the basic properties for PEMs of ion exchange capacity (IEC), water uptake and proton conductivity. Recently, there are a handful of reports on the hydrocarbon polymers with high locally concentrated sulfonic acid groups. The as-prepared PEMs showed enhanced nano-scale phase-separation morphology and improved proton conductivity at moderate IEC levels which was a great advantage in PEMFCs application.[3]

In this report, we prepared a series of PEMs derived from multiblock copolymers of sulfonated poly (arylene ether sulfone) (bSPAES-SF) with highly sulfonated hydrophilic blocks simply sulfonated by fuming sulfonic acid. Their characterizations, fundamental physical properties and hydrolytic stability were investigated.

Experimental

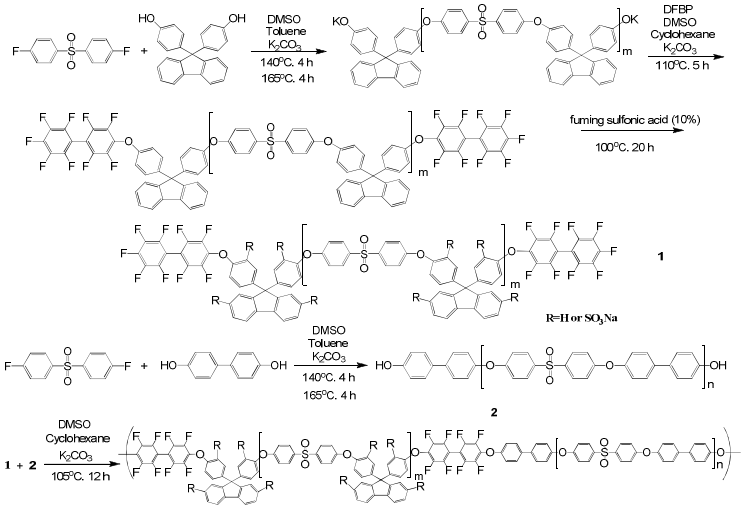
4,4'-Difluorodiphenyl sulfone (DFDPS), 4,4'-biphenol (BP), 9,9-bis(4-hydroxyphenyl) fluorene (BHPF) were recrystallized from toluene, acetone and ethanol-water mixture before use, respectively. Dimethyl sulfoxide (DMSO) was dried over CaH_2 and distilled under reduced pressure and stored over 5 Å molecular sieve, while toluene and cyclohexane were dried over P_2O_5 and stored over sodium prior to use. Potassium carbonate was dried at 120^{o}C for 6 h under vacuum before use. Fuming sulfuric acid (SO_3, 20%) and other reagents were used as received.

The synthetic route of the multiblock copolymers was illustrated in Scheme 1. The copolymers were named as bSPAES-SF(m/n), where m and n refer to the block length of the hydrophilic and hydrophobic blocks, respectively. The hydrophobic, DFBP-terminated hydrophilic blocks (or oligomers) and the final multiblock copolymers were synthesized by the nucleophilic substitution reaction. The DFBP-terminated oligomers were sulfonated by fuming sulfuric acid (10%) at 100 ^{o}C for 20 hrs and purified by salting out method. The bSPAES-SF membranes (about 50 μm) were prepared by solvent casting method in DMSO solution and proton exchanged with 2 M HCl.

^{1}H NMR, reduced viscosity (η_r) , mechanical tensile tests, SEM, Water uptake (WU), the dimensional change, IEC, proton conductivity (σ) and hydrolytic stability were measured according to the method described elsewhere [4].

Results and discussion

The synthetic route for oligomers and multiblock copolymers is shown in Scheme 1. Post sulfonation method has been used to prepare hydrocarbon PEMs, but the inevitable polymer degradation could cause deterioration of mechanical strength of the as-obtained membranes.[5] To avoid this, the sulfonation of oligomers was carried out instead of the copolymers. Sakaguchi et al. studied the sulfonation of fluorine-containing poly(arylene ether ketone) copolymers by using concentrated sulfuric acid as the sulfonating reagent.[6] In this case, the sulfonation reaction was conducted by using fuming sulfuric acid as the sulfonating reagent and carried out at 100°C through electrophilic substitution reaction. Figure 1 shows the ^{1}H NMR spectra of the hydrophilic oligomers after the sulfonation reaction. It indicated that the substitution reaction occurred on the positions of fluorene moieties, both the pendant and backbone phenyl rings due to the relatively higher electron density as reported by [3]. For the hydrophobic oligomers, the block length (5, 10 and 15) was controlled by varying the molar ratio of starting materials of DFDPS and BP. The reduced viscosities of the copolymers were in the range of 1.1-1.5 dL/g, indicating the rather high molecular weight of the copolymer products. Transparent, tough and flexible membranes were successfully obtained through solvent-casting method.



Scheme 1. Synthetic route of bSPAES-SF copolymers.

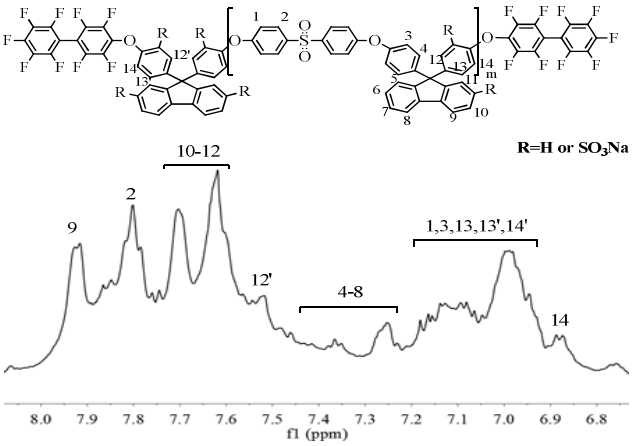


Figure 1. ^{1}H NMR spectra of sulfonated oligomers (m=5).

Figure 2 shows the SEM images of bSPAES-SF(5/10). Smooth and uniform surface and fracture surface were observed for the membranes, indicating their homogenous morphology in the micrometer scale.

Table 1 summarized the physical properties of the obtained bSPAES-SF membranes. IEC is an important property parameter for the PEMs because it is the indicator of the ionic group content inside the membrane matrix and closely related to the absorbed water, membrane swelling and proton conduction. As shown in Table 1, the titration IECs of the obtained bSPAES-SF membranes were 1.12, 1.26 and 1.70 mmol/g.

Obviously, the water uptakes are closely related to the IEC values and temperature as

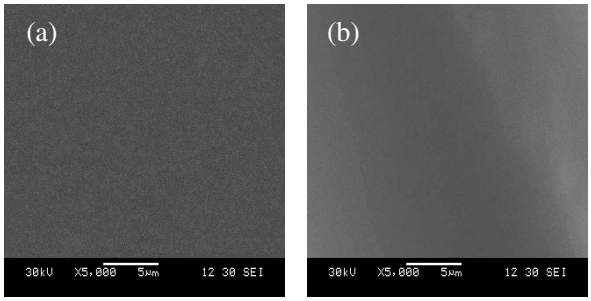

Figure 2. SEM micrographs of multiblock membranes (a) bSPAES-SF (5/10) in plane direction. (b) bSPAES-SF (5/10) in section direction.

reported [8]. For example, the membrane of bSPAES-SF(5/5) displayed 2.2-2.3 times water uptakes of that for bSPAES-SF(5/15). Based on the comparison of the average water molecules absorbed per sulfonic acid group, λ, it is also found that the λ value also increased with the IEC, it was about 25% larger for bSPAES-SF(5/5) than that for bSPAES-SF(5/10) and 60% larger than that for bSPAES-SF(5/15). Considering the same hydrophilic and hydrophobic block structures, the difference in λ could be caused by the different block length of hydrophobic blocks. For the hydrophobic blocks with larger block length, the enhanced hydrophobic nature can weaken the water affinity of the membrane matrix, resulting in the reduced water absorbing capacity.

Table 1. Physical properties of the prepared bSPAES-SF membranes

Copolymer	η_r	IEC[a]	*WU*/%		λ^b	Δl_c/%		Δt_c/%		Y_M	E_B	*WL*	Tough-ness
	/dLg^{-1}	/mmolg^{-1}	30°C	80°C		30°C	80°C	30°C	80°C	/GPa	/%	/%	
bSPAES-SF(5/5)	1.5	1.7	48	72	16	8.4	14.4	17.5	24.9	\[c]	\[c]	1	V
bSPAES-SF(5/10)	1.1	1.26	28	37	12	3.2	7.0	10.2	16.1	0.9	23	0.4	V
bSPAES-SF(5/15)	1.2	1.12	21	31	10	2.7	5.1	4.6	11.6	1.1	29	0.6	V
Nafion 112	1.2	0.89	33	42	20	12	12	13	15	0.2	410	\	\

[a] Titration value; [b] at 30 °C; [c] not measured.

The through-plane and in-plane dimensional change was listed in Table 1. All the bSPAES-SF membranes exhibited obvious anisotropic swelling behavior in water with about one time larger through-plane dimensional changes than the in-plane ones. The preferable alignment of polymer chains in the plane direction due to the existence of rigid and bulky fluorenyl moieties in the polymer backbone could be responsible for it as reported.[3] In addition, in the in-plane direction, the dimensional changes (2.7-8.4%) were much smaller or slightly larger (for bSPAES-SF(5/5)) than Nafion 112 (12.0%) at 80oC although they had higher IECs, indicating their good dimensional stability. This will be favorable for the long term stability of the membrane-electrode-membrane assembly under changing operating conditions.

Table 1 lists the Young's modulus(YM), elongation at break point(EB), weight loss and toughness of the membrane after the hydrolytic test of the obtained bSPAES-SF membranes. During the test, the bSPAES-SF(5/5) was too brittle to be measured at dry state although the copolymer showed relatively higher η_r value (1.5 dL/g) than the other two copolymers. On the other hand, for the membranes of bSPAES-SF(5/10) and bSPAES-SF(5/15), they displayed Young's modula about 0.9-1.1 GPa and elongation at break point of 23-29%, suggesting the quite good mechanical strength. A slightly improvement in the mechanical strength with the increase in the block length of hydrophobic block was observed. It suggested that the appropriate structural design of the hydrophobic block are important to get tough and flexible membranes.

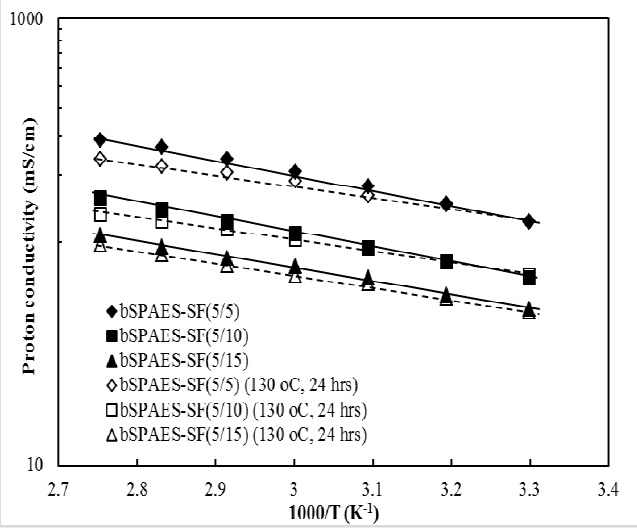

Figure 3. Temperature dependence of proton conductivity for the obtained bSPAES-SF membranes.

Proton conductivity is one of the most important property parameters to evaluate membrane performance. Figure 3 shows the temperature dependence of the proton conductivity for the obtained bSPAES-SF membranes in water. Membrane with higher IEC exhibited higher proton conductivities. For example, the membrane of bSPAES-SF(5/5) exhibited proton conductivity of 153 mS/cm at 30°C, and reached the maximum of 286 mS/cm at 90°C. Clearly, all the membranes showed Arrhenius-type temperature dependant proton conductivity behavior. According to

Arrhenius equation, the calculated activation energy of the obtained bSPAES-SF membranes were in the range of 11.50-12.76 kJ/mol, which is a little higher than the reported value of Nafion 117 (9.57 kJ/mol).[9]

The hydrolytic stability was simply evaluated by treating membrane samples in pressurized water at 130^{o}C for 24 hrs. After the treatment, all the bSPAES-SF membranes maintained original shape and could be bent and folded back without fracture, even for the membrane of bSPAES-SF(5/5) which is fragile at dry state. Weight losses no more than 1.0% were found for the obtained membranes, indicating the good integrity of the membranes under harsh conditions. From Figure 3, it is clearly noted that after the treatment, the membranes still kept high proton conductivities. For example, the membrane of bSPAES-SF(5/5) exhibited proton conductivity of 177 mS/cm and 162 mS/cm before and after the treatment at 50^{o}C.

Conclusions

A series of novel PEMs based on sulfonated poly(arylene ether sulfone) multiblock copolymers with high local ionic group concentration were successfully prepared from hydrophobic and post-sulfonated hydrophilic oligomers. The sulfonation reaction of the oligomers were carried out smoothly by fuming sulfonic acid at 100^{o}C. The obtained bSPAES-SF membranes (1.12-1.70 mmol/g) were ductile, exhibited moderate water uptakes, high proton conductivity, good dimensional and hydrolytic stability.

Keywords: Infrared Absorption Method; Detection; Carbon; Sulfur

Abstract. This paper focuses on discussing the principle of detecting carbon and sulphur by using infrared absorption method, characteristics of high-frequency heating, system blank value, and method for detecting trace carbon and sulphur.

Introduction

Chemical composition analysis of metal materials is an important way of evaluating the quality of materials, and currently, the composition of metal materials is measured by practical methods such as standard method and routine analysis method. When applying above methods, analysts often meet some difficulties and it is necessary to understand some principles. This paper focuses on discussing the principle of detecting carbon and sulphur by using infrared absorption method, characteristics of high-frequency heating, system blank value, and method for detecting trace carbon and sulphur.

Principles

Special analyzer integrated with gas absorption pool and high temperature furnace (usually using high frequency induction furnace) is a device specially used for detecting carbon and sulphur contents in steel and non-metallic materials by using infrared spectral absorption method. After heating and melting in high temperature, carbon (or sulfur) in the samples oxidizes in oxygen to generate CO_2 or SO_2. The contents of carbon/sulfur can be detected by using infrared absorption method.

Put the sample and fluxing agent into the porcelain crucible. When the sample is fused in the oxygen flow with high frequency induction heating, the carbon is oxidized into CO_2 and the sulphur is oxidized into SO_2, both of which are sent into the infrared analyzer. Since CO_2 and SO_2 can absorb specific wavelength of infrared, which leads to attenuation of infrared intensity, there is a function relationship between the attenuation of infrared intensity and the change of concentration of CO_2 and SO_2. The contents of carbon and sulphur can thus be measured according to the changes of the infrared intensity.

See Figure 1 for process diagram of carbon sulfur analyzer by using high frequency induction heating—infrared absorption method

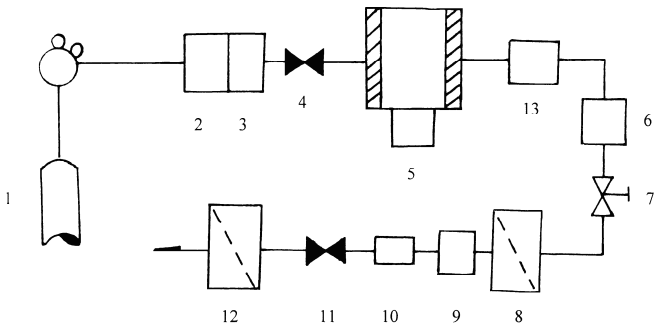

Figure 1 Process diagram of carbon sulfur analyzer by using high frequency induction heating—infrared absorption method

In the Figure 1: 1—Oxygen; 2—Soda asbestos; 3,6—Anhydrous magnesium perchlorate; 4,11—Flow controller; 5—High frequency induction heating furnace; 7—Flow control valve; 8—SO_2 infrared detector; 9—CO, SO_2 catalytic converter; 10—SO_3 absorber; 12—CO_2 infrared detector; 13—Filter.

Characteristics of high frequency heating

Principles

According to the Faraday's law of induction, when current passes a metal conductor in a high frequency alternating electric field, the metal conductor surface will generate powerful induced current. According to Joule-Lenz's law, alternating magnetic field will make the current in a conductor to flow through the surface of the conductor, causing skin effect. Instantaneous electric current density is proportional to the frequency. The higher the frequency is, the higher the intensity of the induced current will be concentrated in the surface of the conductor, namely, more serious skin effect. Reduction of effective conductive surface increases the resistance, which leads to rapid increase of the temperature of the sample metal conductor. As a result, the metal samples under oxygen-enriched state burns rapidly.

Advantages

We all know that, to detect the carbon and sulphur contents in steel by using combustion method, we must firstly make a complete combustion of the sample; especially when detecting sulfur, the detection is achieved through the detection of SO_2. Therefore, after combustion, it is better to generate more SO_2 but less SO_3 as far as possible, which is mainly determined by the heating temperature. Theoretically, proportion of SO_3 generation is higher than 15% when the temperature is lower than 1300℃; while when the temperature is higher than 1500℃, the ratio of SO_3 generation will be lower than 3%. The temperature of high frequency combustion method can reach 1400-1600℃.

Hence, the detection of carbon and sulphur by using Infrared Absorption is usually conducted by connecting with high frequency induction combustion method, so as to meet requirements of fast and accurate detection.

Detection of trace carbon and sulfur

Important Notice

Trace sulfur and carbon detection refers to the detection of $\mu g.g^{-1}$ level carbon and sulfur contents. Attention must be paid to the following aspects: ①stabilize and reduce system blank values: ②accurately measure blank values: ③Calibrate equipment; ④prepare the analysis of samples.

System blank value and its processing

When detecting ultra-low carbon/sulfur contents by using infrared spectral absorption method, there are trace carbon and sulfur elements in crucible, fluxing agent, and oxygen, which may affect the background of analyzing low content carbon and sulfur samples. All of these impacts are called system blank value.

The processing method is described as follows:

① Crucible: During making, sintering, packing and shipping processes, residuals of carbonate, sulfate, organic matters and moistures may remain stay on the surface. Thus the combustion process may generate CO_2, SO_2 and moisture. CO_2 and SO_2 entering into absorption pool may lead to the analysis results of carbon and sulphur contents higher than the actual contents; the moisture discharged during the combustion process may be condensed in the cold gas pipelines, and the moisture may cause CO_2, SO_2 or SO_3 to generate carbonic acid, sulphurous acid, sulfuric acid, which are adsorbed in the gas pipeline and thus cause the analysis results lower than the actual value. In addition, if moisture enters into absorption pool along with the gas to be analyzed, it may lead to detection result higher than actual value due to the similar infrared absorption wavelength between the gas and the SO_2. In summary, above reasons may affect the accuracy of carbon and sulfur analysis result. According to the provisions of international standard of ISO9556[1] and ISO4935[2], before use, crucible should be place in the high temperature furnace for burning with no less than 2h under the temperature of 1100℃ with the gas and oxygen flow. And then it is placed into a dryer for cooling and for future use. The time of storage in the dryer should be no more than 72h. When detecting low content carbon and sulfur, the crucible should be burned in oxygen flow under the temperature of 1350℃. If there is no available special crucible burning furnace, or if a temporary detection of low carbon and low sulfur samples is required, the same amount fluxing agent with samples to be measured can be put into crucible, and they are burned in high frequency furnace. Immediately after cooling down, they can be used for sample detection. This type of crucible is also called bottomed crucible, and the blank value obtained from this type of crucible is more stable than previous one. The experimental result shows that, the blank value after burning of crucible is significantly reduced. (See table 1)

Table 1. Blank values of crucibles with different crucible processing methods

Crucible processing methods	Weight of Tungsten granular (g)	Value input into PC (g)	Measured value of carbon (w/%)	Measured value of sulphur (w/%)
Unburned crucible	1.50	1.50	0. 014 8 0. 013 7 0. 012 3	0. 000 08 0. 000 10 0. 000 09
Burned crucible under the temperature of 1300℃	1.50	1.50	0. 000 41 0. 000 37 0. 000 39	0. 000 00 0. 000 01 0. 000 01
Bottomed crucible	1.50	1.50	0. 000 40 0. 000 36 0. 000 39	0. 000 01 0. 000 00 0. 000 01

②fluxing agent: Pure tungsten granular is used as fluxing agent during the detection of trace carbon and sulfur contents [3]. Before use, the adsorbed impurities (e.g., CO_2, SO_2, H_2O) should be removed. Tungsten granular can be firstly placed into drying oven and heated to the temperature 300℃ for 1h. After drying, it is taken out and put into a dryer for cooling. Then it is put into a grinding mouth bottle for future use. A good habit of timely sealing the cover of the tungsten granular container after taking out of tungsten granular shall be established. When analyzing, the volume of fluxing agent should be maintained constant, so as to eliminate the impact of unstable blank values caused by the different volume of fluxing agent. If using other fluxing agents or mixed fluxing agents, the volume of each time should be maintained constant. The experimental result shows that, the blank value of tungsten granular after drying is significantly reduced. (See table 2)

Table 2. Blank values of tungsten granular after different processing methods

Crucible processing methods	Weight of Tungsten granular (g)	Value input into PC (g)	Measured value of carbon (w/%)	Measured value of sulphur (w/%)
Unbaked tungsten granular	1. 50	1. 50	0. 000 77 0. 000 75 0. 000 83	0. 000 02 0. 000 01 0. 000 02
Baked tungsten granular under 300℃	1. 50	1. 50	0. 000 33 0. 000 30 0. 000 31	0. 000 01 0. 000 00 0. 000 00

③Oxygen: According to the stipulation of international standards of ISO9556[1] and 1SO4935[2], the oxygen purity should be at least 99. 5%, but the oxygen used for trace carbon and sulfur detection is high purity oxygen, with the purity of 99. 99%. The oxygen could be purified by using purification device before it enters into the analyzer. The purification devices of various models of Infrared carbon sulfur analyzer could be divided into two types: absorption, and heating-decomposition-absorption. Absorption makes use of the nature of CO_2 and SO_2, Namely, both two types of gases are acidic oxides, which can react with alkali as follows:

$$CO_2 + 2NaOH = Na_2CO_3 + H_2O$$

$$SO_2 + 2NaOH = Na_2SO_3 + H_2O$$

By making use of above features, the acidic materials such as CO_2, SO_2 could be removed from oxygen. Meanwhile, the desiccants such as anhydrous magnesium perchlorate could be used for removing moisture from oxygen. Heating-decomposition-absorption method is to heat the oxygen to 450℃. Catalyzed by catalyst（such as copper oxide）, hydrocarbon is decomposed into CO_2 and water, and the alkaline substances and desiccant are used to purify oxygen.

When detecting trace sulfur, the pressure of bottled oxygen should not be too low. When the pressure of bottled oxygen is reduced to below 50kg.cm^{-2}, moisture content in the gas will be increased dramatically. When using such oxygen to analyse samples, the magnesium perchlorate in test tube may change color due to deliquesce, and it may cause ossification of indicator, which may lead to inconsistent results of low sulfur detection. Therefore, when analyzing low sulfur samples, the pressure of bottled oxygen should be higher than 880kg.cm^{-2}. The blank values of regular oxygen and high purity oxygen are illustrated in the Table 3.

Table 3. The blank values of regular oxygen and high purity oxygen

Types of oxygen	Weight of Tungsten granular (g)	Value input into PC (g)	Measured value of carbon (w/%)	Measured value of sulphur (w/%)
Regular oxygen	1. 50	1. 50	0. 000 80 0. 000 84 0. 000 79	0. 000 03 0. 000 09 0. 000 02
High purity oxygen	1. 50	1. 50	0. 000 67 0. 000 69 0. 000 64	0. 000 01 0. 000 03 0. 000 00

④Correct detection of blank values: when detecting trace carbon and sulfur in steel, sometimes, system blank value is almost the same with the sample analysis value, even higher than sample analysis value[4]. Therefore, the correct use of blank value method will directly affect the accuracy of the analytical result of trace carbon and sulfur contents in samples. In order to obtain accurate blank value, firstly, the crucibles with the same batch of processing are used with adding fixed amount of fluxing agents; secondly, when detecting blank value, input value should be consistent with the weight of samples to be analyzed; thirdly, the analysis conditions of two analyses should be maintained basically same, especially the same combustion temperature. In detecting blank value and analyzing sample, if the difference of combustion temperature is too large, then the differences of introduced blank values will also be large. Since if the combustion temperature is high, the carbon and sulfur elements of the crucibles materials will be gradually released during the analysis

process, and the CO_2, SO_2 gases deeply absorbed in the tube wall will also be released along with the increase of temperature and the extension of combustion time, and thus the blank values will be increased. Fourthly, the sulfur blank value cyclic detection method [5] is used to correctly measure the total sulfur blank value. The blank value is input into the blank value field of the analyzer, and the analyzer will automatically deduct the blank value during the detection process.

⑤Equipment Calibration: Consensus has been reached that accurate analysis method should take pure compound as the calibration benchmark. International standards ISO 9556 takes sucrose, sodium carbonate, barium carbonate as standard substances of carbon for calibration: ISO 4935 takes potassium sulphate as the standard substance of sulfur for calibration. Although using pure compound is a good way of linear calibration for analyzer, but in practice, the deviation of calibration coefficient has occurred during the analysis process of metal materials such as steel. Since the combustion release of pure compound is different from that of steel, it is not suitable for the analyzer calibrated with pure compound to detect the low content steel. Experience shows, for analyzing a type of material, same materials should be applied for standard substance calibration, and first level standard substance produced recently should be chosen, In addition, it must follow the principle of using high quality standard to calibrate the low one, namely, high quality low-carbon and low-sulfur samples with high contents are used to calibrate and then the low-carbon and low-sulfur samples with relatively lower contents are measured. Both samples have the same matrix components. When conducting detection, it is necessary to pay attention to the consistency of the analysis conditions between the standard substance and samples.

⑥Environmental requirements: Environment temperature and humidity affects the accuracy of analysis result of trace carbon and sulfur contents. In winter, when the temperature is low, it is found that low content sulfur may not be detected or the result of the detection is significantly lower than the actual value. To solve this problem, we may increase the room temperature and firstly burn a couple of waste samples so as to increase the temperature of furnace end, and then conduct the detection of samples. When environmental humidity increases, the moisture in the atmosphere may enter or be absorbed on the tube wall, on surface of stainless strainer, cylinder surface, and gas pipeline wall surface. When sample is burning and releasing heat, it enters into test tube along with gas to be analyzed or condenses at somewhere with low temperature, which will definitely affect the accuracy of analysis. Therefore, when detecting trace carbon and sulfur sample, the room temperature must be maintained at about 25℃, with the relative humidity lower than 60%. Usually, the crucible bracket is raised to its up limit, the pipeline is sealed, so as to prevent atmosphere from entering into the crucible. Sample should be quickly put into place, without being exposed to the air for too long time. Analysis and test of chemical elements of materials involves many contents and many methods, and it is also affected by complicated factors. As an analyst, we should master the professional skills and operate rigorously so as to obtain correct analysis results.

Keywords: carboxyl density; molecular weight; monomer conversion; dispersion ability

Abstract. The effect of carboxyl density (the ratio of acrylic acid and polyoxyethylene ether) upon the performance, molecular weight, and monomer conversion rate of polycarboxylate (PCE) were investigated by slump test, Gel Permeation Chromatography (GPC) and High Performance Liquid Chromatography (HPLC), respectively. The results showed that with carboxyl density increased from 2:1 to 7:1, molecular weight of PCE increased from 7968.5 to 13930.1 and the molecular weight distribution coefficient increased from 1.5 to 2. The HPLC date indicated carboxyl density does not affect the rate of monomer conversion. Test of the fluidity of cement pastes displayed that as carboxyl density was 4.0:1, PCE show the optimal dispersion and dispersion-retaining ability.

Introduction

Polycarboxylates (PCE) are commonly used as superplasticizers to disperse cement particles in concrete and mortar [1]. The research and development of polycarboxylic acid type water-reducers has been one of important direction in concrete admixtures because of their excellent water-reducing rate [2-5]. Currently, it's well known that the dispersing mechanism of these superplasticizers is generally thought to be related to the adsorption of the polymer backbone via carboxylic functional groups and the steric hindrance effect generated by PEG side chains [6]. The dispersion of polycarboxylate superplasticizer for cement was based on their molecular structure[7]. In previous studies, the dispersive force of PCE molecules often was correlated with their anionic charge density calculated from the chemical formula[8]. But because these PCE were polymers with wide molecular weight distribution and it was not easy to characterize their chemical structures, many studies did not concern about the chemical structures of PCE were not analyzed in detail.

To profoundly understand the molecular structure of PCE, specially the charge density of PCE , with their performance in cementitious systems. The dispersion properties of PCE on cementitious systems at different charge density was studied, and then the rate of monomer conversion and the molecular weight was discussed when the charge density of PCE was changed.

1 Experimental

1.1 Synthesis of PCE

The PCE was synthesized according to previous study by aqueous free radical copolymerization of acrylic acid (AA), sodium methylacrysulfonate (SMAS) and polyoxyethylene ether (TPEG-2400). 100g deionized water and 150g TPEG-2400 were added to a 500ml four-necked flask equipped with a condenser, a nitrogen inlet and a stirring bar afterwards and stirred for 15min. The solution was gently heated to 60°C. 1.5g of Ammonium persulphate (APS, initiator) was dissolved in 45 ml deionized water. This solution was designated as Solution I. Separately, variable amount of AA and 0.8g of SMAS (chain transfer agent) with 55g water was then dissolved in 55 ml deionized water. This solution was designated as Solution II. Using two peristaltic pumps, Solutions I and II were fed separately and continuously into the vessel over the periods of 75 min (Sol. I) and 60 min (Sol. II).

After complete the feeding process, the mixture was stirred for several hours under the reaction temperature. At the end, the pH was adjusted to 7 with 30wt% NaOH and the PCE was acquired.

1.2 Testing of monomer conversion

The monomer conversion of PCE was measured by chromatography system (HPLC, Agilent 1100; Column, SinoChrom ODS-BP (C18) 5μm, 4.6mm × 200mm; detector, λ-35 -type UV spectrum, PE company, USA).
Weigh the test sample superplasticizer 0.10g ~ 0.25g, diluted with the mobile phase to 25mL, filtrated with the 0.45μm filter membrane and chromatographic analysis with external standard method.

1.3 Gel Permeation Chromatography (GPC)

Molecular weight of PCE was measured by Gel Permeation Chromatography (GPC, Waters 150C, USA), using the solution of methanol and buffer solution (1/2, v/v) as the eluent. (Column, PL aquagel, 7.8*300 mm, Agilent1100, Agilent Company, USA). The buffer solution was $Na_2B_4O_7$/KCl aqueous solution (pH = 8). Narrow polyethylene glycol (PEG) was used as calibration standards. The GPC detector included the refractive index.

1.4 Mini slump test

Testing of the fluidity of cement pastes was under the national standard GB 8077-2000 “methods for testing uniformity of concrete mixture” and the cement used for the test was HUAXIN P·O 42.5, the w/c ratio was 0.29 and the dosage of the PCE was 0.15% (by percent Weight based on solids cement).

2 Experimental results and analysis

2.1 The effect of carboxyl density on the molecular weight of PCE

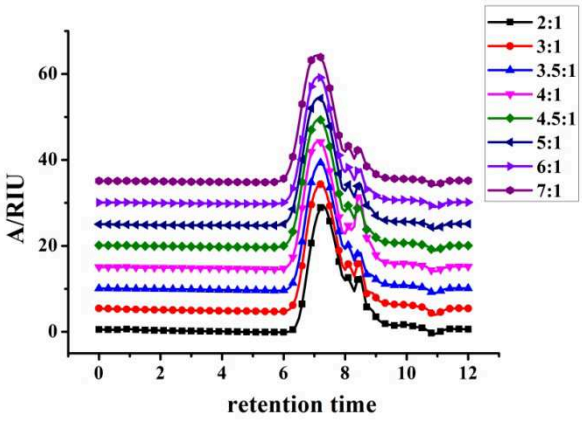

Fig. 2.1 GPC of PCE with different carboxyl density

As can be seen from the GPC results of PCE with different carboxyl density showed in Fig. 2.1 and table 2.1, the molecular weight of PCE become larger and present more broad molecular weight distribution when the carboxyl density increase.

Table 2.1 The calculated result of fig. 2.1

carboxyl density	Mw	Mn	DPI.	Mp
2:1	7968.5	5313.9	1.5	2841.9
3:1	9669.4	5816.6	1.7	3784.8
3.5:1	9949.8	5893.4	1.7	3784.8
4:1	10986.1	6220.9	1.8	5040.4
4.5:1	11797.5	6351.7	1.8	3784.8
5:1	11910.2	6377.4	1.9	5040.4
6:1	11851.2	6360.2	1.9	5040.4
7:1	13930.1	6798.8	2.0	5040.4

This may be caused by two reasons: 1) as the increased of carboxyl density, the charge in the molecular main chain of PCE increase, resulting in the repulsion between the functional groups increases. Wherefore, the molecule stays more open, display larger molecular volume, and show smaller elution volume of the gel permeation chromatogram. Eventually, the greater the molecular weight is calculated out. 2) Since the total molar mass unchanged, thereby the amount of TPEG decrease as the increased of AA. From this, it can be speculated that TPEG possess some certain chain transfer effect.

2.2 Effect of carboxyl density on the monomer conversion of PCE

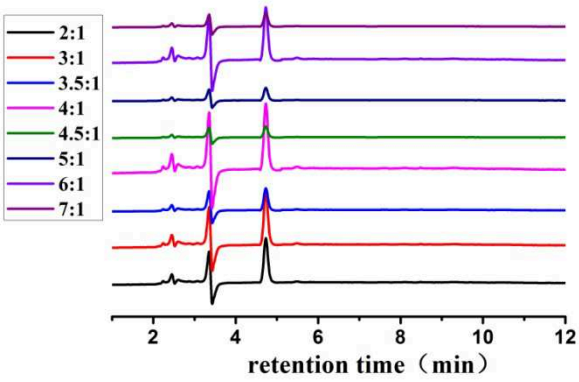

Fig. 2.3 HPLC of PCE with different carboxyl density

Table 2.2 The calculated results of Fig. 2.3

Carboxyl density	2:1	3:1	3.5:1	4:1	4.5:1	5:1	6:1	7:1
Monomer conversion（%）	98.2	99.1	98.8	99.5	99.5	98.5	99.4	98.6

Fig. 2.3 and Table 2.2 show the monomer conversion in the polymerization process of PCE with different carboxyl density. As shown from the results that SMAS and AA almost completely react, which means carboxyl density does not affect the rate of conversion of monomer.

2.3 The effect of carboxyl density on the performance of PCE

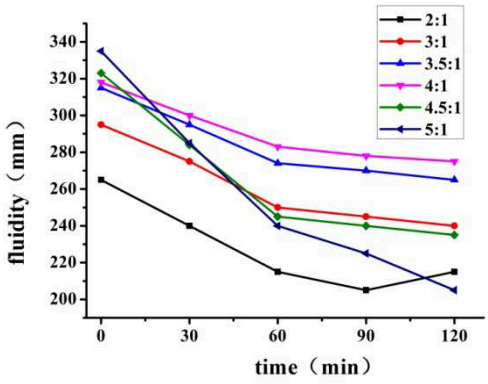

Fig. 2.4 The effect of carboxyl density on the cement paste fluidity over time

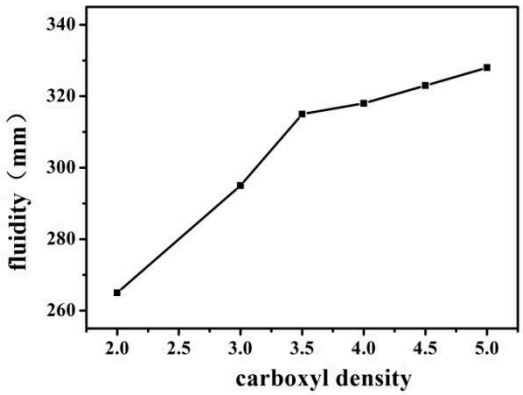

Fig. 2.5 Effects of carboxyl density on initial dispersion performance of PCE

Fig. 2.4 and displays the effects of the carboxyl density on the dispersion capacity and the dispersion retention capacity. Fig. 2.5 displays the effects of the carboxyl density on initial dispersion performance of PCE. It can be seen that when the molar ratio of AA and TPEG-2400 increase from 2:1 to 3.5:1, the fluidity of cement pastes quickly lose from 265mm to 315mm. This tendency would slow down with the further increasing of carboxyl density. The results show that the carboxyl density make a tremendous impact on the dispersant of PCE. It can be ascribed to that AA can provide carboxyl which is of great important to electrostatic repulsion and adsorption capacity acting on the surface of cement particles. As the carboxyl density is low, the electrostatic repulsion and adsorption capacity are insufficient to make a more powerful dispersant in cement. However, the electrostatic repulsion and adsorption capacity are saturated when the carboxyl density is more than 3.5:1.

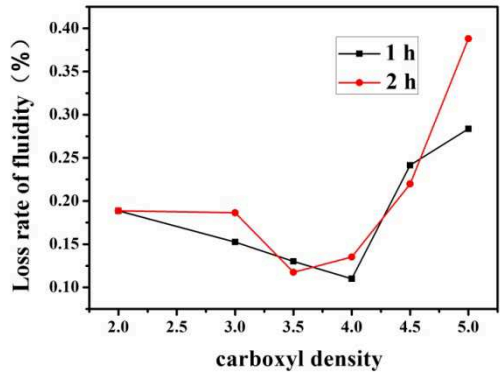

Fig. 2.6 The effect of carboxyl density on the loss rate of the cement paste fluidity

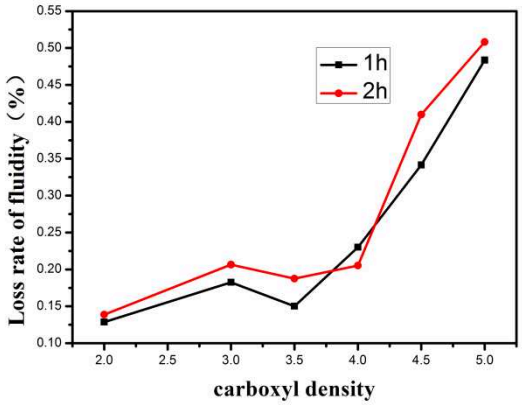

Fig. 2.7 The effect of carboxyl density on the loss rate of the concrete fluidity

The effect of carboxyl density on the loss rate of the cement paste fluidity has been investigated and the results are shown in Fig. 2.6. According to the data above, the PCE exhibits the optimal dispersed retention with the carboxyl density of 4:1. This means the carboxyl density of 4:1 could provide the suited charge density which can benefit the maintenance of electrostatic repulsion. The effect of carboxyl density on the loss rate of the concrete has been investigated and the results are shown in Fig. 2.7. According to the data above, the PCE exhibits the optimal dispersed retention with the carboxyl density of 3.5:1 when it was used in the concrete. the rate of loss of the fluidity on concrete is much greater than on cement.

Conclusion

Based on the research on the molecular weight and monomer conversion by Gel Permeation Chromatography (GPC) and High Performance Liquid Chromatography (HPLC), It was found that the molecular weight of PCE become larger and present more broad molecular weight distribution when the carboxyl density increase. The HPLC date indicated carboxyl density does not affect the rate of monomer conversion. The cement paste fluidity and concrete fluidity when added the PCE show that the loss rate of the fluidity Showing a gradually increasing trend overall. take into account the dispersion and dispersion-retaining ability, it was proposed that the optimal carboxyl density was 4.0:1.

Keywords: Copolymer; Oxidized Starch; Dispersing Ferric Oxide

Abstract. A series of copolymers modified with oxidized starch containing maleic anhydride (MA), styrene sulfonic sodium (SSS) and oxidized starch (OS) were synthesized by the free-radical polymerization. The polymerization is initiated by ammonium persulfate. The effects of content of monomer and initiator, reaction time, reaction temperature on dispersion ability for Fe_2O_3 were investigated by single factor experiment. The dispersion ability for Fe_2O_3 measured through UV spectroscopy was studied. The experimental results show that the copolymer has good dispersion ability for Fe_2O_3 when the mass proportion of monomers is OS:SSS:MA = 1:3:1, the mass fraction of initiator in total monomers is 10 %, reaction time is 5 h, and the reaction temperature is 70 ^oC. The morphology of the copolymer was observed by scanning electron microscope (SEM). The experimental results indicate that the prepared copolymer modified with oxidized starch could be used in the corrosion inhibitor of high temperature water.

Introduction

Recent years, the consumption and pollution of industrial water increase significantly with the rapid development of modern industry, which intensifies shortage of fresh water resource [1]. Internal corrosion of metallic pipes is ubiquitous in drinking water distribution systems [2]. Corrosion scales formed by the accumulation of corrosion products could serve as the breeding ground for microbes and sinks for heavy metals or other contaminants [3]. Ferric oxide deposited cause technical and economical problems such as decreased system efficiency and increased chemical cleaning frequency. On the other hand, ferric oxide deposited on the surface of the recycling cooling water system will not only reduce the heat transfer efficiency, but also lead to breed iron bacteria, which cause corrosion under the scale. So, inhibiting and dispersing ferric oxide deposition becomes very important to the cooling water system.

Copolymers have been applied widely in circulating cooling water treatment contribute to their excellent performances such as inhibiting formation of calcium carbonate scale and dispersing ferric oxide (Fe_2O_3) in water [4]. Among carbohydrate polymers, starch was mainly composed of polyhydric glucose unit. The starch derivants with good performance and multi-varieties could be obtained by chemical, physical or biological deep-processing methods [5].

In this paper, a novel environmentally friendly non-phosphorus copolymer (MA-SSS-OS) was prepared by a free radical solution polymerization with maleic anhydride (MA), styrene sulfonic sodium (SSS) and oxidized starch (OS) as monomers, ammonium persulfate as initiatora. The dispersion ability for Fe_2O_3 measured through UV spectroscopy was studied. To the best our knowledge, this is the first time that dispersing ferric oxide of copolymer modified with oxidized starch is reported.

Experimental section

Synthesis of copolymer modified with oxidized starch. A certain amount of maleic anhydride (MA) was dissolved into appropriate deionized water in a four-necked flask encircled with

water-bath at 80°C. Then, styrene sulfonic sodium (SSS) and the ammonium persulfate initiator were added in turn under ambient pressure, the polymerization was carried out at 80°C for 2h. After that, a copolymer MA-SSS was obtained.

A certain amount of oxidized starch (OS) was dissolved into deionized water containing to acetic acid in a four-necked flask encircled with water-bath at 80°C and the solution was stirred for about 2h. Then, the solution was added into the above copolymer. The mixture was stirred for about 5h and was filtered. The sample was heated at 55°C under vacuum for 2h to remove residual solvent. The copolymer (MA-SSS-OS) modified with oxidized starch was obtained.

Dispersion ability for ferric oxide. The dispersion ability for ferric oxide measured through UV spectroscopy as follows: the mixture containing 1.5 mL $CaCl_2$ solution ($0.15mol \cdot L^{-1}$) and 2.5mL $FeSO_4$ ($0.009mol \cdot L^{-1}$) was prepared. To each 100 mL portion of solution, different quantities of the copolymers were added and treated as the test solution. The other portion without the copolymer served as the blank. The pH was maintained at 9 and the temperature at 50°C. After the test period of 5h, the supernatant solutions were analyzed for iron ion retained in the solution at the wavelength of 420nm. The ultimate dispersion ability for ferric oxide (η) was obtained by the formula as below:

$$\eta = \frac{T_0 - T_2}{T_0 - T_1} \times 100\% \qquad (1)$$

where T_0 was the transmittance without heating and copolymer in the solution for 5h; T_1 was the transmittance without copolymer in the solution after heating for 5h; T_2 was the transmittance in presence of copolymer after heating for 5h.

Results and discussion

Effect of mass ratio of OS:SSS on the dispersion ability for ferric oxide. The effect of the mass ratio of OS and SSS on the dispersion ability for ferric oxide (η) was obtained at the fixed reaction time 5 h, temperature 70°C, OS:MA = 1:1(mass ratio) and the amount of initiator 10 %. The results are listed in Table 1.

Table 1. The effect of mass ratio of OS to SSS on dispersion ability for ferric oxide

OS:SSS	1:2	1:2.5	1:3	1:3.5	1:4
η (%)	57.14	66.40	98.80	82.14	76.00

As can be seen from Table 1, the η value increases with increasing mass ratio of OS:SSS. When the mass ratio of OS:SSS is 1:3, the MA-SSS-OS has the highest dispersion ability for Fe_2O_3, and the η value is 98.80%. However, with the mass proportion of OS and SSS further increasing, the η value decreases. Hence, the mass proportion of OS and SSS of 1:3 is chosen for the preparing copolymer in this reaction system.

Effect of mass ratio of OS:MA on the dispersion ability for ferric oxide. The effect of the mass ratio of OS and MA on the dispersion ability for ferric oxide was obtained at the fixed reaction time 5 h, temperature 70°C, OS:SSS=1:3(mass ratio) and the amount of initiator 10 %. The results are listed in Table 2.

Table 2. The effect of mass ratio of OS to MA on dispersion ability for ferric oxide

OS:MA	1:0	1:0.5	1:1	1:1.5	1:2
η (%)	65.87	87.70	98.80	76.98	56.35

As shown in Table 2, the η value increases with increasing mass ratio of OS:MA. When the mass ratio of OS:MA is 1:1, the MA-SSS-OS has the highest dispersion ability for Fe_2O_3, and the η value is 98.80%. However, with the mass proportion of OS and MA is further increasing, the η value decreases. Hence, the mass proportion of OS and MA of 1:1 is chosen for the preparing copolymer in this reaction system.

Effect of reaction time on the dispersion ability for ferric oxide. The effect of the reaction time on the dispersion ability for ferric oxide was obtained at the fixed temperature 70°C, OS:SSS:MA=1:3:1(mass ratio) and the amount of initiator 10 %. The results are listed in Table 3.

Table 3. The effect of reaction time on dispersion ability for ferric oxide

Time (h)	3	4	5	6	7
η (%)	58.85	72.18	98.80	97.62	92.86

As shown in Table 3, the η value increases with increasing reaction time. When reaction time is 5h, the MA-SSS-OS has the highest dispersion ability for Fe_2O_3, and the η value is 98.80%. So, 5h is the best reaction time.

Effect of amount of initiator on the dispersion ability for ferric oxide. The effect of the amount of initiator on the dispersion ability for ferric oxide was obtained at the fixed reaction time 5 h, temperature 70°C and OS:SSS:MA=1:3:1 (mass ratio). The results are shown in Table 4.

Table 4. The effect of amount of initiator on dispersion ability for ferric oxide

Initiator (%)	4	6	8	10	12
η (%)	68.65	74.60	92.86	98.80	93.65

As can be seen from Table 4, the η value increases with increasing amount of initiator. At the amount of initiator is 10%, the polymer OS-SSS-MA has the highest dispersion ability for Fe_2O_3, and the η value is 98.80%. From the obtained results, the dispersion ability for Fe_2O_3 changes little after the amount of initiator is higher than 10%.

Effect of reaction temperature on the dispersion ability for ferric oxide. The effect of the reaction temperature on the dispersion ability for ferric oxide was obtained at the fixed time 5h, OS:SSS:MA=1:3:1(mass ratio) and the amount of initiator 10 %. The results are listed in Table 5.

Table 5. The effect of reaction temperature on dispersion ability for ferric oxide

Temperature (°C)	50	60	70	80	90
η (%)	64.21	73.41	98.80	89.52	80.16

As shown in Table 5, the η value increases with increasing reaction temperature. When reaction temperature is 70 °C, the MA-SSS-OS has the highest dispersion ability for Fe_2O_3, and the η value is 98.80%. Then the dispersion ability for ferric oxide of the copolymer decreases with increasing reaction temperature.

In conclusion, the optimum condition of preparing copolymer is: the mass proportion of monomers is OS:SSS:MA=1:3:1; the mass fraction of initiator in total monomers is 10 %; reaction time is 5 h and the reaction temperature is 70 °C. At the optimum condition, copolymer has the highest dispersion ability for Fe_2O_3 and the value is 98.80 %. The obtained results indicate that the copolymer is efficient Fe_2O_3 dispersion agent and could be used in the system of high hardness water.

SEM micrographs of OS and copolymer. The SEM micrographs of the OS (a) and prepared copolymer (b) are shown in Figure 1. In most cases, surface morphology of materials is of great importance for many technical applications requiring well-defined surfaces or interfaces. The SEM micrograph of OS (Figure 1(a)) shows regular spherical shape. After copolymerization, the copolymer has regular rhombohedron shape. (Figure 1(b)). It might be attributed to the polar difference between OS and copolymer and the destruction of the intermolecular hydrogen bonds and the crystalline regions of OS, which indicates intuitively that the copolymer side chains are introduced into OS main chains.

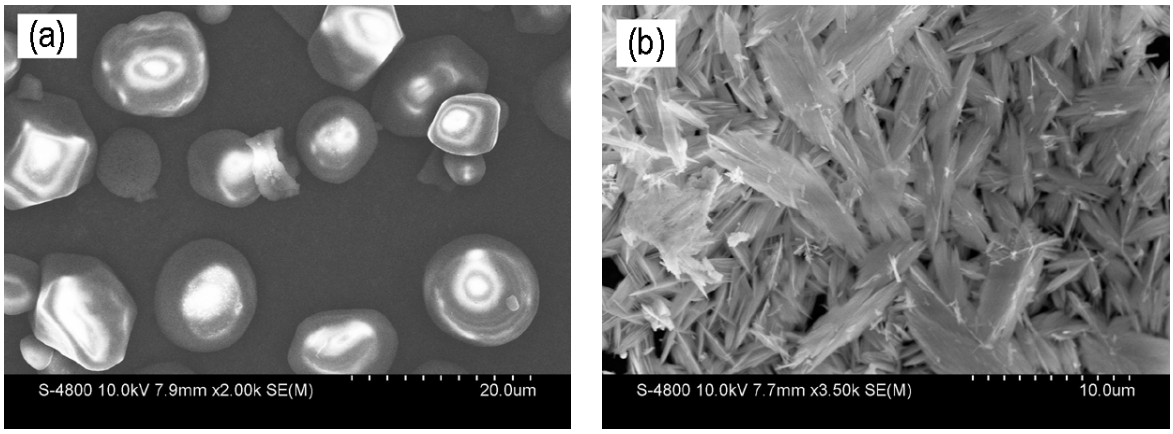

Fig.1. SEM micrographs of OS (a) and copolymer (b)

Conclusions

A novel copolymer modified with oxidized starch was prepared. The optimal condition for the preparation of copolymer is: a OS:SSS mass ratio of 1:3, a OS:MA mass ratio of 1:1, a mass fraction of initiator of 10 %, a reaction time of 5 h and a reaction temperature of 70 ^{o}C. At the optimum condition, copolymer has the highest dispersion ability for Fe_2O_3 and the value is 98.80 %. The SEM micrograph of copolymer indicates that after copolymerization, the copolymer has regular rhombohedron shape. The obtained results indicate that the copolymer is efficient Fe_2O_3 dispersion agent and could be used in the system of high hardness water.

Keywords: Attapulgite; Corrosion Inhibitor; Dispersing Ferric Oxide

Abstract. The corrosion inhibitor modified with acid activated attapulgite (CIATP) was prepared with acid activated attapulgite (HATP), styrene sulfonic sodium (SSS), maleic anhydride (MA) as monomers, water as solvent and ammonium persulfate as initiator. The effects of mass ratio of monomer, reaction temperature, the content of initiator and reaction time of preparing CIATP were investigated. The influences of the prepared CIATP concentration, time, pH and temperature of the system on the dispersing ferric oxide efficiency were also investigated. The obtained results showed that the prepared CIATP had excellent efficiency of dispersing ferric oxide, and nearly 98.98 % of dispersing ferric oxide efficiency was obtained. The experimental results indicate the corrosion inhibitor CIATP could be used in the corrosion inhibitor of high temperature water.

Introduction

At the present time, some of the demand for better utilization of the limited water supplies is due to population growth and increasing development [1]. Scale formation is a serious problem encountered in many industries including oil or gas production, water transport, power generation and batch precipitation [2]. Ferric oxide deposited on the surface of the recycling cooling water system will not only reduce the heat transfer efficiency, but also lead to breed iron bacteria, which cause corrosion under the scale. The most common and effective scale control method is the use of scale inhibitors. Copolymer has been used satisfactorily as a specific scale inhibitor in the circulating cooling water systems, because of its strong complexation of functional groups and superior dispersion characteristic of macromolecule [3]. Attapulgite (ATP) is a kind of crystalline hydrated magnesium aluminum silicate with unique three dimensional structures and has a fibrous morphology with exchangeable cations and reactive -OH groups on its surface [4].

In this work, corrosion inhibitor (CIATP) was synthesized with acid activated attapulgite (HATP), styrene sulfonic sodium (SSS), maleic anhydride (MA) as monomers, water as solvent, ammonium persulfate as initiator by the free-radical polymerization. The conditions of preparing CIATP and performance of dispersing ferric oxide were investigated.

Experimental section

Preparation of corrosion inhibitor polymer modified with acid activated attapulgite (CIATP). The ATP (10.0g) was deposed in HCl (100mL, 2.0mol/L) in a flask, and stirred magnetically for 30min at 30^{o}C. Then, the solution was vibrated with the aid of ultrasonic instrument for 10min. After removing the supernatant, the residue was centrifuged and washed with distilled water several times until pH =7 and drying under vacuum at 105 ^{o}C. After grinding, the acid activated attapulgite (HATP) solid was obtained and stored in desiccator. A certain amount of HATP was dissolved in 15 mL of water solution in a four-necked flask encircled with water-bath at 80 ^{o}C and the solution was stirred for about 2h. Then, SSS, MA and initiator ammonium persulfate mixed solution was dropped slowly, and the reaction was left for 5 h under slow agitation. The corrosion inhibitor polymer CIATP was obtained by evaporation- crystallization process.

The performance of dispersing ferric oxide. The dispersion ability for ferric oxide measured through UV spectroscopy as follows: the mixture containing 1.5 mL CaCl2 solution (0.15mol·L-1) and 2.5mL FeSO4 (0.009mol·L-1) was prepared. To each 100 mL solution, different quantities of the copolymers were added and treated as the test solution. The other portion without the copolymer served as the blank. The pH was maintained at 9 and the temperature at 50°C. After the test period of 5h, the supernatant solutions were analyzed for iron ion retained in the solution at the wavelength of 420nm. The ultimate dispersion ability for ferric oxide (η) was obtained by the formula as below:

$$\eta = \frac{T_0 - T_2}{T_0 - T_1} \times 100\% \quad (1)$$

where T_0 was the transmittance without heating and copolymer in the solution for 5h; T_1 was the transmittance without copolymer in the solution after heating for 5h; T_2 was the transmittance in presence of copolymer after heating for 5h.

Results and discussion

Effect of HATP content on the performance of dispersing ferric oxide. Fixed SSS:MA=3:1 (mass ratio), reaction time of 4 h, the reaction temperature of 80oC and the content of initiator 12.0 %, effects of the HATP content on the performance of dispersing ferric oxide are listed in Table 1. The dispersing efficiency of 85.27 % to Fe_2O_3 is obtained when the content of HATP is 11.0 %. This is mainly because graft copolymerization between HATP and organics exist the saturation adsorption quantity; if it is exceeded, the redundant HATP would suspend in the copolymerization system and solutions. Therefore, the chosen content of HATP is 11.0 % in the experiment.

Table 1. The effect of the HATP content on the performance of dispersing ferric oxide

HATP (%)	4.0	7.0	11.0	14.0	17.0
η (%)	48.74	66.77	85.27	53.61	42.32

Effect of mass ratio of HATP:SSS on the performance of dispersing ferric oxid. Fixed the content of HATP of 11.0 %, HATP:MA=1:1.7, reaction time of 4 h, the reaction temperature of 80°C and the content of initiator 12.0 %, effect of mass ratio of HATP:SSS is shown in Table 2. When the HATP:SSS is 1:4, the corrosion inhibitor has the best performance of dispersing ferric oxide. Hence, the HATP:SSS of 1:4 is chosen for further experiments.

Table 2. The of mass ratio of HATP:SSS on the performance of dispersing ferric oxide

HATP:SSS (mass ratio)	1:3	1:4	1:5	1:6	1:7
η (%)	70.85	85.27	82.45	69.28	65.52

Effect of the mass ratio of HATP:MA on the performance of dispersing ferric oxide. Fixed the content of HATP of 11.0 %, HATP:SSS=1:4, reaction time of 4 h, the reaction temperature of 80°C and the content of initiator 12.0 %, effect of the mass ratio of HATP:MA is shown in Table 3. The dispersing efficiency of 85.27% to Fe_2O_3 is obtained when the mass proportion of HATP:MA is 1:1.3. Hence, the HATP:MA of 1:1.3 is chosen in the experiment.

Table 3. The effect of the mass ratio of HATP:MA on the performance of dispersing ferric oxide

HATP:MA (mass ratio)	1:1	1:1.3	1:1.7	1:2	1:2.3
η (%)	42.63	85.27	82.45	51.72	42.95

Effect of mass content of initiator on the performance of dispersing ferric oxide. Fixed the content of HATP of 11.0 %, HATP:SSS:MA=1:4:1.3, reaction time of 4 h and the reaction temperature of 80°C, effect of mass content of initiator is shown in Table 4. At the content of initiator is 10.0 %, the corrosion inhibitor shows the best performance of dispersing ferric oxide, then the dispersing ferric oxide efficiency of the corrosion inhibitor decreases with increasing content of initiator. This is mainly because the initiator content is too little, the relative molecular

weight of the corrosion inhibitor is too big and the molecular chain of the corrosion inhibitor is too long. The carboxylic acid group on either side of the molecular chain can absorb more ferric oxide, and influence the performance of dispersing ferric oxide. Hence, the content of initiator of 10.0 % is chosen in the experiment.

Table 4. The effect of mass content of initiator on the performance of dispersing ferric oxide

Mass content (%)	6.0	8.0	10.0	12.0	14.0
η (%)	38.53	65.83	86.52	85.27	78.06

Effect of reaction temperature on the performance of dispersing ferric oxide. Fixed the content of HATP of 11.0 %, HATP:SSS:MA=1:4:1.3, reaction time of 4 h and the content of initiator 10.0 %, effect of reaction temperature is shown in Table 5. The highest dispersing efficiency of 90.60 % to Fe_2O_3 is obtained when the temperature is 60 ^oC. Hence, the reaction temperature of 60 ^oC is chosen in the experiment.

Table 5. The effect of reaction temperature on the performance of dispersing ferric oxide

Temperature (^oC)	50	60	70	80	90
η (%)	59.87	90.60	77.12	66.14	64.89

Effect of reaction time on the performance of dispersing ferric oxide. Fixed the content of HATP of 11.0 %, HATP:SSS:MA=1:4:1.3, reaction temperature of 60^{o}C and the content of initiator 10.0 %, effect of reaction time is shown in Table 6. When the reaction time is 5h, the corrosion inhibitor has the highest dispersing ferric oxide efficiency which the value is 94.65%. With the extension of reaction time, dispersing ferric oxide efficiency of the corrosion inhibitor changes little. Therefore, 5 h is the balance point of copolymerization, and is chosen in the experiment.

Table 6. The effect of reaction time on the performance of dispersing ferric oxide

Time (h)	2	3	4	5	6
η (%)	47.65	79.94	93.73	94.65	94.57

In conclusion, the optimum conditions of preparing CIATP are obtained as follows: the content of HATP of 11.0 %, ATP:SSS:MA=1:4:1.3 (mass ratio), reaction temperature of 60 oC, the content of initiator in total monomers 10.0 % and reaction time of 5 h.

Influence of the CIATP concentration on the dispersing ferric oxide efficiency. The influence of the CIATP concentration on the dispersing ferric oxide efficiency is shown in Figure 1(a) at the fixed the temperature of 50^{o}C, the time of 5 h, Fe^{2+} concentration of 0.01 mol/L and the pH value of 9.0. When the CIATP concentration is 0.16 g/L, the highest dispersing ferric oxide efficiency is reached; and the value is 95.86 %. However, the dispersing ferric oxide efficiency decreases when the CIATP concentration is beyond 0.16 g/L. This is mainly because the CIATP contains hydroxide radical and is able to coordinate with metal ions to generate stable complex, thereby preventing ferric oxide from precipitation. Moreover, the CIATP contains carboxyl and sulfonic acid groups; these active groups can bond with Fe^{2+} in the solution to form chelates which can be adsorbed on the surface of the corrosion inhibitor. With the increase of the CIATP concentration, the bond of corrosion inhibitor with the Fe^{2+} ions increases; and the dispersing ferric oxide efficiency increases. When the CIATP concentration is beyond the optimal value; such as 0.16 g/L in this experiment condition, the Fe^{2+} ions in the solution almost are chelated. The dispersing ferric oxide efficiency does not increase, but also the efficiency decreases, which is due to the flocculation of the copolymer by the polarity action of active groups.

Influence of time on the dispersing ferric oxide efficiency. Fixed the temperature of 50 ^oC, the CIATP concentration of 0.16 g/L, the Fe^{2+} concentration of 0.01 mol/L and the pH value of 9.0, the influence of time on the dispersing ferric oxide efficiency is shown in Figure 1(b). When the time is 3 h, the CIATP has the highest dispersing ferric oxide efficiency; and the value is 98.07 %. After 8 h, the dispersing ferric oxide efficiency is stable. This may be due to the fact that at a certain time, the reaction of dispersing ferric oxide has completely finished, so there is a little effect even with the extension of bath time.

Influence of temperature and pH on the dispersing ferric oxide efficiency.

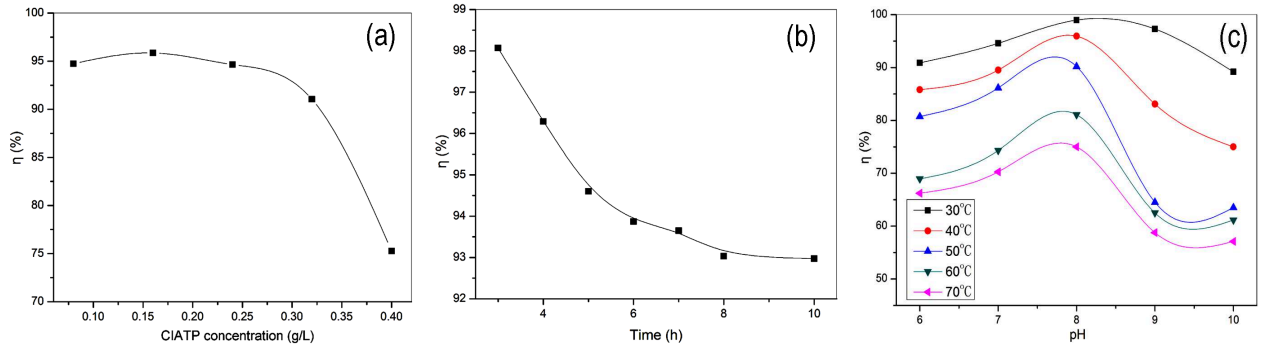

Fig.1. The experimental results

Fixed the time of 5 h, the CIATP concentration of 0.16 g/L, the Fe2+ concentration of 0.010 mol/L, influences of temperature and pH on the dispersing ferric oxide efficiency are shown in Figure 1(c). With temperature rising, the dispersing efficiency decreases. This can be ascribed that with the increase of water temperature, microcrystal particles move more quickly and the speed of particle colliding with each other is even faster, which accelerates the formation of scale easily. From the Figure 1(c), the dispersing ferric oxide efficiency increases steeply with increasing of pH value of the solution from 6.0 to 8.0. Then, the dispersing ferric oxide efficiency decreases with the increase pH value of the solution, which indicates that the dispersing ferric oxide efficiency for the CIATP is influenced greatly by the system acidity. The results show that the groups on the CIATP, such as carboxyl, phosphite and sulfonic acid groups have better dispersing ferric oxide efficiency in basic solution than that in acidic solution. When pH value of the solution is 8.0, the CIATP has the highest dispersing ferric oxide efficiency, and the value is up to 98.98%.

Conclusions

A novel corrosion inhibitor polymer modified with acid activated attapulgite (CIATP) was prepared by a free radical solution polymerization. The optimum conditions of preparing CIATP were obtained as follows: the content of HATP of 11.0 %, ATP:SSS:MA=1:4:1.3 (mass ratio), reaction temperature of 60oC, the content of initiator in total monomers 10.0 % and reaction time of 5 h. The dispersing ferric oxide efficiency was investigated and the result was up to 98.98%. The experimental result shows that the prepared corrosion inhibitor CIATP has a high capacity of dispersing ferric oxide and could be used in the corrosion inhibitor of recycled water.

Keywords: Stir bar; Plasticizer; Polymerization; High performance liquid chromatography

Abstract. An in-situ polymerization method was used for the preparation of a novel stir bar based on neodymium magnet ($Nd_2Fe_{14}B$) powders. The processes were carried out by several steps including the enwrapping of $Nd_2Fe_{14}B$, the modification of the enclosed $Nd_2Fe_{14}B$, and the form of organic polymers on the surface of the modified powders. It was successfully used to enrich the plasticizers in water sample by stir bar sorptive extraction (SBSE). The experimental conditions for SBSE, such as the choice of extraction sorvents, salt concentration, extraction and desorption time were optimized in detail. Coupled to high performance liquid chromatography (HPLC), the recoveries of dibutyl phthalate (DBP), dimethyl phthalate (DMP), diethyl phthalate (DEP) were 89.2%~92.1%**,** 91.9%~96.6% and 94.3%~96.7%, respectively; the linear relationships between the concentration 5 μg/L and 800 μg/L for DBP were obtained; the limits of detection ranged from 0.09 μg/L to 0.21 μg/L in the optimal conditions.

Introduction

Food, beverage and bottled water are generally the major sources of human exposure to PAEs due to the wide addition during their industrious production [1]. Effectively detection and supervision of the composition and content in different samples is very important and necessary, current research efforts are directed towards the development of simple and sensitive analytical methods, capable of accurately determining the trace quantities of PAEs in different complex samples. Some preconcentration techniques were generally selected as the sample preparation procedures, based on liquid-liquid extraction, solid-phase extraction (SPE), and solid-phase microextraction (SPME), followed by gas chromatography (GC), liquid chromatography (LC), capillary electrophoresis (CE), or gas chromatography and mass spectrometry (GC-MS) [2-4]. SBSE, as well as SPE or SPME, are popular sample preparation techniques based upon sorptive extraction. It integrates extraction and stirring in the same device, avoiding potential analytes losses due to the introduction of an external stirring device. In this paper, a common stir bar based on organic-based polymers was initially fabricated by bulk polymerization. The obtained magnetic stir bar was applied to preconcentrate and determine some typical PAEs such as DBP, DEP and DMP (see **Fig.1**) in the lake water by HPLC, and better recoveries in three spiked levels were obtained under the optimal conditions.

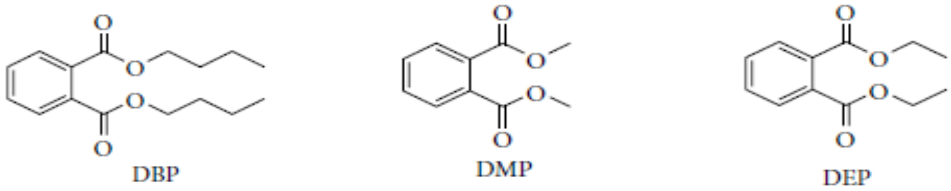

Fig.1. The molecular structures of the studied PAEs

Experimental

Instrument

HPLC experiments were carried out by a P1201 HPLC system (Elite Analytical Instrumental Co. Ltd., Dalian, China), equipped with an injector with a 20 μL quantitative tube (Rheodyne 7725i), and a detector with a changeable ultraviolet-visible wavelength in the range of 190-700 nm. A chromatographic column packing with ODS-C_{18} (150 ×4.6 mm，5 μm) was used as the stationary phase and a binary solvent of ACN/H_2O (V/V=80/20) was used as the mobile phase，the flow rate is 1ml/min, the detection wavelength was set at 224nm, detection was carried out at room temperature. Quanta 200 Scanning Electron Microscopes (FEI，Hillsboro，Oregon，USA）, magnetic separation rack(Zhengzhou Innosep Biosciences Co. Ltd.), HH-4 thermostat water bath (Henan Zhicheng Scientific Development Co.Ltd.), a BOS60-S Electric Mixer with digital screen（Jinghua Huaou Experimental Instrument Factory).

Materials and Chemicals

99.5% α-methacrylic acid（MAA）, 98% γ-methacryloxypropyltrimethoxysilane (MPTMS), 98% ethylene dimethacrylate (EDMA), tetraethyl orthosilicate (TEOS), 99.5% acetone, methanol (MeOH), acetonitrile (ACN), toluene, CH_3COOH, NaCI, CH_3CI were purchased from Beijing Bailingwei Chemical Reagent Company and Tianjing Chemical Reagent Company, China. 2, 2-azobisisobutyronitrile (AIBN, analytically pure) was purchased from Tianjin Guangfu Fine Chemical Research Institute; EDMA were extracted with 5%-10% aqueous sodium hydroxide and water before use. 99.5% dibutyl phthalate (DBP), 99.5% dimethyl phthalate (DMP), 99.5% diethyl phthalate (DEP) were purchased from Sinapharm Chemical Reagent Beijing Co.,Ltd. Rb-Fe-B (sintered NdFeB magnet), with positive component ratio of Nd to Fe in the main phase $Nd_2Fe_{14}B$ 1 to 7, density is ≥ 7.5, remanence induction strength classically 12.5 kilogauss (KG)s, and particle size ≤ 30 μm, was provided by Beijing Zhong Ke San Huan Hi-tech Co., Ltd. Other reagents are analytically pure and water used in the experiment was double distilled water.

Results and discussion

Preparation of the magnetic stir bar

The preparation of the monolithic stir bar was carried out step by step as follows [5]: Firstly, the purchased magnetic powder was immersed in acetone and alkaline solution for 30 min, respectively, to remove the organic compounds from the surface, followed by vacuum drying for further use. The monolithic stir bars were synthesized by thermal polymerization in the glass tube using the modified $Nd_2Fe_{14}B$ magnetic particles as the starting materials. Twenty grams of the pretreated dried magnetic powder was put into 50 mL acetone and 4 mL distilled water, 5 mL ammonia solution and 5 mL TEOS were added dropwisely while stirring (500 rpm) at room temperature, then stirred for additional several hours. Magnetic powders were collected using magnetic separation rack, washed with distilled water and vacuum dried at 120 °C to obtain SiO_2 coated magnetic powders for next modification. γ-MAPS (20 mmol/L) was put into toluene to make 10% (v/v) solution, and 20 g magnetic powder was put into this solution in a conical flask to be shaken for 2 h in order to obtain more unsaturated double bonds on the surface of the enclosed magnetic powders. Finally, the monoliths were formed on the surface of $Nd_2Fe_{14}B@SiO_2$ by the copolymerization of vinyl end groups with functional monomer, BMA, EDMA, AIBN.

It should be noted that the modified $Nd_2Fe_{14}B@SiO_2$ microparticles can be further cross-linked due to the broken vinyl end groups during thermal polymerization, so as to form a magnetic monolithic bar in the glass tube in situ. Finally, MAA (4 mmol, 0.341 mL) were dissolved into 5 mL chloroform, ultrasonic vibrated for 15 min, and then filled with nitrogen following by 30 min standing for molecular self-assembling. After that, EDMA (30 mmol, 5 mL) and ethyl cellulose (EC) (0.1 g) (accounts for 1% of the total volume) were added, ultrasonic vibrated until EC was fully dissolved, and then added with AIBN (0.03 g). The prepared solution (480μL) and the modified magnetic powder (2.48 g) were filled into a glass tube (0.4 cm in diameter, 8 cm in length) in 6 times (solution was filled before the magnetic powders). The filled glass tube was ultrasonic

vibrated for 10 min to increase the compaction degree. Then the tube was sealed with rubber plug, and incubated for 42 h in 80 °C water bath. After thermal polymerization, the glass tube was cracked and the the resulted stir bar was cut into several parts with a length of 1 cm. The magnetic stir bar self stirred for 12 h in methanol/acetic acid (v/v=9:1) solution, and the solution was changed every 3 h. Then, the stir bar self stirred for 6 h in pure methanol solution, and the solution was changed every 2 h, until no impurity peak can be detected.

Optimization of SBSE Extraction

Optimization of SBSE procedure was carried out in a 5 mL vial sealed with a silicone-rubber septum cap at a constant stir speed of 400 rpm. It was accomplished by directly insert a prepared stir bar in 0.5 μg/mL DBP standard solution for this investigation. Moreover, the desorption was carried out by moving the stir bar in a 1 mL vial, followed by the addition of 200 μL desorption solvent and ultronsonication about 20 min. Evaluation of the extraction parameters in different conditions was carried out using HPLC peak area which indicated the analyte concentration. Extraction and elution reagents, stirring rate, extraction and elution time, salt concentration and pH were, respectively, optimized for the SBSE procedure in detail. The final optimal condition was finally selected as follows: water is selected the optimal extraction solution, compared with hexane, toluene, chloroform and ACN, and extraction time 70 min, 15% (w/w) NaCl was selected as the optimal salt concentration, 200 μL ACN as desorption solution, ultrasonic, and desorption for 20 min.

The absorption curve of the prepared stir bar

The extraction amount of the stir bar was investigated using a series of DBP standard solutions in the range of 5-2500 μg/L. As shown in **Fig.2**, it indicated that the peak area of DBP increased continuously along with the increase of concentration for the resulted stir bar. Overall, the extraction reached equilibrium when the concentration was up to 800 μg/L, with a BPA peak area about 400 mV·s or so.

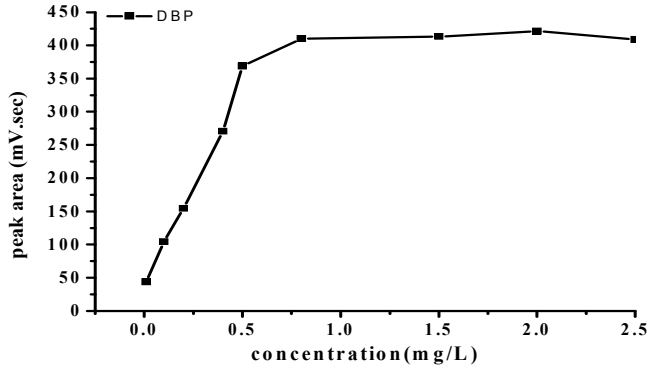

Fig.2. DMP adsorption curve of stir bar in the concentration range of 0-2.5 mg/L

The calibration curve was constructed using the areas of the chromatographic peaks measured (y) at different increasing levels (x) for the mixture of DBP, DEP and DMP. Good linearity was observed for three analytes, respectively, in the selected concentration range of 5-800 μg/L. The regression equations and limited of detection (LOD, 3S/N) were calculated as follows: y_{DMP}=89.895x+13.11 (R=0.998, LOD=93 ng/L); y_{DEP} =84.573x+11.3 (R = 0.996, LOD=150ng/L); y_{DBP} =85.527x+8.5813 (R=0.998, LOD=210 ng/L).To demonstrate the suitability and potential application of the developed SBSE-HPLC method for real analysis, the recovery experiments were carried out by spiking three different levels of the mixture of DBP, DEP and DMP into the bottled water. The accuracy and precision of the method were assessed by performing analyses of spiked samples in five replicates. Higher relative recoveries in the range of 91.9-96.6%,94.3-96.7% and 89.2-92.1% for DMP, DEP and DBP were obtained at three spiked concentration of 100, 200 and 400 μg/L, respectively, corresponding to their relative standard deviations (RSD, n = 5) of 2.5-4.1%,

3.2-5.4% and 2.9-4.7% accordingly. The relative chromatograms were shown in Fig.3, the real sample of lake water (c) was detected by HPLC, but no PAEs was found compared with the retention time of the mixed standards of DBP, DEP and DMP (b). It should be noted that some peaks from impurities were removed after the real sample were pre-concentrated by SBSE procedure (see b). Furthermore, after the spiked sample was subject to the SBSE (a) procedure, the sensitivities for three analytes were greatly enhanced owing to the enrichment of the stir bar.

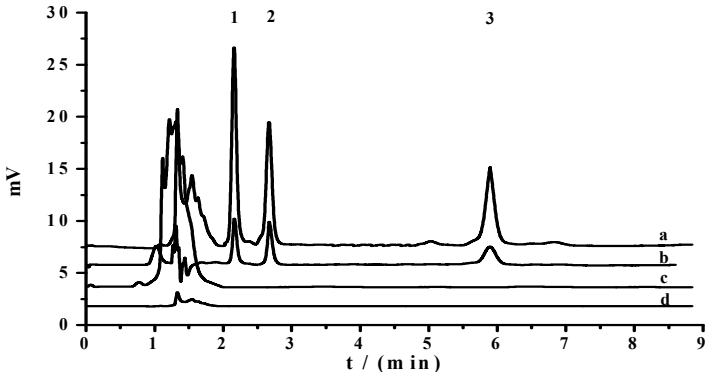

Fig.3. HPLC chromatograms of lake water sample

(a) lake water spiked with 0.1mg/L DMP, DEP and DBP, respectively; (b) 0.1mg/L mixed standards of DMP, DEP and DBP; (c) lake water; (d) lake water after pretreatment by SBSR; Peak identification: 1.DMP, 2.DEP, 3.DBP.

Conclusions

A novel stir bar based on organic polymers was successfully prepared and used for the detection of typical PAEs coupled to HPLC. It will potentially be used for the pretreatment of general samples in the application of SBSE techniques in the future.

Keywords: simulation, Chemical Vapor Deposition diamond film, Kinetic Monte Carlo method

Abstract. The growth of CVD diamond film was simulated by using revised KMC method. The simulation was conducted at CH_3 radical concentration (0.01%-0.03%) and atomic hydrogen concentration (0.01%-0.5%). The results showed that: The CVD diamond film growth under revised KMC method is superior, which is in good agreement with the experimental results. The concentration of CH_3 ([CH_3]) and the concentration of atomic H ([H]) can produce important effects on the film deposition rate, surface roughness and the concentration of atom H embedded in the film.

Introduction

CVD (Chemical Vapor Deposition) diamond film is a material of many unique properties. These properties have created potential opportunities for diamond film in mechanical, electronic, thermal, optical and chemical applications among others [1][2][3]. Even though quick progress has been made in the CVD diamond film growth [4] [5], however, the growth mechanism of diamond film is not well understood yet, especially the precise relationship between processing conditions [6].

In our previous study, the growth of CVD diamond film in C-H system and C-H-Cl system was simulated by using revised Kinetic Monte Carlo (KMC) method [7][8]. In the article, the growth of CVD diamond film will be simulated under a new process.

Method

Diamond film is usually deposited at sub-atmospheric pressure (20 Torr). The typical deposition conditions are as following: A feed gas of H_2 containing a small fraction of hydrocarbon precursor (often 1% CH_4 by volume) is supplied to the growth reactor and activated by exposure to a heat source. The growth substrate is in contact with this activated gas and diamond deposition occurs mainly by the reaction of the substrate with H, C, CH, CH_2, C_2 and C_2H_2 etc. according to a set of chemical reactions. These chemical reactions are all included in a certain chemical reaction model [9] we term it as B-S model hereafter.

The film growth simulation starts on an H-passivated diamond substrate. All lattice sites are fixed at their diamond cubic positions. The temporal evolution of the diamond surface is simulated by means of a modified KMC method [8]. Within this method, one surface reaction is allowed to take place at one surface site during each time step. At each time step, a chemical reaction is selected among all possible reactions, which can occur under B-S model [9]. After a reaction has occurred, the total number of possible reactions is updated and the procedure is repeated. Traditional CVD diamond film growth process conditions are as following: Substrate temperature T_s=1200K, concentration of atom hydrogen [H] =0.2%, [H_2] =88.9%, [CH_3] =0.02%, [C_2H_2] =0.2%, and P=20Torr. We call this the standard case.

In the paper, we introduce a new growth process of CVD diamond film. The new growth model is carried out as follows: at first, the concentration of CH_3 and C_2H_2 is set to 0.006% and 0.07%, much lower than those in standard case, respectively. Other parameters are in the same value with the standard case. In the whole process, we assume that all the parameters in this step are invariable. CVD diamond film grows in such condition for a period of time (usually the time of some islands formed on the growth surface). Then the concentration of CH_3 and C_2H_2 is increased to standard case.

The film is allowed to grow in the z-direction while periodic boundary conditions are applied in the x and y directions in order to avoid the film edge affects. The size of the computational lattice in x-y plane, where $d_{(u\ v\ w)}$ is the spacing of the (u v w) diamond planes. The substrate used in this study is partially shown in Fig. 1.

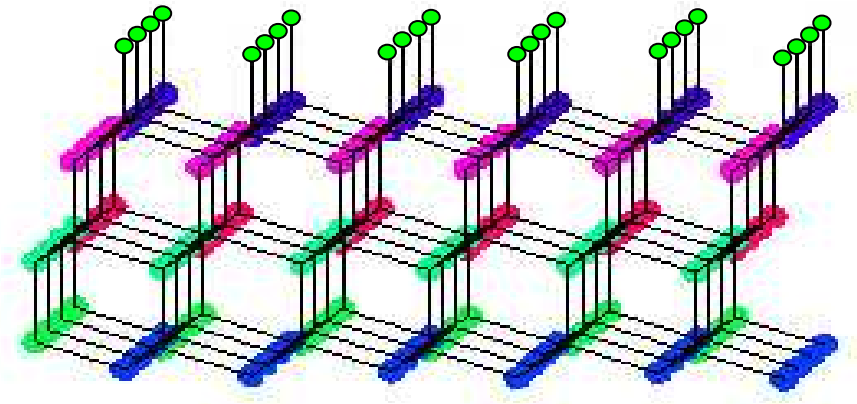

Fig.1 Part of the diamond substrate for CVD diamond film growth

Influence of [CH_3] on film deposition

Keep all the other parameters constant and set [CH_3] = 0.01%, 0.02% and 0.03%, respectively. The effect of [CH_3] on the film deposition rate is examined (see Fig. 2). This plot shows that the deposition rate of diamond film will increase if the [CH_3] is elevated. Since as the main growth CVD diamond film, increasing [CH_3] means the enhancing of the adsorption of CH_3 to the growth surface, which will definitely speed up the film deposition.

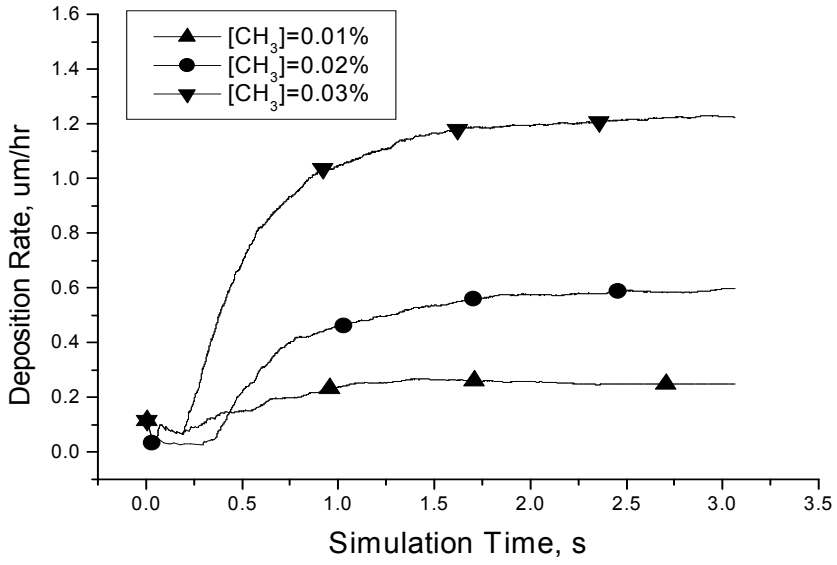

Fig. 2 Variation of deposition rate at different [CH_3] with deposition time

Influence of [H] on film deposition

Fig.3 shows the effect of [CH_3] on the film surface roughness. In the work, increasing the [CH_3] will make the film surface coarser. So from the simulation result, we can draw a conclusion: the higher the deposition rate, the coarser the diamond film, which is in good agreement with the prediction of reference [9].

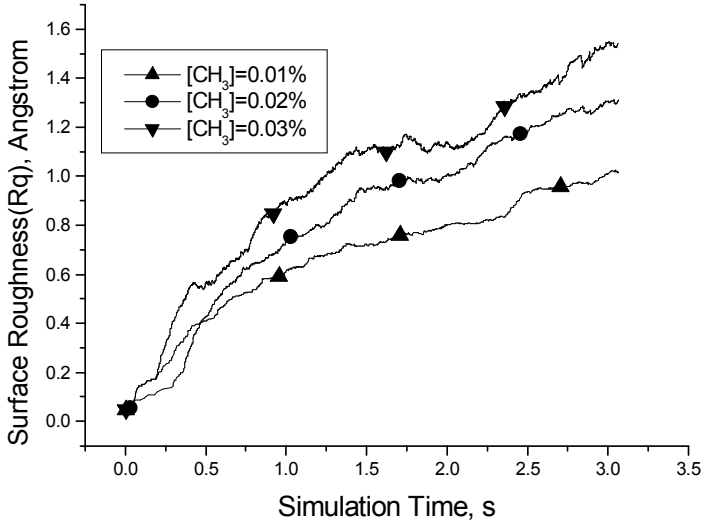

Fig. 3Variation of film surface roughness at different [CH3] with deposition time.

The influence of [CH_3] on the concentration of atom H embedded in film is shown in Fig. 4. Even though there is hardly the atom H embedded in the film in the first stage of the two-step model, however, the lower deposition rate in this stage limits its further application. From the second stage, we can find that the concentration of atom H embedded in the film increases with [CH_3]. This can be due to the indirect influence of [CH_3] on film deposition rate.

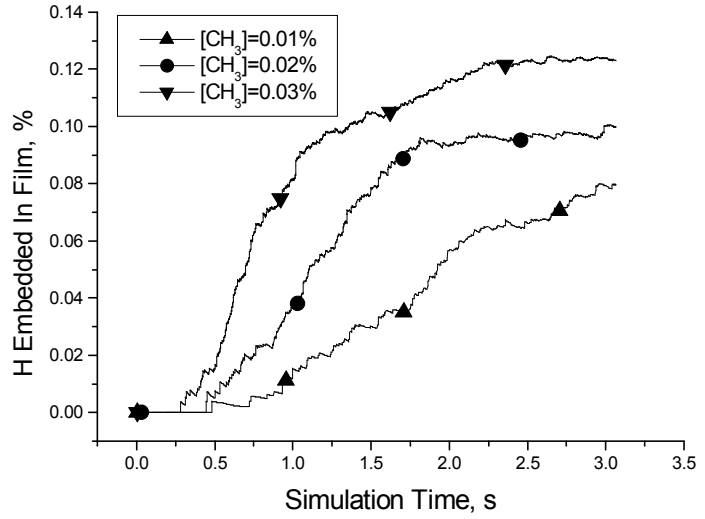

Fig. 4 Influences of [CH3] on the concentration of atom H embedded in film.

Keep all the other parameters constant and set [H] =0.01%, 0.05%, 0.1%, 0.2%, 0.3% and0.5%, respectively. The effect of [H] on film deposition rate is shown in Fig. 8. The deposition rate increases with [H] at first, then it decreases with the increasing [H]. Because too much atomic hydrogen causes unnecessarily strong abstraction, the formation of dimers will increase, which results in the deterioration of diamond film quality. So [H] =0.1% seems the optimal value in the present study. For each [H] value, the deposition rate of the new model is obviously higher than that of standard case.

Table 1 depicts the influences of [H] on film surface roughness and atom H embedded in film, respectively. It can be found that as the increasing of [H], the film becomes coarser. Even though when [H] equals to 0.02%, the film has smoother surface and less atom H embedded. However, its lower deposition rate at this [H] limits its further application. The variation tendency of Table 1 indicates that the concentration of atom H embedded in film is in proportional with the deposition rate.

Table 1 Influences of [H] on film deposition rate and surface roughness

H Concentration (%)	Deposition Rate(μ m/h)	Surface Roughness(Angstrom)
0.01	0.19	0.68
0.05	0.56	1.09
0.1	0.75	0.98
0.2	0.64	1.31
0.3	0.52	1.17
0.5	0.49	1.05

Conclusions

From the present simulation experiments of CVD diamond film growth, following conclusions can be drawn:

(1) The concentration of CH_3 can also influence the growth of CVD diamond film. The higher the concentration of CH_3, the faster the film growth, and the worse the film quality.

(2) Increasing the concentration of atom H can to some extent speed up film deposition rate, however, too much atom H on the contrary will hinder film grow and make the film coarser, therefore the concentration of atom H should be controlled to a constant value, in our simulation, 0.1% atom H is desirable.

Keywords: HTPB; Propellant; Relaxation; Master curve; Transformation relation

Abstract. The polymer-based propellant is a typical viscoelastic material. Better understanding of the relaxation properties of the propellant in the storage conditions is of great importance for predicting the lifetime. Due to the component complexity of the composite propellants, the transformation relation between the relaxation modulus and the complex modulus may not be suitable for all kinds of propellants. In the present work, we focused on the transformation of the relaxation modulus and complex modulus for the HTPB propellant. The master curves for the relaxation modulus and the storage modulus of the aged/unaged HTPB propellants were obtained by performing the stress relaxation tests and DMA tests, respectively. It was found that there existed a great difference in the double logarithmic plot between relaxation modulus and storage modulus master curves. Moreover, the testing results for the relaxation modulus and the storage modulus were well fitted by an empirical transformation relation with three segment-related coefficients. These three coefficients were determined by using the unaged samples, and then were applied to estimate the relaxation modulus of the aged samples. A good agreement between the calculation and the experimental results was also found, revealing that the three coefficients were insensitive to the aging time.

Introduction

The solid propellant based on the hydroxyl-terminated polybutadiene (HTPB) usually contains the ammonium perchlorate (AP), aluminum powder (Al) solids and additives, e.g. plasticizers. The combination of the polymer degradation due to the oxidizability of AP and the diffusion of the plasticizers in the storage condition may deteriorate the physical properties of the propellant [1,2]. The polymer-based propellant is a typical viscoelastic material. Therefore, better understanding of the relaxation properties of the propellant in the storage conditions is of great importance for predicting the lifetime. Two experimental methods, quasi-static extension and dynamic mechanical analysis (DMA), are commonly used to measure the relaxation properties of the viscoelastic materials [3-5]. The relaxation modulus in time domain and the complex modulus in frequency domain can be obtained by the two means, respectively. Compared with the time-consuming measurement for the relaxation modulus, the DMA testing for the complex modulus costs less time. It has been accepted that there exists a transformation relation between the relaxation modulus and the complex modulus [6]. Thus, the relaxation modulus may be easily estimated by conducting DMA tests based upon the transformation relation. Shen [4] presented an approximate relation between the storage modulus and relaxation modulus in terms of the HTPB propellants. However, there was a large deviation between the calculations and the test results when the expression was applied. Zhang [5] proposed a simplified transformation formula for the Nitrate Ester Plasticized Polyether (NEPE) propellant, and discussed the evaluation method for the NEPE aging under an assumption that there was a constant difference between the static relaxation modulus and the dynamic storage modulus. Due to the complexity of the composite propellants, the transformation formula may not be suitable for all kinds of propellants. In the present work, we focused on the transformation of the relaxation modulus and complex modulus for the HTPB propellants.

Relation of relaxation modulus to complex modulus

According to the linear theory of viscoelasticity, the transformation relation of the relaxation modulus $E(t)$ to the complex modulus $E(\omega)$ is expressed [6] as,

$$E'(\omega) = E_e + \omega\int_0^\infty \left[E(t) - E_e\right]\sin\omega t dt\,, \tag{1}$$

$$E''(\omega) = \omega\int_0^\infty \left[E(t) - E(\infty)\right]\cos\omega t dt\,, \tag{2}$$

where Ee is the equilibrium modulus; $E'(t)$ and $E''(t)$ are the dynamic storage modulus and loss modulus, respectively. Furthermore, one may get the following formulas by means of the Fourier transform, i.e.

$$E(t) = E_e + \frac{2}{\pi}\int_0^\infty \frac{1}{\omega}\left[E''(\omega)\right]\cos\omega t d\omega\,, \tag{3}$$

$$E(t) = E_e + \frac{2}{\pi}\int_0^\infty \frac{1}{\omega}\left[E'(\omega) - E_e\right]\sin\omega t d\omega\,. \tag{4}$$

Thus the static relaxation modulus $E(t)$ can be calculated if the complex modulus $E(\omega)$ is known. However, Eq.(3) and Eq.(4) are simple transformation relations mathematically. In practice, this set of relationships is not applicable so that some approximate transformation formulas are often used as follows [7],

$$E(t) = E'(\omega) - 0.4E''(0.4\omega) + 0.014E'(10\omega)|_{\omega=1/t}\,. \tag{5}$$

In view of the difference in the master curves between the storage modulus and the relaxation modulus for the HTPB propellant, Shen [4] proposed an exponential function of $a\exp[\pm(b\pm c\log t)]$ to modify the transformation relation. The approximate formula was then obtained as [4],

$$E(t) \approx 0.282\exp\left(-0.108 + 0.015\log t\right)E'(\omega)|_{\omega=1/t}\,. \tag{6}$$

It was found that the deviation cannot be neglected in some cases, which may attribute to the assumption that there was a constant difference in the master curves between the storage modulus and the relaxation modulus. In the present work, a term of $a+(b\log t/t_0)^c$ with three constants was incorporated into the transformation relation, and a segmented correction method was used to fit the measured curves.

Experimental

The aging experiments were performed in an oven with an electric heating oil bath, model DU-288. To evaluate the effects of aging on the relaxation properties, the samples were aged for 30 days at 50°C. The unidirectional tensile stress relaxation tests were conducted according to the Chinese Standard QJ 2487-1993 with an Instron Tester, Model 3365 at 70°C, 50°C, 20°C, 0°C, -20°C and -40°C. The initial strain was set to 5%. The acquisition time for the relaxation force is 2-1000s.

The dynamic complex modulus was measured by means of a commercial dynamic mechanical analyzer (TA Instruments, DMA Q800, USA), using rectangular specimens of about 35mm in length, 13mm width and 3mm thickness, and operated in the single cantilever mode. The scanning temperature ranges from -60°C to 60°C every 5°C at frequency of 1, 2, 4, 8, 16Hz.

Results and discussion

The relaxation modulus master curves of the aged/unaged HTPB propellants in the double logarithmic plot are shown in Fig.1. The storage modulus of the aged/unaged HTPB propellants at different frequencies was measured, and then the storage modulus master curves at the reference temperature of 20°C were obtained by performing the time-temperature superposition (TTS) procedure based on the principle of the equivalence of time and temperature, as shown in Fig.2, where a_T is a shift factor, T_s and T are the reference temperature and the test temperature, respectively.

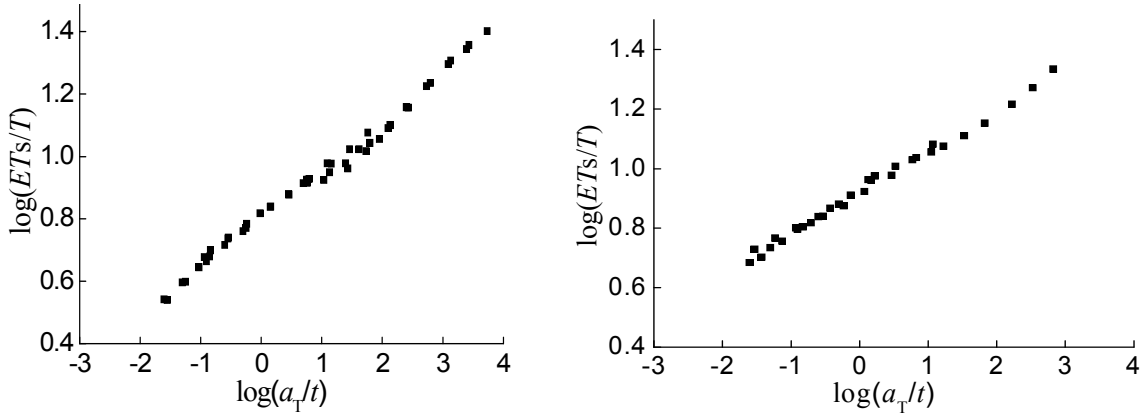

Fig. 1 The relaxation modulus master curves of unaged (Left) and aged (Right) propellants.

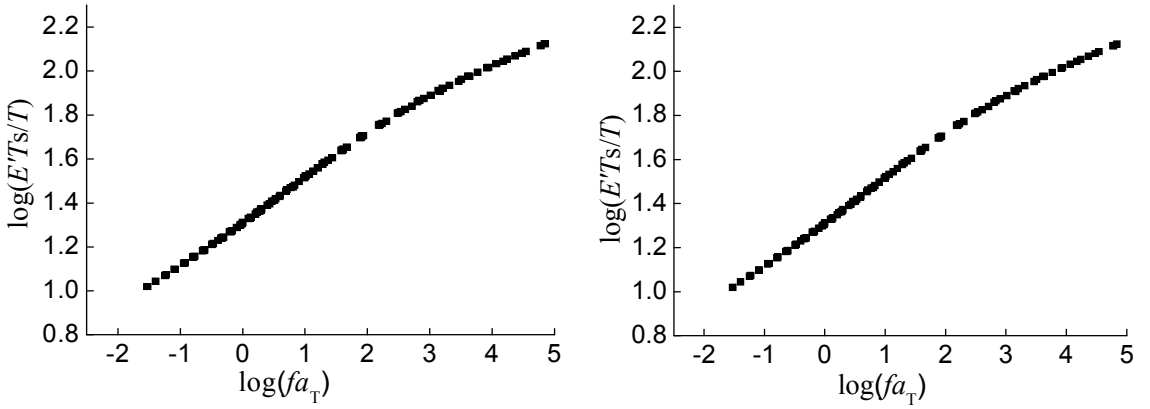

Fig. 2 The storage modulus master curves of unaged (Left) and aged (Right) propellants.

The same trends as reported by Ref.[4,5] were found for the relaxation modulus in time domain and for the storage modulus in frequency domain from Fig.1 and Fig.2. The relaxation modulus master curves differ from the storage modulus master curves in the vertical direction. In order to achieve a more reliable transformation relation of the relaxation modulus with the complex modulus, we shifted the storage modulus master curve downwards by a distance of d, and kept the relaxation modulus master curve and the storage modulus master curve to be located on the same beginning point, as illustrated in Fig.3.

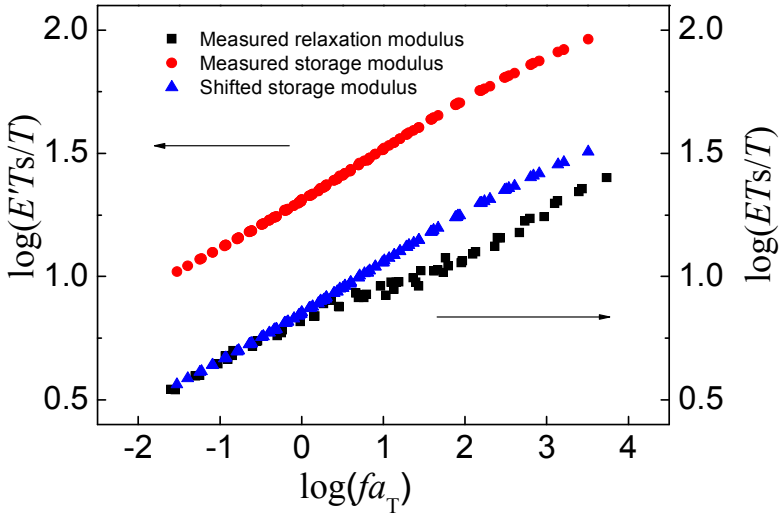

Fig. 3 The comparison to the master curves between the relaxation modulus and the storage modulus

By introducing the term of $a+(b\log t/t_0)^c$, the transformation relation becomes,

$$E(t)\approx\left[a+\left(b\log\frac{t}{t_0}\right)^c\right]E'(\omega)+d\,. \tag{7}$$

The three constants in the above formula were determined for the unaged HTPB propellants by a least square procedure over a three-segment fit. The three segments range -2-0, 0-2 and 2-4 in the horizontal axis of the master curve in Fig.4. The three coefficients *a*, *b* and *c* are different in three regions, as listed in Table 1. Therefore, three modified functions in the three segments can be reached easily. The constant *d* was determined by computing the vertical difference between the two master curves of the relaxation modulus and the storage modulus in Fig.4. The relaxation modulus calculated by using Eq.(7) was in agreement with the results measured by DMA, as indicated in Fig.4.

Table 1 The coefficients in three regions

$\log(f\,a_T)$	*a*	*b*	*c*
-2-0	1.106	-0.113	1.039
0-2	0.924	0.156	1.146
2-4	0.917	0.142	1.076

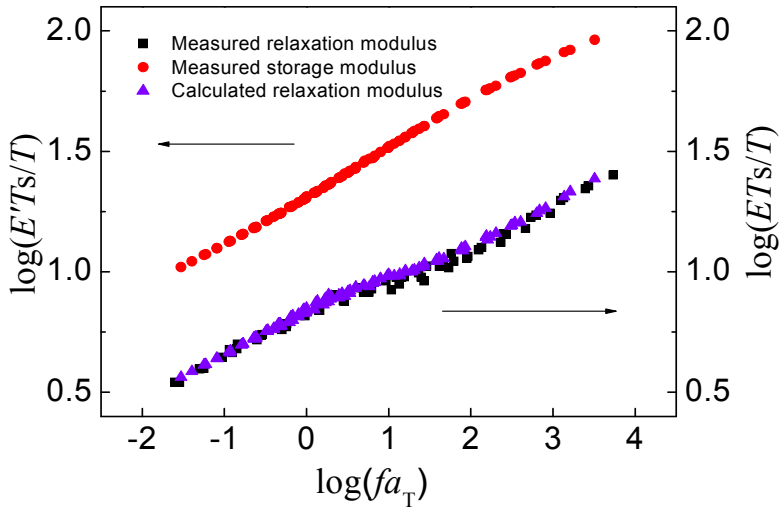

Fig. 4 The calculated relaxation modulus of unaged propellants and experimental data

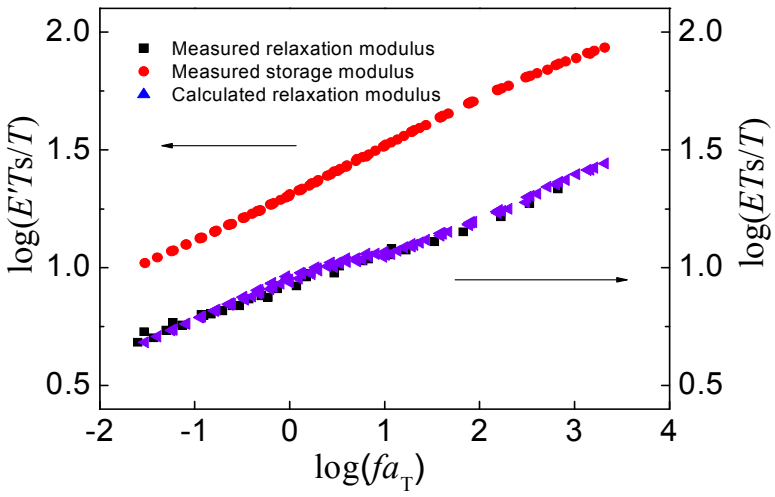

Fig. 5 The calculated relaxation modulus of aged propellants and experimental data

The three coefficients *a*, *b* and *c* were determined by using the unaged HTPB propellant samples, and then applied to Eq.(7) to estimate the relaxation modulus of the aged samples. A good agreement between the calculation and the experimental results was also found as shown in Fig.5, revealing that the three coefficients were insensitive to the aging time.

Conclusions

The master curves for the relaxation modulus and the storage modulus of the aged/unaged HTPB propellants were obtained by performing the stress relaxation tests and DMA tests, respectively. It was found that the relaxation modulus in time domain had the same trend as the storage modulus in frequency domain. There existed a great difference in the double logarithmic plot between the relaxation modulus and storage modulus master curves. Moreover, the testing results for the relaxation modulus and the storage modulus were well fitted by an empirical transformation relation with three segment-related coefficients. These three coefficients were determined by using the unaged samples, and then applied to estimate the relaxation modulus of the aged samples. A good agreement between the calculation and the experimental results was also found, revealing that the three coefficients were insensitive to the aging time.

Keywords: Steel fiber, surface pretreatment, interfacial bonding strength, pull-off test.

Abstract. For the characteristic that the mechanical properties of resin composite are lower than cast iron, steel fibers are used to improve its properties in this paper. A weak interfacial bonding strength between steel fibers and resin indicates that steel fibers' property cannot perform well in the polymer. In order to improve the interfacial bonding strength, four methods of surface treatment, phosphating, acid pickling, oxidation, and coupling are applied to steel fibers, and the corresponding pull-off tests are carried out to compare with untreated steel fibers. Research results show that the maximum interfacial bonding strength is increased by 45.1% after coupling treatment.

Introduction

With the development of engineering technology and increasing awareness of environment protection, some traditional metal materials are gradually replaced by advanced materials. Resin mineral composite is attractive due to its recyclability and easy process-ability and is superior in its good damping vibration attenuation and thermo stability, which is appropriate to manufacture basic parts of high-speed and precise machine tool, armarium, laser machinery[1,2], etc. However, the mechanical property of resin mineral composite is poor compared with cast iron, and fibers are considered to be used to improve its mechanical property. V.E. Yudin[3] and Hui Guo[4] studied the properties of carbon fiber reinforced resin composites and Ehsan Moaseri [5] used a microwave-assisted approach to enhance the interactions between carbon fiber and epoxy resin.

Resin matrix exhibits weak interfacial adhesion with most fibers due to low surface energy and chemically inert surfaces. Meng L [6] found that the maximal interlaminar shear strength and interface shear strength of carbon fiber/epoxy resin composite treated by supercritical water and hydrogen peroxide systems increased by 13.4% and 29.6% respectively compared with untreated carbon fibers. Hassan R M [7] and Abdel-Hamid M I [8] investigated the oxidation mechanism of chromic acid and found that oxidation treatment increased the number of function groups on the surface.

In this paper, four methods of surface treatment, phosphating, acid pickling, oxidation, and coupling are applied to steel fibers.

Experiments

Surface treatment methods

304 stainless steel fibers with average diameter of 0.2 mm were selected, and they were rinsed by ultrasonic cleaning for 15 minutes before surface treatment.

Phosphating treatment: The Phosphating reagent was mixed by 38.5% (v/v) phosphating liquid and 61.5% (v/v) H_2O. The fibers were immersed in the reagent at 45℃ for 8 minutes, and then dry in air.

Pickling treatment: A compounded pickling reagent, mixed by 15.3% (w/w) HNO_3, 2.0% (w/w) HF and 82.7% (w/w) H_2O, was used for test. The fibers were immersed in the reagent at 55℃ for 10 minutes, and then flush with water and dry in air.

Oxidation treatment: A chromic acid, mixed by 4.4% (w/w) $K_2Cr_2O_7$, 88.5% (w/w) H_2SO_4 and 7.1% (w/w) H_2O, was used for test. The fibers were immersed in the reagent at 70℃ for 5 minutes, and then flush with water and dry in air.

Coupling treatment: The coupling reagent was mixed by 59.1% (v/v) C_2H_5OH, 31.8% (v/v) H_2O and 9.1% (v/v) silane coupling agent. The pH value of the coupling reagent was kept between 4 and 6 by acetic acid. After 48h hydrolyzing at room temperature, the fibers were immersed in the reagent for 90-s then dry at 120℃ for 15 minutes.

Pull-off test of single steel fiber

The cylinder specimen is ø 14.4mm×8mm. The initial distance between clamps is 60mm and the speed is 1mm/min.

Results and discussion

Table 1 shows the results of pull-off tests of single steel before and after surface treatment, and Fig. 1 shows the average value of pull-off tests of single fiber.

Table 1 Maximum interfacial strength and residual strength of single steel fiber by different treatment methods

Treatment method	Maximum interfacial strength/residual strength(N)				
Untreated	32/10	26/12	34/12	32/12	40/14
Phosphating	36/20	30/14	34/18	28/18	36/20
Pickling	38/28	34/28	34/26	38/26	36/26
Oxidation	42/18	40/18	40/20	44/18	40/16
Coupling	46/16	46/14	58/24	44/16	44/16

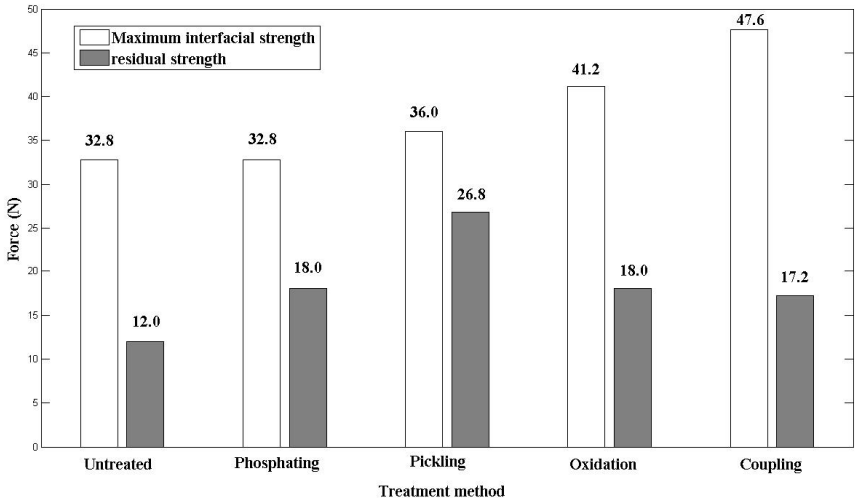

Fig. 1 Comparison of different maximum interfacial strength and residual strength of single steel fiber by different treatment methods

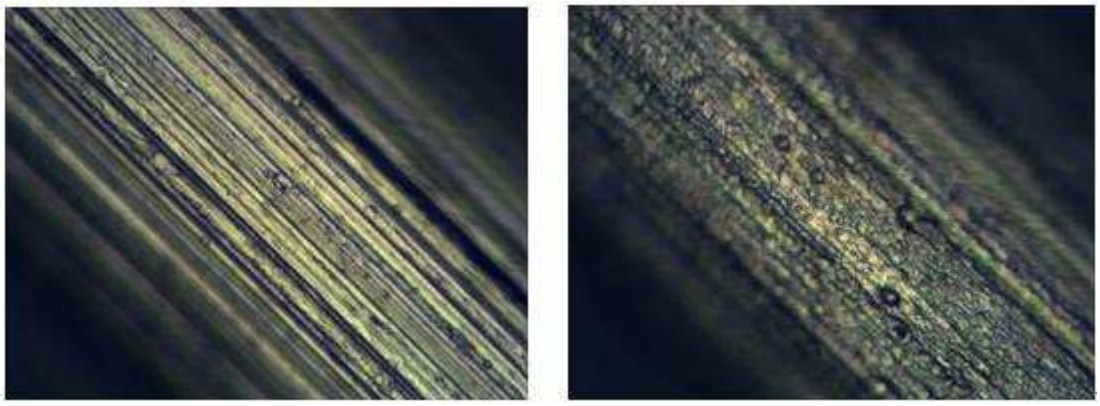
After phosphating treatment, a phosphating coating was added on the surface of steel fiber. The phosphating coating is composed of different phosphatic crystals, and tiny cracks exist among these phosphatic crystals [9]. These tiny cracks hinder fiber's pull-off from resin matrix after interfacial disbonding and cause the residual strength to increase.

The surfaces of steel fibers after pickling treatment were observed by microscope. Fig. 2 shows, corrosion pit spread all over the steel fiber surface while untreated fiber surface is smooth with shallow longitudinal grooves [8]. Fiber surface covered with corrosion pits increase the mechanical interlocking force with resin matrix, which result in a higher maximum interfacial strength and residual strength. Fig. 1 shows that the residual strength increases by 123% compared with untreated surface, and the maximum interfacial strength increases by 9.8%.



(a) (b)

Fig. 2 Microphotograph of steel fiber surface: (a) untreated, (b) pickling treatment.

Fig. 3 and Fig. 4 show the pull-test result of untreated and pickling single steel fiber, respectively.

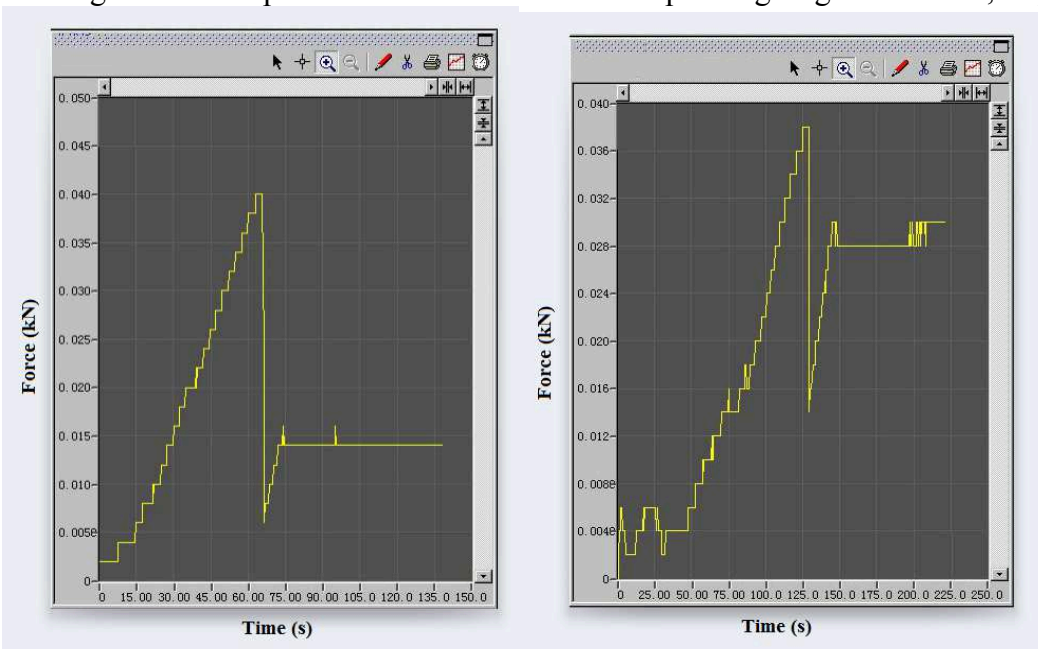


Fig. 3 Pull-off test result of untreated single steel fiber

Fig. 4 Pull-off test result of pickling single steel fiber

Oxidation treatment process uses chromium as intermediate product to trigger hydrolysis reaction on steel fiber surface, and further be oxidized into function groups. Fig. 1 shows, the maximum interfacial strength increases by 25.6%. This potentiation is mainly because oxidation treatment increases the number of function groups on steel fiber surface, such as hydroxyl groups and carboxyl groups [10]. The increasing function groups result in an increase of superficial wettability as well as surface free energy.

Fibers after coupling treatment perform the most considerable property among the four treatments, with 45.1% increase of the maximum interfacial strength. A strong chemical bonding is created between steel fiber surface and silane coupling agent, and silane coupling agent plays an important role in bridging between steel fiber and resin matrix [11, 12]. With the increase of reaction time, a strong interpenetrating layer has been formed, which increases the maximum interfacial strength between steel fiber and resin matrix.

Summary

Four different surface treatment methods are adopted to investigate the potentiation of interfacial bonding strength between steel fiber and resin. The following conclusions are derived from the experimental results.

The pull-off test of single steel fiber shows different degrees of increase in steel fiber's maximum interfacial strength compared with untreated steel fiber. Oxidation and coupling treatment perform a prominent increase of 25.6% and 45.1% respectively.

The residual strength improves obviously after all the four surface treatment, especially for the fibers after pickling, because the corrosion pits on fiber surface increase its mechanical interlocking force with resin matrix.

Abstract. In this research, Silver—nickel alloy nanocomposites has been synthesized by reducing mixture solution of Ni^{2+}, Ag^{+} with hydrazine hydrate as reducer and OP-10 as surfactant. Silver—nickel alloy nano-composites were characterized by FT-IR, XRD, SEM. And the electrochemical properties of the samples were studied by cyclic voltammetry. Ag-Ni/PANI composites were prepared by in-situ synthesis and emulsion polymerization, and the effect of conduction on the conductivity was investigated including content of alloy. The detailed analysis of the synthesis conditions shows that the reduction takes place in alkaline environment and low-temperature is propitious to generate alloy solid-solution grain. Composites prepared by emulsion polymerization in acidic aqueous solutions synthesis of polyaniline shows higher conductivity than pure polymer, due to the strong interaction between alloy particles and doping PANI.

Introduction

The range of properties of metallic systems can be greatly extended by taking mixtures of elements to generate intermetallic compounds and alloys [1]. In many cases, there is an enhancement in specific properties upon alloying, due to synergistic effects. The rich diversity of compositions, structures and properties of metallic alloys, has led to widespread applications in electronics, engineering and catalysis. The desire to fabricate materials with well defined, controllable, properties and structures, on the nanometre scale, coupled with the flexibility afforded by intermetallic materials, has generated interest in bimetallic alloy clusters, or ‘‘nanoalloys’’. Such clusters have been studied in colloidal solutions, in the solid state, on solid supports and in molecular beams [2-6].

Polyaniline is one of the most important conducting polymers (Trivedi, 1997). It is the first conducting polymer to be commercialized and now has applications ranging from batteries (Osama et al., 1992) to biosensors (Kim et al., 2000). Most polyaniline syntheses are carried out using aniline hydrochloride solution or a mixture of an aniline monomer and a dilute hydrochloride acid (Stejskal and Gelberg, 2002) [7-8]. Nowadays, composite materials give rise to numerous studies with a view to improving their mechanical, thermal, optical and other properties, which hold promise for novel technological applications.

Experimental

Preparation of nano-silver-nickel alloy. Ailver nitrate was obtained from Tianjin Xianshugu industrial park. Nickel sulfate was obtained from Tianjin chemical Regent Ltd. A quantity of silver nitrate and nickel sulfate solids were dissolved, and then mixed into a large beaker ultrasound. NaOH was added to adjust pH, and OP-10 was added as modifying agent. The mixture reactant was placed in 500ml three-necked flask, then hydrazine hydrate was added as reducing agent. Black powder was synthesized after been washed with distilled water, ethanol and acetone.

Preparation of nano-silver-nickel alloy/polyaniline composites. 50ml APS solution was added to a mixed solution of aniline hydrochloride and the microemulsion of nano silver-nickel alloy, then ultrasonic vibration 15 min. The solution was controlled to reaction at 0~5℃/4h. The reaction stopped, the solution was added large volume of acetone and washed several times with distilled water, ethanol and acetone.

The mixture was put into a vacuum oven at 50℃/24h.

Results and discussion

Silver-nickel alloy were determined by X-ray diffraction. Fig.1 showed characteristic peaks of 2θ = 38.08 °, 44.38 °, 51.8 °, 64.42 °, 77.4 ° and 81.5 °, the map contains all the characteristic peaks of silver and nickel. Silver nickel metal alloying has occurred compare with binary phase diagram of silver-nickel alloy. The peak of 2θ = 38.08 ° was larger than the corresponding peak of metal Ag, and the peak of 2θ = 44.38 ° was smaller than the corresponding peak of metal Ni, which showed that solids of Ag and Ni were mutual dissolved. Width phenomenon occurred on the XRD peak, the particle size of the sample smaller in alloying process. Figure 2 showed amorphous black sheet of nickel-silver alloy nanoparticles, and the average particle size about 50 nm.

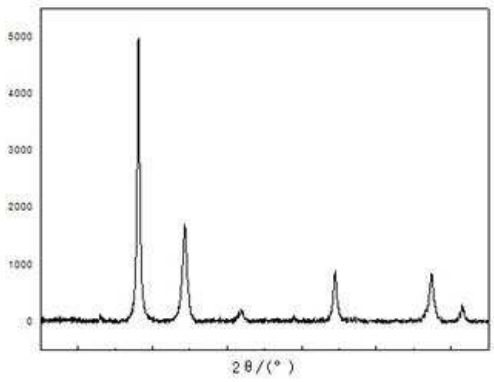

Fig. 1 XRD patterns of Ag-Ni particles

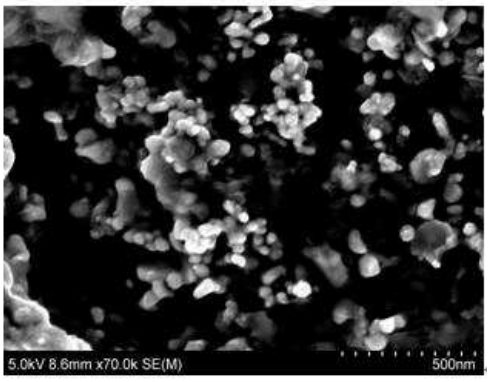

Fig. 2 SEM image of Ag-Ni alloy particles

Figure 3 showed XRD comparison chart of Ag-Ni alloy, Ag-Ni alloy/PANI composites and pure PANI. C showed the XRD patterns of pure nano-silver-nickel, the characterized peaks 2θ=38.08°, 44.38°, 51.8°, 64.42°, 77.4°, 81.5°; b showed the XRD patterns of pure polyaniline, the characterized peaks around 2θ=25°, and the strength relative weak; a showed the XRD patterns of nano-silver-nickel alloy/polyaniline composites, it can be seen that the eristic lines containing both all the diffraction peaks of silver-nickel and a wide area of the characteristic diffraction peaks of polyaniline. It showed that nano-silver-nickel alloy particles were contained in the composite materials.

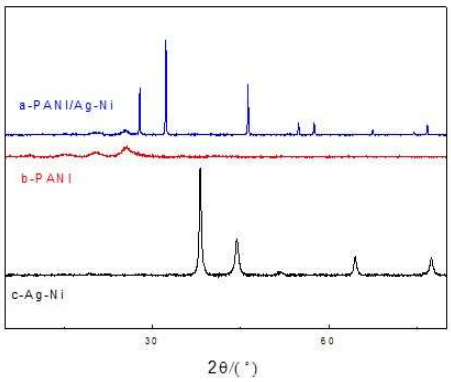

Fig. 3 XRD patterns of (a) Ag-Ni alloys (b) Ag-Ni/PANI composites (containing 25 wt % Ag-Ni alloys) (c) neat PANI

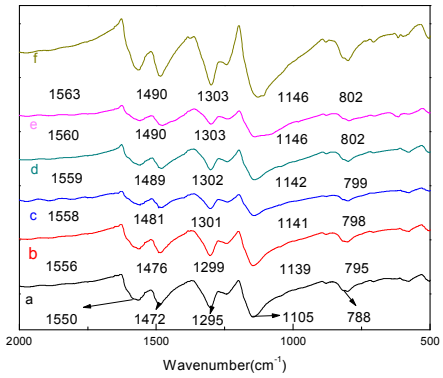

Fig. 4 FT-IR spectra of prepared with different Ag-Ni/PANI ratios(wt%) a) 0, (b) 5; (c) 10; (d) 15; (e) 20; (f) 25

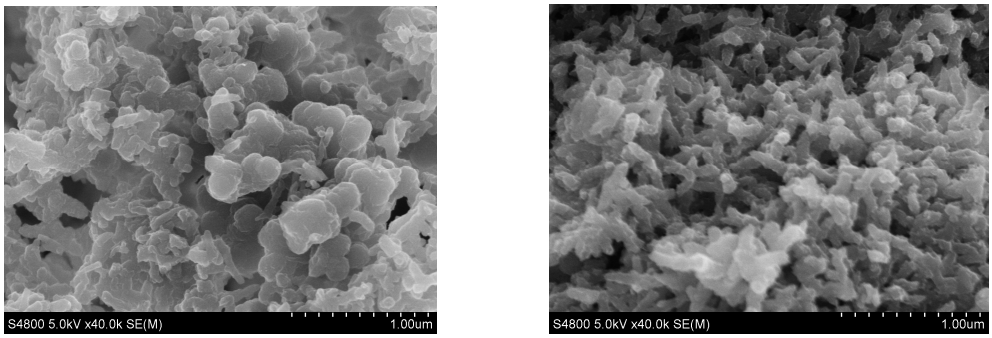
Figure 4 showed the FTIR map of the different content of nano-silver-nickel alloy polyaniline nanocomposites. The contrast pattern can be clearly seen that the spectra of Ag-Ni/PANI and polyaniline were similar, which can be seen the surface of nano-alloy particles wrapped polyaniline. The characteristic peaks showed that the absorption peak of the composite material increased with the nano-metal content increased. Infrared absorption was occurred blue shift, which indicated that the strong chemical interactions existed between the nano-alloy and polyaniline.



(a) (b)

Fig. 5 SEM of neat PANI (a) and the Ag-Ni/PANI composites (b)

Figure 5(a) showed the amorphous sheet of pure PANI, and the particle size distribution in the 0.1 μm-0.5 μm. Figure 5(b) showed the SEM photograph of nano-Ag-Ni alloy / PANI composites, it can be seen, PANI and nano-alloy composites particles from the amorphous sheet into rod, particle size about 0.1 μm, and about 4-8 μm in length. The SEM photograph and XRD analysis showed that the composite structure of the nano silver-nickel alloy particles were wrapped by PANI, the particles increase, and orderly rod, which was due to the polyaniline and nano alloys particles were bonded, the of nano-alloy particles were hinded agglomeration by the PANI adsorbed on the surface.

Keywords: Thiophene; Liquid Crystal; Synthesis; Phase Behavior

Abstract. The synthesis of a new liquid crystal thiophene monomer of (*E*)-4-(6-(3-(thiophen-3-yl)-acryloyloxy)hexyloxy)biphenyl-4'-ethylbenzoate (LC-M) is presented. The chemical structure of this monomer and intermediate compounds was characterized by FT-IR and ^{1}H-NMR. The phase behavior was investigated by polarizing optical microscopy and differential scanning calorimetry. LC-M showed nematic threaded and schlieren textures on heating and cooling cycles.

Introduction

In recent year, the organic conjugated materials have attracted more and more interest due to their excellent electrical and optoelectric properties [1-3], and many important potential applications in various areas such as organic thin-film transistors [4], solar cells [5], organic light-emitting diodes [6], sensor arrays [7], large-area plastic displays [8], and power transmission devices [9]. Today, the thiophene derivatives occupy an important position in the study of the organic conjugated materials. Functionalized thiophenes based molecules are being shown to be the potential candidates for high end applications [10] [11]. From a scientific and industrial point of view, the liquid crystalline (LC) thiophene derivatives are fascinating because they combine the electrical properties of thiophene with the optical properties of conventional LC materials. These properties are expected to be controllable through the spontaneous orientation of mesogenic group in side chain to enhance the main chain thiophene coplanarity.

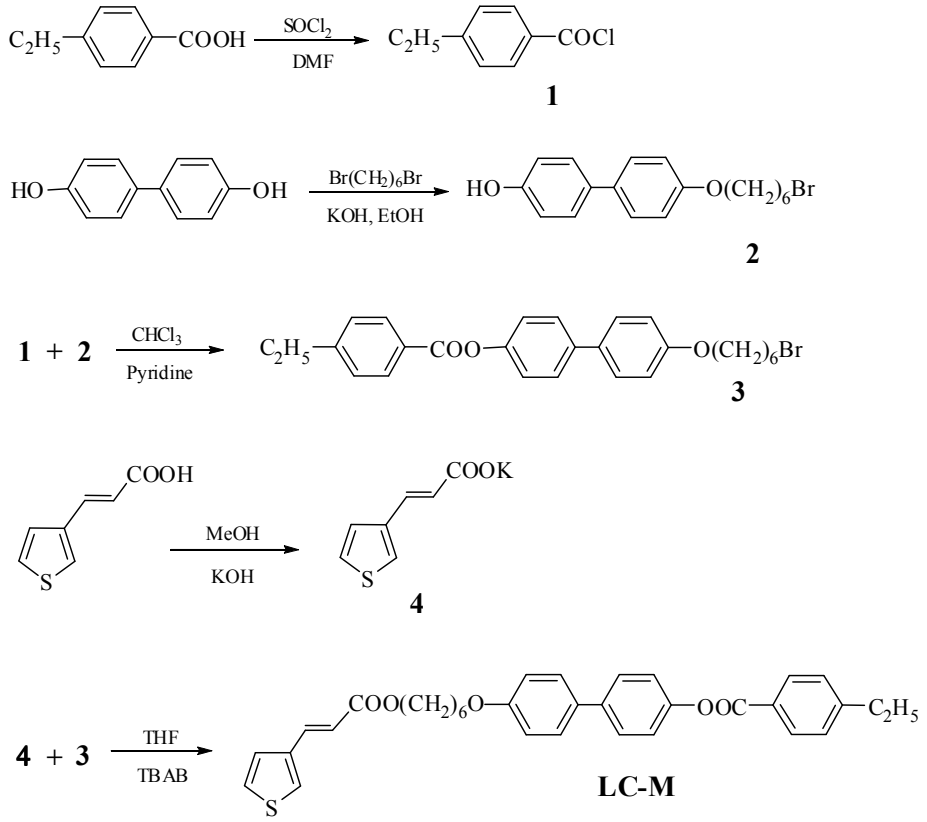
In this study, a new nematic thiophene monomer containing long flexible spacer length between thiophene and mesogenic unit was prepared and characterized. The phase behavior was investigated with polarizing optical microscopy (POM) and differential scanning calorimetry (DSC).

Experimental

Materials. All chemicals were obtained from the indicated sources and used as received. 4-Ethylbenzoic acid (Beijing, China), 1,6-dibromohexane (Shenyang, China), and 4,4′-dihydroxybiphenyl (Sigma-Aldrich) were used as received. Potassium (*E*)-3-(thiophen-3-yl)acrylate were obtained from Chemistry Laboratory Center in Northeastern University of China. All other solvents and reagents used were purified by standard methods.

Measurements. FT-IR spectra were measured on a PerkinElmer spectrum One (B) spectrometer (PerkinElmer, Foster City, CA). ^{1}H-NMR spectra were obtained using a Bruker Avance 400 (Bruker, Swiss) high resolution NMR spectrometer, and chemical shifts were reported in ppm with tetramethylsilane (TMS) as an internal standard. The characteristic optical textures were observed with a Leica DMRX POM (Leica, Germany) equipped with a Linkam THMSE-600 (Linkam, United Kingdom) cool and hot stage. The thermal properties were determined with a Netzsch DSC 204 (Netzsch, Hanau, Germany) equipped with a cooling system at a heating and cooling rates of 10^{o}C/min in a nitrogen atmosphere.

Synthesis of liquid crystal thiophene monomer. The typical synthetic route of the thiophene monomer is outlined in Scheme 1.



Scheme 1 Synthetic route of LC-M

4-(6-bromohexyloxy)biphenyl-4'-ol (2). 4-(6-Bromohexyloxy)biphenyl-4'-ol (2) was prepared according to the method reported by Hu and coworkers [12]. Yield: 63%, mp: 133°C. IR (KBr, cm^{-1}): 3388 (–OH); 2933, 2860 ($-CH_2-$); 1611, 1501 (Ar–), 1247 (C–O–C); 515 (C–Br). ^{1}H-NMR (δ, ppm from TMS in $CDCl_3$): 1.28–1.87 [m, 8H, $-OCH_2(C\underline{H}_2)_4CH_2Br$], 3.58 (t, 2H, $-C\underline{H}_2Br$), 4.14 [t, 2H, $-OC\underline{H}_2-$], 6.89–7.70 (m, 8H, Ar–H), 9.45 (s, 1H, –OH).

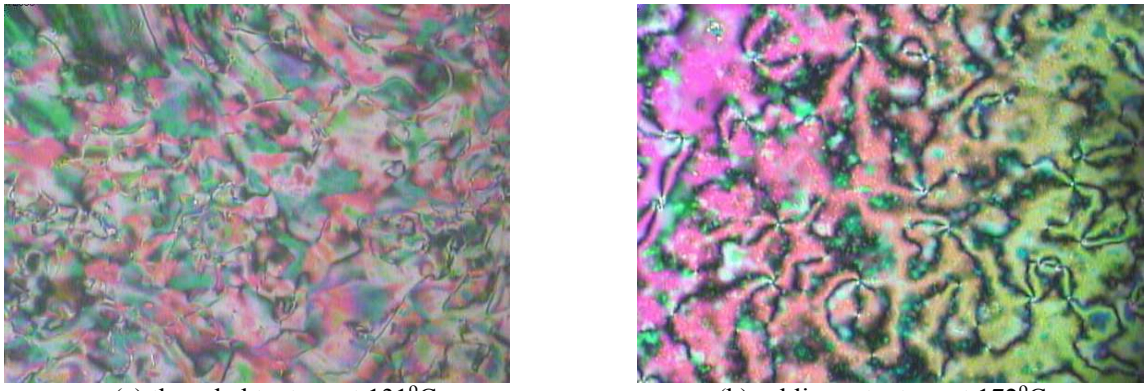
4-(6-bromohexyloxy)biphenyl-4'-ethylbenzoate (3). The compound **1** (8.4g, 0.05mol), dissolved in 10mL of chloroform, was added dropwise to a stirred solution of the compound **2** (17.4g, 0.05mol) in 250mL of chloroform and 8mL of dry pyridine. The reaction mixture was stirred at room temperature for 2h, and followed by refluxing at 65°C for 24h. The resulting mixture was cooled to ambient temperature. After evaporation of the solvent under reduced pressure, the crude product was precipitated by adding methanol to the residue and recrystallized with ethanol/acetone (1:1). Solid **3** was obtained. Yield: 65%, mp: 124°C. IR (KBr, cm^{-1}): 2977, 2856 ($-CH_2-$, $-CH_3$); 1727 (C=O); 1605, 1496 (Ar–), 1257 (C–O–C); 519 (C–Br). ^{1}H-NMR (δ, ppm from TMS in $CDCl_3$): 1.30 (t, 3H, $-C\underline{H}_3$), 1.37–1.85 [m, 8H, $-CH_2(C\underline{H}_2)_4CH_2-$], 2.71 (m, 2H, $-C\underline{H}_2CH_3$), 3.57 (t, 2H, $BrC\underline{H}_2-$), 4.15 [t, 2H, $-(CH_2)_5C\underline{H}_2O-$), 7.01–8.18 (m, 12H in aromatic).

(E)-4-(6-(3-(Thiophen-3-yl)acryloyloxy)hexyloxy)biphenyl-4'-ethylbenzoate (LC-M). The compound **3** (4.8g, 0.01mol), potassium (*E*)-3-(thiophen-3-yl)acrylate (1.92g, 0.01mol), and tetrabutyl ammonium bromide (0.2g) were dissolved in 200mL of dry tetrahydrofuran (THF). The reaction mixture was stirred for 48 h at 60°C under nitrogen conditions. The resulting solution was filtered. After THF was removed by evaporation, the residue was poured into 150mL of cold water, and the precipitate was filtered. The crude product was washed several times with water, recrystallized from acetone, and purified by column chromatography (silica gel, dichloromethane). Yield: 76%. mp: 94°C. IR (KBr, cm^{-1}): 2927, 2856 ($-CH_2-$, $-CH_3$); 1728, 1711 (C=O); 1635(C=C); 1605, 1495 (Ar–), 1257 (C–O–C and C-S). ^{1}H-NMR (δ, ppm from TMS in $CDCl_3$): 1.31 (t, 3H, $-C\underline{H}_3$), 1.56–1.86 [m, 8H, $-CH_2(C\underline{H}_2)_4CH_2-$], 2.71 (m, 2H, $-C\underline{H}_2CH_3$), 4.04 (t, 2H, $-COOC\underline{H}_2-$),

4.16 [t, 2H, −$(CH_2)_5C\underline{H}_2O$−), 6.29 (d, 1H, −C<u>H</u>=CHCOO−), 7.69 (d, 1H, −CH=C<u>H</u>COO−), 6.99–8.18 (m, 15H in thiophene and aromatic).

Results and discussion

Optical textures. The optical textures of the thiophene monomer LC-M were observed by POM with hot stage. The visual observations under POM showed that LC-M revealed enantiotropic nematic phase on heating and cooling cycles. When LC-M was heated to 90°C, the sample melted and the threaded texture gradually appeared, and the texture disappeared at 178°C. Cooling isotropic state, the schlieren texture slowly appeared at 178°C, and crystallized at 67°C. Optical textures of LC-M are shown in Figure 1 (a) and (b).



(a) threaded texture at 131°C (b) schlieren texture at 172°C

Fig.1. Optical textures of LC-M (200×)

Thermal properties. The thermal properties of LC-M were investigated with DSC. The DSC curves, obtained on the second heating and cooling scans, are shown in Figure 2.

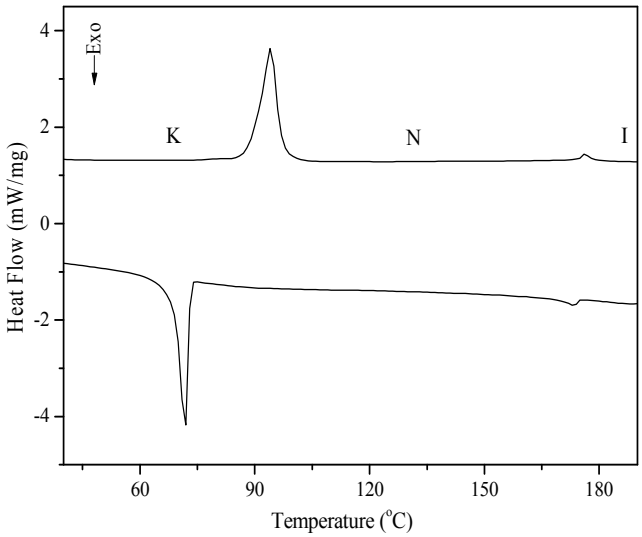


Fig.2. DSC curves of LC-M

DSC heating curve of LC-M showed a melting transition at 94.2°C and a nematic to isotropic phase transition at 176.2°C. The mesophase temperature range was 82°C. On cooling, two exothermic peaks were seen, which represent an isotropic to nematic phase transition at 173.4°C, a nematic to crystallization transition at 71.7°C. All phase transitions were reversible and did not change on repeated heating and cooling cycles, the phase transition temperatures noted in DSC curves were in agreement with the phase transition temperatures observed by POM.

Conclusion

We reported a new thiophene monomer as nematic liquid crystal. LC-M exhibited the threaded texture and schlieren texture of a nematic phase. Its melting temperature and isotropic or clearing temperature were 94.2^{o}C and 176.2^{o}C, respectively. The mesophase temperature range was 82^{o}C.

Keywords: asphalt; emulsifier; nonylphenol polyoxyethylene ether; synthesis; online FTIR

Abstract. A novel cationic asphalt emulsifier of N-(3-polyoxyethylene nonyl phenyl ether (10)-2-hydroxyl) propyl-N,N,N- triethyl ammonium chloride was synthesized by nonylphenol polyoxyethylene ether (NP-10), epichlorohydrin and triethylamine. The optimum reaction condition was obtained. The yield reaches 48.72% at the optimum conditions of the feedstock mole ratio of NaOH to NP-10 1.0, the mole ratio of epichlorohydrin to NP-10 1.2, the mole ratio of triethylamine to NP-10 1.2, reaction temperature 70℃, and reaction time 8 h. The structure of the emulsifier was identified by FTIR. The synthesis process was monitored by online FTIR technique and the intermediate was detected. Based upon the experimental data, a plausible reaction mechanism was proposed for the reaction. The emulsifier belongs to slow-set asphalt emulsifier.

Introduction

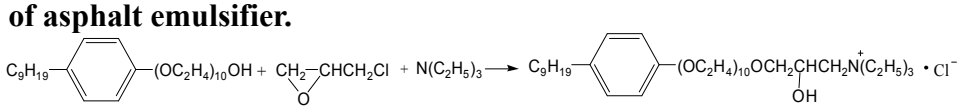
Asphalt emulsifier is divided into cationic, anionic, nonionic and amphoteric according to the different charges [1,2]. Negm [3] synthesized a series of cationic surfactants with benzaldehyde, p-aminopyridine, xylene, 1,2-dibromoethane, 1,6-dibromohexane and 1,12-dibromododecane. Two kinds of Gemini cationic asphalt emulsifier were synthesized by the reaction of octadecyl amine, octadecyldimethyl tertiary amine and epichlorohydrin[4]. Li [5] synthesized an asymmetric Gemini cationic surfactants, characterized its structure and discussed the affect factors of stability. Banno [6] synthesized novel cationic surfactants which have biodegradability and chemical recyclability green sustainable. Slow-set asphalt emulsifier is a key material for slurry seal [7,8].

In previous papers, we have synthesized different kinds of asphalt emulsifiers [4,9,10]. A novel cationic asphalt emulsifier was synthesized in this paper. The synthesis process was monitored by online FTIR technique and the intermediate was detected. Based upon the experimental data, a plausible reaction mechanism was proposed for the reaction.

Experimental

Materials. Nonylphenol polyoxyethylene ether was technical grade and obtained from Nanjing Gutian Chemical Co., Ltd, Nanjing, China. All the other reagents were of analytical reagent grade and used without further purification. The asphalt used was AH-90, which was provided by Shengli Refinery of Qilu Petrochemical Company, Zibo, China. The mineral aggregate was the mixture of different size of marble stone.

Synthesis of asphalt emulsifier.



(R1)

NP-10 (66.0 g, 0.1 mol), NaOH (4.0 g, 0.1 mol) and 30 mL isopropanol were added in a three-necked flask. Epichlorohydrin (11.10 g, 0.12 mol) was added dropwise. Triethylamine (12.15 g, 0.12 mol) was added dropwise and stirred for 8 h at 70℃ in a water bath.

The yield of product. The yield (Y_1) of product was measured by bromophenol blue two-phase titration method. 2.0000 g sample was weighted and dissolved in distilled water, and transferred to a 100 mL volumetric flask. Then, 10mL of the sample solution was measured by a pipette and placed

in a stoppered graduated cylinder. 1mL 10% sodium carbonate solution and 0.2 mL of bromophenol blue indicator were added. The stoppered graduated cylinder was shaken well. Then 10 mL 1,2-dichloroethane was added. The mixed solution was titrated with standard sodium dodecyl sulfate solution. The endpoint of the titration was identified as the blue color of lower solvent phase completely disappeared.

$$Y_1 = \frac{C \times V_1 \times 10^{-3} \times 10}{n \times m_1} \times m \times 100\%$$

where, Y_1—means the yield of product, %.

V_1—means the consumed volume of sodium dodecyl sulfate standard solution, mL.

C—means the concentration of sodium dodecyl sulfate standard solution, mol/L.

m—means the total mass of sample, gram.

m_1—means the mass of sample to be titrated, gram.

n—means the mole of NP-10, mol.

FTIR analysis. FTIR spectra were recorded from 400 to 4000 cm^{-1} wavenumber range with averaging 32 scans at a resolution of 4 cm^{-1} on a Bruker Tensor-27 FTIR spectrophotometer.

Online FTIR analysis. The online FTIR analysis was performed on a ReactIR 4000 spectrophotometer (Mettler-Toledo AutoChem, Inc., USA). FTIR spectra were recorded from 650 to 4000 cm^{-1} wavenumber range at a resolution of 8 cm^{-1}. NP-10 (66.0 g, 0.10 mol), NaOH (4 g, 0.1 mol) and 160 ml isopropanol were added in a three-necked flask. The solution was stirred and heated to 70℃ in a water bath. The detector of the online FTIR analysis system was immersed in the solution during the reaction to record the 3D online FTIR spectra. Epichlorohydrin (11.10 g, 0.12 mol) was added dropwise after 8 min. Triethylamine (12.15 g, 0.12 mol) was added dropwise after 15 min. The magnetic stirrer was under operation during the online FTIR measurement.

Preparation of bituminous emulsion.12.5 g emulsifier of product was dissolved in 200 mL water. The pH value was adjusted to 2.0 by adding hydrochloric acid, then the solution was heated to 60℃. 300 g AH-90 asphalt was heated to 120℃. The bituminous emulsion was prepared by mixing the aqueous solution containing emulsifier and asphalt in a colloid mill for 1 min.

Mixing experiment. Mineral aggregate (100 g), cement (1 g) and water (8 g) were mixed. Bituminous emulsion (10 g) was then added, and the mixture was stirred at 60 revolutions per minute. The mixing time was recorded by observation of the mixing performance.

Results and discussion

Synthesis route optimization

Reaction time. The reaction conditions were as follows: reaction temperature 70℃, the mole ratio of NaOH to NP-10 1.0, the mole ratio of epichlorohydrin to NP-10 1.2, the mole ratio of triethylamine to NP-10 1.2. Figure 1 represents the yield (Y_1) of product versus reaction time. As shown in Fig. 1, the yield increases with the reaction time, and levels off after 8 h. Therefore, the optimum reaction time is 8 h.

Reaction temperature. The reaction conditions were as follows: reaction time 8 h, the mole ratio of NaOH to NP-10 1.0, the mole ratio of epichlorohydrin to NP-10 1.2, the mole ratio of triethylamine to NP-10 1.2. Figure 2 represents the yield versus reaction temperature. As shown in Fig. 2, the yield increases with reaction temperature, and levels off after 70℃. Therefore, the optimum reaction temperature is 70℃.

The dosage of NaOH. The reaction conditions were as follows: reaction temperature 70℃, reaction time 8 h, the mole ratio of epichlorohydrin to NP-10 1.2, the mole ratio of triethylamine to NP-10 1.2. Figure 3 represents the yield versus the mole ratio (m) of NaOH to NP-10. As shown in Fig. 3, the yield increases with the mole ratio (m) of NaOH to NP-10, and levels off after 1.0. Therefore, the optimum the mole ratio (m) of NaOH to NP-10 is 1.0.

The mole ratio of epichlorohydrin to NP-10. The reaction conditions were as follows: reaction temperature 70℃, reaction time 8 h, the mole ratio of NaOH to NP-10 1.0, the mole ratio of

triethylamine to NP-10 1.2. Figure 4 represents the yield versus the mole ratio (n) of epichlorohydrin to NP-10. As shown in Fig. 4, the yield increases with the mole ratio (n), and levels off after 1.2. Therefore, the optimum the mole ratio (n) of epichlorohydrin to NP-10 is 1.2.

The mole ratio of triethylamine to NP-10. The reaction conditions were as follows: reaction temperature 70℃, reaction time 8 h, the mole ratio of NaOH to NP-10 1.0, the mole ratio of epichlorohydrin to NP-10 1.2. Figure 5 represents the yield versus the mole ratio (r) of triethylamine to NP-10. As shown in Fig. 5, the yield increases with the mole ratio (r), and levels off after 1.2. Therefore, the optimum the mole ratio (r) of triethylamine to NP-10 is 1.2.

Overall speaking, the optimum reaction conditions are as below: reaction temperature 70℃, reaction time 8 h, the mole ratio of NaOH to NP-10 1.0, the mole ratio of epichlorohydrin to NP-10 1.2, the mole ratio of triethylamine to NP-10 1.2. The yield reaches 48.72% at the optimum reaction conditions.

FTIR characterization. In the FTIR spectrum of product, the absorption at 3404 cm^{-1} is assigned to the O-H stretching. The absorption at 3050 cm^{-1} is assigned to the C-H stretching, which is attributed to benzene. The absorption at 1604 cm^{-1}, 1578 cm^{-1}, 1505 cm^{-1} and 1460 cm^{-1} are assigned to benzene skeleton vibration. The absorptions at 1348 cm^{-1} is assigned to O-H out-plane bending vibration. The absorption at 1250 cm^{-1} is assigned to Ar-O-C asymmetrical stretching vibration. The absorption at 1184 cm^{-1} is assigned to C-N stretching. The absorption at 1106 cm^{-1} is assigned to C-O stretching. The absorption at 949 cm^{-1} is assigned to O-H out-plane bending vibration. Therefore, the FTIR spectrum agrees with the chemical structure of the target product.

Online FTIR Analysis. The reaction was monitored by online FTIR technique. Five components were detected automatically during the online FTIR analysis. Its FTIR spectra were obtained. In the

FTIR spectrum of component 1, the absorptions at 1654 cm^{-1}, 1543 cm^{-1}, 1505 cm^{-1} are assigned to benzene skeleton vibration. The absorption at 1316 cm^{-1} is assigned to O-H plane bending vibration. The absorption at 1250 cm^{-1} is assigned to Ar-O-C asymmetrical stretching vibration. The absorption at 1108 cm^{-1} is assigned to C-OH stretching. The absorption at 1067 cm^{-1} is assigned to C-O-C stretching. The absorption at 952 cm^{-1} is assigned to vibration in ring. The absorption at 679 cm^{-1} is assigned to C-Cl stretching. Therefore, component 1 obtained by online FTIR should be the intermediate 1 as shown in Scheme 1.

In the FTIR spectrum of component 2, the absorptions at 1654 cm^{-1} and 1505 cm^{-1} are assigned to benzene skeleton vibration. The absorptions at 1292 cm^{-1} and 1049 cm^{-1} are assigned to Ar-O-C stretching vibration. The absorptions at 1257 cm^{-1}, 950 cm^{-1} and 793 cm^{-1} are assigned to epoxy C-O stretching vibration. The absorption at 1148 cm^{-1} is assigned to C-O-C stretching. The absorption at 732 cm^{-1} is assigned to methylene plane swing vibration. Therefore, component 2 obtained by online FTIR should be the intermediate 2 as shown in Scheme 1.

In the FTIR spectrum of component 3, the absorption at 1349 cm^{-1} is assigned to O-H plane bending vibration. The absorptions at 1266 cm^{-1} and 1063 cm^{-1} are assigned to Ar-O-C stretching vibration. The absorption at 1086 cm^{-1} is assigned to C-OH stretching. The absorption at 949 cm^{-1} is assigned to vibration in ring. The absorption at 852 cm^{-1} is assigned to C-Cl stretching. Therefore, component 3 agrees with the chemical structure of the target product.

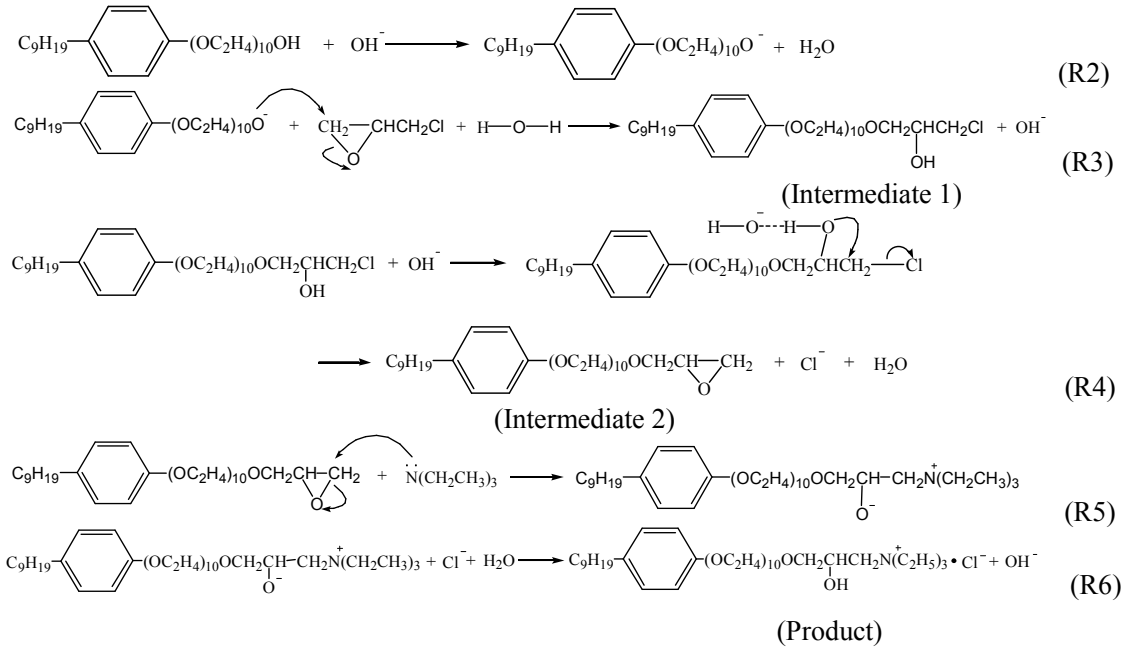
In the FTIR spectrum of component 4, the absorptions at 1245 cm^{-1} and 952 cm^{-1} are assigned to epoxy C-O stretching vibration. The absorption at 1124 cm^{-1} is assigned to C-O-C stretching. The absorption at 816 cm^{-1} is assigned to C-Cl stretching. Therefore, component 4 obtained by online FTIR agrees with the chemical structure of epichlorohydrin.

In the FTIR spectrum of component 5, the absorptions at 1650 cm^{-1}, 1558 cm^{-1} and 1506 cm^{-1} are assigned to benzene skeleton vibration. The absorption at 1314 cm^{-1} is assigned to O-H plane bending vibration. The absorptions at 1269 cm^{-1} and 1065 cm^{-1} are assigned to Ar-O-C asymmetric stretching vibration. The absorption at 1160 cm^{-1} is assigned to C-O-C stretching. The absorption at 1108 cm^{-1} is assigned to C-OH stretching. The absorption at 947 cm^{-1} is assigned to vibration in benzene ring. Therefore, the spectrum of component 5 agrees with the chemical structure of NP-10.

Figure 6 gives the relative concentration (c) of component 1-5 versus reaction time. As shown in Fig. 6, the relative concentration of component 1 increases slightly with reaction time. Therefore, we can ascertain that component 1 should be the intermediate 1 as shown in Scheme 1 according to the changing trend of concentration and the online FTIR spectrum.

The relative concentration of component 2 increases gradually with reaction time. Then the relative concentration of component 2 keeps constant. Finally the relative concentration of component 2 decreases slightly. Therefore, we can ascertain that component 2 should be the intermediate 2 as shown in Scheme 1 according to the changing trend of concentration and the online FTIR spectrum. The relative concentration of component 3 increases on the whole. Therefore, we can ascertain that component 3 should be the product according to the changing trend of concentration and the online FTIR spectrum. The relative concentration of component 4 decreases gradually with reaction time, then keeps constant. Therefore, we can ascertain that component 4 should be epichlorohydrin according to the changing trend of concentration and the online FTIR spectrum. The relative concentration of component 5 decreases gradually with reaction time. Therefore, we can ascertain that component 5 should be NP-10 according to the changing trend of concentration and the online FTIR spectrum.

Synthesis reaction mechanism. For reaction (R1), we proposed a Scheme 1 as shown in reactions (R2-R6), based upon the spectra obtained by online FTIR and the concentration changing trends of the five components in Fig. 6. Alcohol anion is formed by ionization from NP-10 in alkaline condition (reaction R2). The alcohol anion is a strong nucleophile, and attacks the less substituted carbon atom of epichlorohydrin in an S_N2 reaction (reaction R3). The intermediate 1 is formed. The intermediate 2 is obtained by the cyclization reaction of intermediate 1 (reaction R4). Triethylamine has strong nucleophilicity. Then, the product is formed by triethylamine attacking the less substituted carbon atoms of epoxy group (reaction R5-R6).



Scheme 1 Synthesis reaction mechanism

Mixing performance. The emulsifier has excellent emulsifying ability to asphalt. The mixing time was over 120 s, which indicated that the emulsifier belongs to slow-set asphalt emulsifier. It can be designed to perform in a wide variety of applications including slurry seal and solventless cold mix applications, for example recycling and base stabilization in asphalt pavement construction.

Conclusion

A novel cationic asphalt emulsifier was synthesized by nonylphenol polyoxyethylene ether, epichlorohydrin and triethylamine. The optimum reaction condition was obtained. The synthesis process was monitored by online FTIR technique and the intermediate was detected. Based upon the experimental data, a plausible reaction mechanism was proposed for the reaction. The emulsifier belongs to slow-set asphalt emulsifier.

Keywords: Coal Tar Pitch; Carbon Fiber; Pre-oxidation Treatment

Abstract. In the preparing process of carbon fiber, the fiber mechanical performance is affected by the pre-oxidation condition. In this paper the pre-oxidation technology condition of the original silk is researched, and the functional group in the molecule and the process of thermal gravimetric of the original silk and pre-oxidized silk are investigated by the method of infrared spectroscopy analysis and thermal gravimetric analysis. The IR analysis shows that associated hydroxyl is disappeared, Ar-H is decreased substantially, and methyl and methylene of the ring structure are changed greatly in the molecule of pre-oxidized silk. The TG analysis shows that the first weight loss temperature is increased, weight loss temperature range is moved to the higher temperature direction, the total weight loss rate is decreased, and weight loss velocity is decreased substantially. The mechanical performance of carbon fiber is affected by the pre-oxidation heating rate. When pre-oxidation heating rate is 1.5℃/min, the breaking strength of carbon fiber is 1195.84Mpa and the Young's modulus is 80Gpa.

Introduction

The coal tar pitch-based carbon fiber is a new kind of chemical material developed in the 1960s. Because of the excellent properties of high strength, high modulus, corrosion resistance, high temperature resistance, fatigue resistance, creep resistance and high thermal conductive, the carbon fiber has been widely applied in aerospace, sports, and medical supplies, automotive and construction industries [1-3]. The manufacture and application research of coal tar pitch-based carbon fiber in China is still in the stage of development, the product property is not stable, and the scale of production is too small to meet the demand of the market [4][5].

The original silk must be pre-oxidized treatment and can't be directly carbonized at high temperature because the original silk is thermoplastic material. asphalt macromolecule can form not-melting and cross-linking structure by being cross-linked in the air, O_2, O_3, CO_2 and other oxidizing atmosphere, keeping the fiber morphology and properties in high temperature carbonization [6].

The IR and TG of the homemade original silk and the pre-oxidized silk are researched by comparison in this paper. The effect of preparation condition on carbon fiber performance is discussed, combined the technology condition of the original silk pre-oxidation and carbonization treatment. The technology parameters are provided for the process of making carbon fiber.

1. Experimental Research Methods

(1) The property of coal tar pitch and the size of original silk such as table 1.

Tab.1. The properties of coal tar pitch and the size of original silk

soft point/℃	coking value/%	QI*/%	TI**/%	original silk size/ μm
275	76.45	5.96	53.91	14.92

* QI: quinoline insoluble, ** TI: toluene insoluble

(2) The condition of pre-oxidation and carbonization

The original silk is placed in the pre-oxidation furnace. The pre-oxidation of the original silk is been doing at the condition of given atmosphere quantum (air flow), according to fixed heating rate and treatment time.

The pre-oxidized silk is carbonized in the carbonization furnace, with 60 ml/min flow into the nitrogen protection, according to certain carbonization heating rate; the terminal temperature carbonization is 1000℃.

(3) The method of sample characterization

The obtained sample of experiment is characterized with the IR (instrument model: WQF-200, Beijing, China), the TG (instrument model: Diamond TG/DTG, America), the SEM (instrument model: Jnsl-5600VL，EJOL, Japan). The mechanical property of carbon fiber is detected by YG004D strength tester.

2. Results and Discussion

2.1 The IR discussion of the original silk and the pre-oxidized silk [7]

The IR of the original silk and the pre-oxidized silk is shown in figure 1.

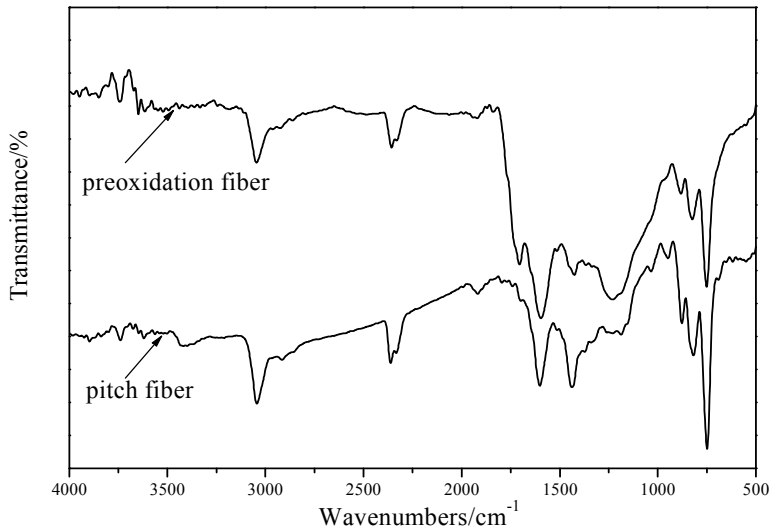

Fig.1. The IR of the original pitch silk and the pre-oxidized silk

The IRs between the original silk and the pre-oxidized silk have obvious difference from figure 1. After the original silk is pre-oxidized, the 3396-3432cm^{-1} absorption peak tends to disappearance. The result shows that the hydrogen bond associated –OH, -NH- are decreased, disappeared finally in the original silk, as the reaction progresses. Strength of the 2920cm^{-1} absorption peak is

weakened, which indicates the -CH_2- and -CH_3 are reduced. Strength of the 1710cm^{-1}, 1220cm^{-1} absorption peak is increased. The phenomenon indicates that carboxyl is increased. Strength of the 945$cm^{-1}$and 882-730cm^{-1} is weakened, which shows that the deformation vibration of the external plane of aryl or the aromatic ring substituents is weakened.

The IR information shows that the chemical structure of pitch is changed, aliphatic hydrocarbon and the aromatic ring substituents are decreased, associated hydrogen bond is disappeared, and the carboxyl is generated after pre-oxidation.

2.2 The TG of the original silk and the pre-oxidized silk

Under the heating rate of 10℃/min, the terminal temperature weightlessness of 1000℃ condition, TG and DTG experimental results are shown in figure 2 and figure 3.

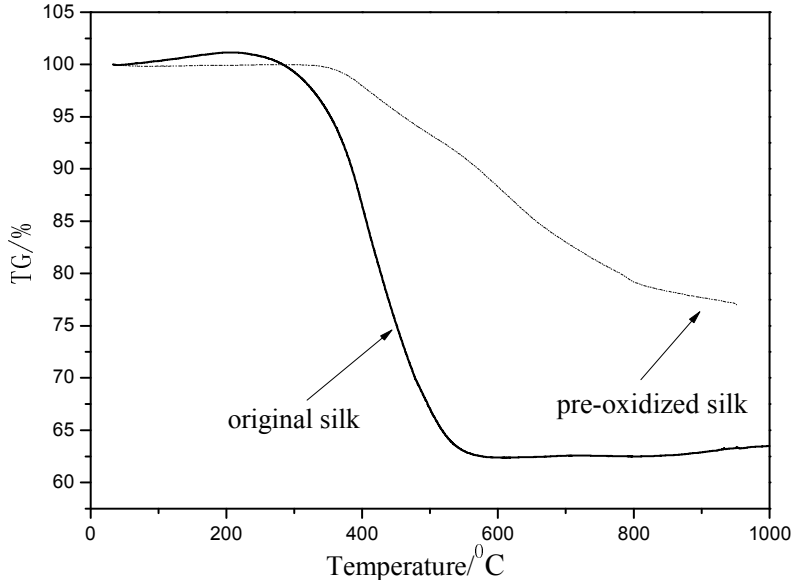

Fig.2. The TG curves of the original silk and the pre-oxidized silk

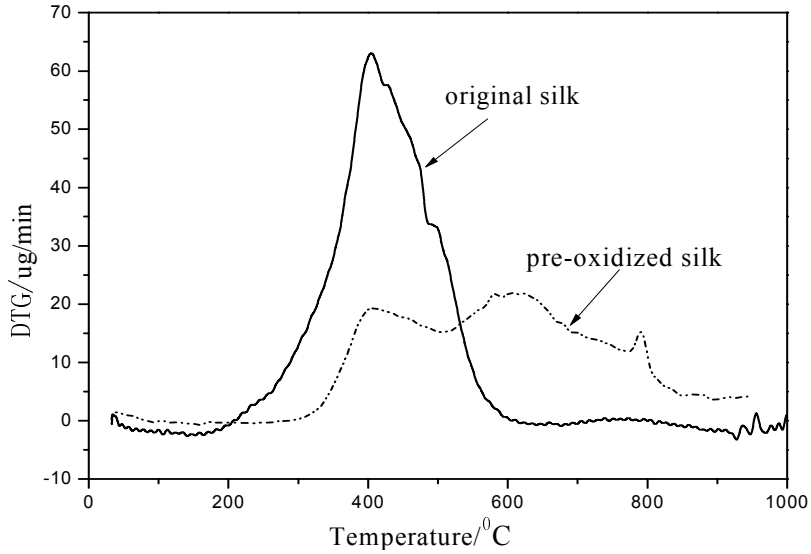

Fig.3. The DTG curves of the original silk and the pre-oxidized silk

By comparing the TG curves of the pre-oxidized silk with the TG curves of the original silk from figure 2, their characteristics of heat weight loss have been greatly changed. The first weight loss temperature of the pre-oxidized silk is increased obviously (the pitch fiber is 291℃, the pre-oxidized silk is 350℃); After the original silk is pre-oxidized, weight loss temperature range is moved to the high temperature direction, the original silk is 291-580℃, and the pre-oxidized silk is 350-950℃; total weight loss rate is decreased (total weight loss rate of the original silk and the pre-oxidized silk respectively is 36.5% and 23.1%); maximum weight loss velocity is decreased substantially after the original silk is pre-oxidized from figure 3.

The experimental results show that, the cross-linking poly-condensation reaction is occurred between pitch molecules after the original silk is pre-oxidized, and then a kind of net structure with thermosetting is generated, the molecular size and the structure of the poly-condensation of which have a major impact on mechanical properties and chemical activity.

2.3 The influence of pre-oxidation treatment condition on the mechanical properties of carbon fiber

The heating rate, terminal temperature and air flow of pre-oxidation have important influence. The condition of pre-oxidation and carbonization such as table 2. The influence on mechanical properties of pre-oxidation heating rate is showed in figure 4.

Tab.2. The pre-oxidation and carbonization conditions of the original silk

Sample	Pre-oxidation heating rate ℃/min	Terminal pre-oxidation temperature/℃	Carbonization heating rate ℃/min	Terminal carbonization temperature /℃
$CF_{0.2}^{0.5}$-08-5	0.5	320	5	1000
$CF_{0.2}^{1.0}$-08-5	1	320	5	1000
$CF_{0.2}^{1.5}$-08-5	1.5	320	5	1000
$CF_{0.2}^{2}$-08-5	2	320	5	1000
$CF_{0.2}^{2.5}$-08-5	2.5	320	5	1000

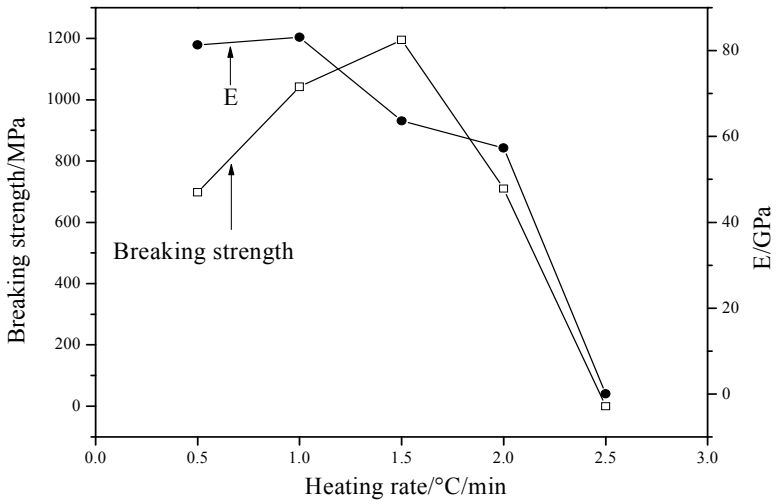

Fig.4.The influence of preo-xidation heating rate on mechanical properties of carbon fiber

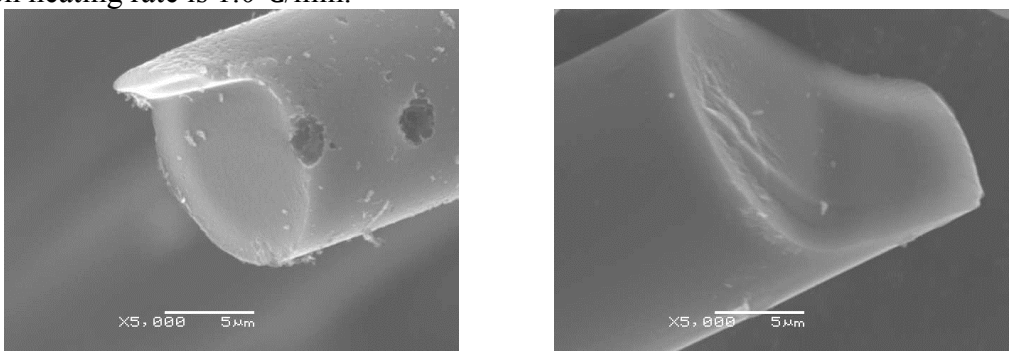
The breaking strength and the Young's modulus of carbon fiber are importantly affected by pre-oxidation heating rate from figure 4. The improvement of breaking strength is affected by the pre-oxidation heating rate, when the pre-oxidation heating rate is too slow, the cross-linking reaction rate too slow , the small weight molecular resin molecules are formed in the original silk molecules and the defects would be shown on the pre-oxidized silk after carbonization ,such as 0.5℃/min, the breaking strength of carbon fiber is 697.70MPa. With the improvement of pre-oxidation heating rate, the breaking strength of carbon fiber is enhanced unceasingly, when the pre-oxidation heating rate is 1.5℃/min, the breaking strength reached the maximum 1195.84Mpa, such as figure 5; Because of the adhesion phenomenon between the original silk, when the pre-oxidation heating rate is continued to rise, the breaking strength of carbon fiber is decreased obviously. The influencing trend of the pre-oxidation heating rate on the Young's modulus is equal

to that of the breaking strength of carbon fiber, the Young's modulus is maximum, when the pre-oxidation heating rate is 1.0℃/min.



(a)0.5℃/min (b)1.5℃/min

Fig.5. The carbon fiber SEM images from the different pre-oxidation heating rate

3. Conclusions

(1) The IR information shows that the chemical structure of the original silk is changed, aliphatic hydrocarbon and the aromatic ring substituents are decreased, associated hydrogen bond is disappeared, and the carboxyl is generated.

(2) After the original silk is pre-oxidized, the first weight loss temperature of the pre-oxidized silk is increased obviously, weight loss temperature range is moved to the high temperature direction, total weight loss rate is decreased, and the velocity of weight loss is decreased substantially.

(3) The breaking strength and the Young's modulus of carbon fiber are importantly affected by pre-oxidation heating rate, the mechanical properties of the carbon fiber are affected by the pre-oxidation heating rate, and the appropriate pre-oxidation heating rate is 1.5℃/min.

Study on the pathway of CS Stimulant with $KMnO_4$ Solution

Xiao'en Zhao

[1] The Engineering University of CAPF Training Department, Xi'an, P.R.China, 710086

wanghe717@163.com

Keywords: CS; KMnO4 Solution; pathway

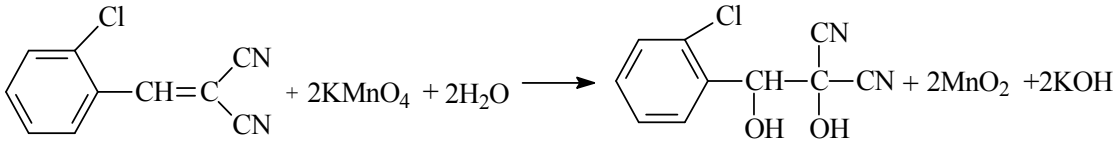
Abstract: On base of the main decomposition approaches for CS, the decontamination pathway on CS stimulant with $KMnO_4$ solution was studied through the UV tests. In this paper, with the purpose of safe decontamination for environment, KMnO4 solution has been chosen to change the CS into non-toxic and non-irritating substances with boric acid as catalyst by oxidation-reduction reaction. The results of test showed that KMnO4 solution at the low concentration can finish the effective and safe decontamination of CS in a short time, which was also in accordance with the requirements of human security.

Introduction

There are three main decomposition approaches for CS, namely pyrolysis, alkaline hydrolysis and redox [1]. limited to stable chemical structure, CS does not break down below 400℃, so pyrolysis can not be used for environmental decontamination; Alkaline hydrolysis belongs to a reversible reaction, whose rate is usual slow that means alkaline hydrolysis is incompatible with the goal of rapid decontamination equally while it only plays a part in a strong alkaline solution. Redox makes use of some strong oxidizability to finish the decontamination of CS and change it into some substances with non-toxic and non-irritating, which is thought of an ideal way among three approaches. As a strong oxidizability, the decontamination pathway on CS for $KMnO_4$ solution was studied through UV tests.

Principle

Although $KMnO_4$ owns strong oxidizing property, its solution with low concentrations can directly act on the human body as a common form of disinfection reagents, which has been reported in clinical application [1, 2]. Therefore, $KMnO_4$ can guarantee the security as environmental decontamination agents. According to the equation of redox reaction, $KMnO_4$ can convert CS into two kinds of byproduct named Pro-chlorophenyl two hydroxy succinic nitrile and manganese dioxide, which were both non-toxic and no stimulating for environment. From the reaction kinetics, the oxidation ability of $KMnO_4$ enhanced a certain degree in acid-catalyzed conditions [3], so using boric acid as a catalyst in the experiments can increase the reaction rate. Boric acid belongs to a kind of tribasic weak acid, it was used to disinfection for clinical wound. Boric acid regulate to the PH value of reaction conditions as a cataelonlyst so that the $KMnO_4$ can better play its oxidation in the weakly acidic environment.



(1)

$$4H_3BO_3+2KOH \longrightarrow K_2B_4O_7+7H_2O \quad (2)$$

TEST

Instruments and medicines

The main instrument used in the experiment were followed: KDM model thermostat water bath (Shandong Province the Juancheng bright instrument Co. Ltd.), JJ model precision increase power electric mixer (Shanghai Pudong Physical Optics Instrument Factory), 1/10000 analytical balance (Swiss Mette Le), vacuum pumps, ball-type water condenser, vacuum distillation head, mouth round bottom flask, three round-bottomed flask, separating funnel, conical bottles, beakers, thermometers and other commonly used laboratory instruments. Chemicals used in the tests were shown in Table 1

Table 1 Characteristics of chemicals used in the test

Chemicals	Formula	Molecular weight g/moL	Product Specifications
CS	$C_{10}H_5N_2ClC_{10}H_5N_2Cl$	188.5	98.9%
Acetone	$C_3H_6OC_3H_6O$	58.0	AR
KMnO4	$KMnO_4$	54.9	AR
Boric acid	H_3BO_3	61.8	AR

Experiment steps

Since CS is almost insoluble in water (solubility of ≤0.01%), acetone should be used as a cosolvent (solubility ≥ 56%) to make sure that CS full contact with the KMnO4 solution. The specific operation should obey as following steps: take appropriate ball CS with medication spoon and press it into powder, then dissolve in acetone by the ratio of 1:1. Operation in the whole process should be pay attention to prevent the CS particles dispersing into the air to cause pollution. Add $KMnO_4$ solution with concentration of 0.02% and excess CS-acetone solution into a 1000ml flask with thermometer and blender, heated and kept the temperature at 30℃. Start the blender immediately after adding boric acid and began to count, and stop stirring after 10min. The reaction rate increased with adding into catalyst, and the mixed solution in the flask was at the state of brown and muddy until the reaction has been accomplished. Reactants must last for 0.5h, when the bottom of the flask appeared with a large number of brown floccose precipitations, which was regarded as manganese dioxide by analysis. Because of its little particle size, manganese dioxide was easy to complex with water, so the floccose precipitation observed is a kind of hydrated manganese dioxide. Hydrated manganese dioxide has a high adsorption capacity, and also includes a small amount of untreated CS.

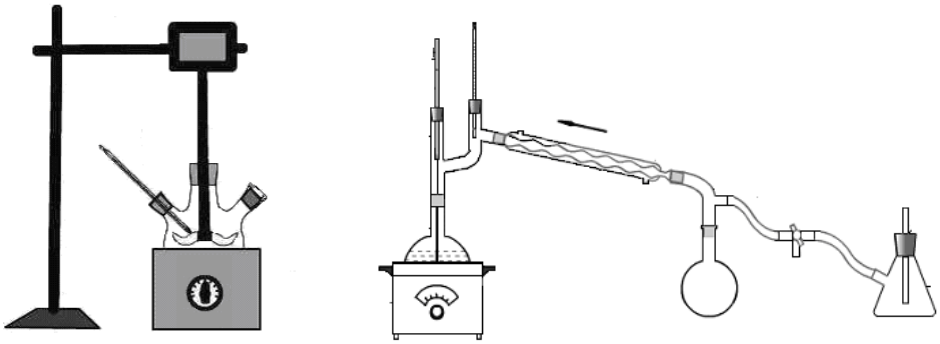


Figure1 Testing apparatus and procedure

Floccose precipitation was usually got rid of by the way of filtration. Due to containing unreacted CS, the residue after separation on the filter paper required to be rinsed three times with acetone at least, and each wash solution need to be collected together retention, in which the

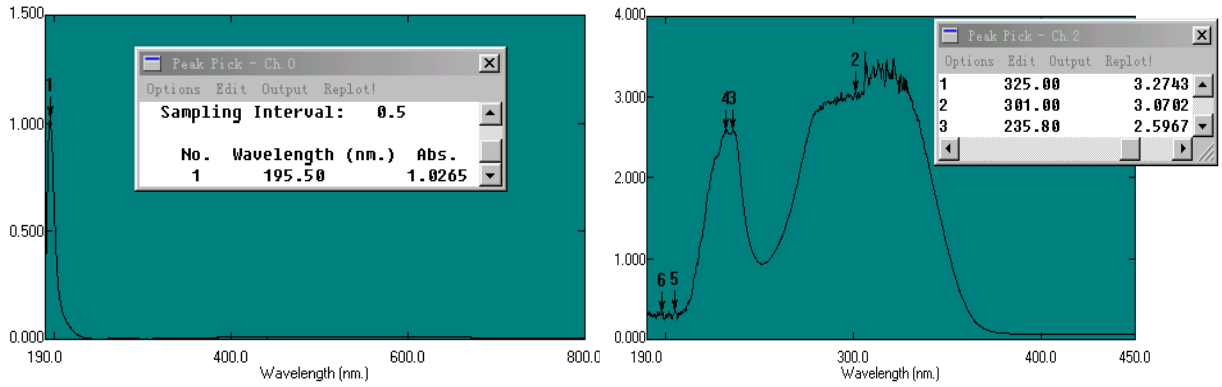
concentration of CS measured. Co solvent acetone in lotion as well as reaction vessel can be removed by vacuum distillation method and reuse in the next tests.

Decontamination effect

The decontamination effect can be weighted up by the reaction conversion rate of CS. in order to estimate the CS conversion rate, it can get the content of unreacted CS by measuring the concentration of CS in the filtrate, which is calculated as follows:

$$\eta = \frac{m_1 - m_2}{m_1} \times 100\% \quad (3)$$

Where, η—*CS* conversion rate, %; m_1—as the quality of the reactants, g; m_2 —remaining CS response quality, g.



(A) $KMnO_4$ solution (B) CS-acetone

Figure2 UV absorption spectra

The concentration of CS in the acetone solution should be measured according to the working curve of absorbance after washing. A UV spectrophotometer was used to measure the absorbance (A) from CS-acetone solution and $KMnO_4$-acetone (boric acid content is so low that it can be ignored), as shown in Figure 2. By comparison, it can be seen that the $KMnO_4$-acetone solution can not form a shield for the absorption peak of the CS, so the working curve can wavelength of 301nm at the absorption peak.

First, Absorbing the CS standard solution 0, 0.50, 1.00, 3.00, 5.00, 7.00, 10.00ml into 50ml color comparison tube and numbered separately; second, adding acetone to 25ml along the wall of the color comparison tube and then mixed. After placing it for 15min, measured its absorbance at a wavelength of 301nm with the cuvette of 30mm optical distance, and take acetone as the reference solution.

According to the Lambert—Beer Law:

$$A=lg1/T=abC \quad (4)$$

Where, *A*—absorbance, *T*—transmittance, *a*—absorptivity, *b*—the thickness of the absorption fluid layer, *C*—concentration of the solution.

When *B* is fixed, then *A* can be given:

$$A=lg1/T=KC \quad (5)$$

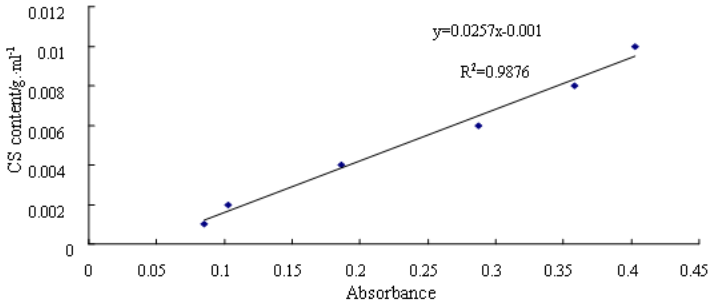


Figure 3 Standard curve

A series of CS-acetone solution with different concentrations were prepared and measured the absorbance (A) at each concentration (C) of 301nm. Corresponding to the CS content as abscissa and absorbance for ordinate, the standard curve was designed as shown in Figure 2.

Conclusions

As a friendly environment decontamination agent, low concentration of $KMnO_4$ can not only carry out rapid decomposition of CS solution but also ensure the safety of users, which has the advantages of shorter onset time and a wide temperature range of options.

Abstract This paper introduces new seawater flocculants. Ferric sulfate solution and polysilicic acid were mixed. After standing and curing, polymeric ferric silicate sulfate was obtained. The optimum preparation process was explored. When Fe/Si=10:20, curing pH in the range of 1.0 to 3.0, flocculants had best flocculating activity. The polymeric ferric silicate sulfate solution and 200 μg/L chitosan solution were mixed to make composite flocculants. Flocculating activity assessments were studied. When pH in the range of 6.0 to 10.0, temperature in the range of 10 ℃to 40 ℃, flocculating activity could be stable. Total phosphorus (TP) and total organic carbon (TOC) removal rates of new flocculants were higher than 80% while algae and bacteria removal rates of new flocculants were all higher than 90%. These flocculants were multi-effect seawater flocculants.

Introduction

Flocculation (in polymer science): Reversible formation of aggregates in which the particles are not in physical contact [1]. Floccunlant is a chemical for producing flocculation of suspended particles, as to improve the plasticity of clay for ceramic purposes. Flocculants are widely used in chemical industry, mining, environmental protection and other fields [2] [3] [4]. In the process of water treatment, flocculants could improve the effect of sedimentation of fine solid [5]. In recent years, along with the development of social economy and population increase, water pollution has become a serious problem. And so on, the treatment of polluted water has become a hotspot. At present, there are multiple ways in water treatment, such as biochemistry, ion exchange, adsorption, chemical oxidation, electro dialysis, etc. But the flocculation process has been confirmed as a widely used water purification process due to its simple operation and low cost [6].

Inorganic flocculant is the most commonly used flocculant. There are two main types: iron and aluminum. According to their molecular weights, they can be divided into two categories, low molecular type and polymer type. Inorganic low molecular flocculant was applied earlier. Now this kind of flocculant is still widely used in the treatment of wastewater. But the effect of them is not ideal in some situations because of its corrosion effect [7]. Inorganic polymer flocculant was invented in 1960's on the basis of the traditional Inorganic low molecular flocculant. This kind of flocculant mostly contains hydroxyl complex ion and bridged poly nuclear complex. These constructions make them huge inorganic polymer compounds. Inorganic polymer flocculants have better flocculating abilities and have become mainstream flocculation reagents [8]. Production and application of inorganic polymer flocculants have a considerable scale in Japan, Russia and Western Europe. Inorganic polymer flocculants accounted for 30%~60% of the total output of flocculants. In recent years, development of polymeric aluminum, iron, silicon, and various kinds of composite inorganic flocculant has become hotspots. Inorganic polymer flocculant varieties have gradually formed series [9].

Seawater desalination is a sunrise industry and has good prospect. Seawater quality defines the efficiency of seawater desalination. However, at present there is not seawater flocculants in the market. Therefore, in this article, we developed new types of flocculants. At the same time, the related functions were studied.

Methods

Flocculating Activity Test

Flocculating activity test was taken by six electric blender. 1 L seawater was put in every beaker. One beaker was control. The other five beakers were added samples. Flocculating process was divided into three phases. In rapid mixing stage, stir speed was 200 rpm and the process lasted 2 min. In slow mixing stage, stir speed was 30 rpm and the process lasted 25 min. In reaction stage, stir was stopped and reaction system stood for 15 min. Supernatant at the top of the solution was taken to measure the residual turbidity.

Flocculating active ratio= (A-B)/A × 100%

A: residual turbidity of control B: residual turbidity of sample

Preparation of Poly Ferric Sulfate (PFSS)

According to different Fe/Si mole ratio, polysilicic acid was slowly added to 20 mL 0.3 mol/L (Fe^{3+} concentration) ferric sulfate solution under magnetic stirring. The constant volume of the solution was 100 mL and final concentration of Fe^{3+} was 0.06 mol/L. Stir was continued and then the solution stood at room temperature for 5 h. At last liquid PFSS was made.

Preparation of Composite Flocculant

Liquid polysilicic acid ferric sulfate was mixed with chitosan solution and stirred at room temperature for 1 h. At last composited flocculant was made.

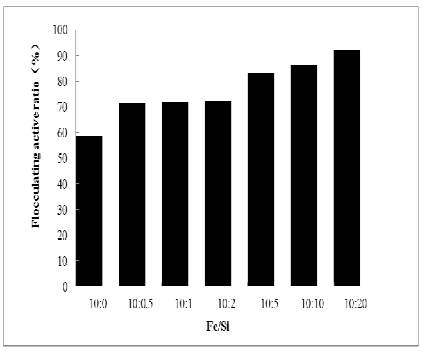
Flocculating Activity Evaluation

Influences of different pH values and environment temperatures were measured. Removal rates of total phosphorus (TP), total nitrogen (TN), total organic carbon (TOC), bacteria and algae were measured to evaluate the effects of this complex flocculant.

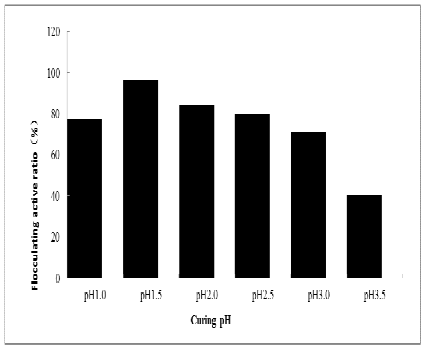
Results and Discussions

Preparation of Poly Ferric Sulfate (PFSS)

Flocculating activity test described in the previous chapter was used. Concentration of Fe^{3+} was 0.03 mol/L. Effects of different Fe/Si ratio on PFSS flocculation were shown in Fig.1.(a). Effects of different curing pH on PFSS flocculation were shown in Fig.1.(b).



(a) Influence of different Fe/Si mole ratio



(b) Influence of different curing pH

Fig.1. Preparation of PFSS

As shown in Fig.1.(a), flocculating activity of PFSS gradually increased with the increase of Fe/Si mole ratio. When Fe/Si = 10:0.5, flocculating active ratio was above 70%. When Fe/Si=10:20, flocculating active ratio reached 95.6% and the residual turbidity was below 2 NTU.

As shown in Fig.1.(b), pH in the range of 1.0 to 3.0, flocculating activity of PFSS kept above 85%. When pH beyond 3.0, a large amount of precipitations occurred, and flocculating activity dropped rapidly.

When the silicic acid polymerized, three-dimensional structure could be loops and nets. The structure led to strong adsorption bridging activity. While polysilicic acid and ferric salt hydrolyze in aqueous solution, a series of positive charge hydrolysis hydroxyl ions were formed and strong abilities of charge neutralization occurred. The combination of polysilicic acid and ferric salt could produce a synergistic effect. Experiments found that turbidity removal rate of this new type of flocculant can reach above 90%.

In addition to these experiments, pH value of polysilicic acid, PFSS curing time, concentration of Fe^{3+} and other parameters that may affect the preparation of PFSS were studied (data not shown). We found that these factors were not main factors affected flocculating effects. In addition, tenfold concentration PFSS could maintain its flocculating activity after a few months. So the initial preparation process had overcome the low concentration and stability compared with the traditional process.

Preparation of Composite Flocculant

Flocculating activity test described in the previous chapter was used. Fe/Si=10:20，Concentration of Fe^{3+} was 0.03 mol/L. Flocculating activities of different concentration of chitosan composited with PFSS were shown in Fig.2..

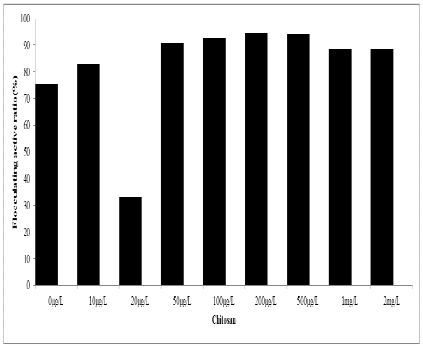


Fig.2. Preparation of composite flocculant

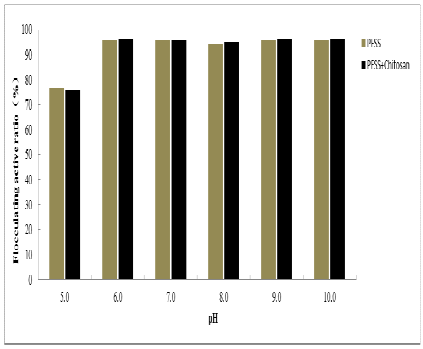
Chitosan had obvious effects on flocculating activity. With the addition of chitosan, velocity of precipitation accelerated, the turbidity removal rate of composite flocculant increased significantly. When the concentration of chitosan reached 200 μg/L, the flocculating active ratio could reach 97%.

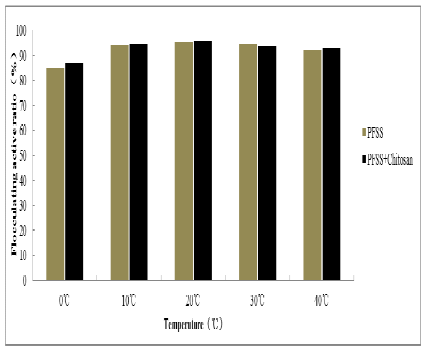
There were a large number of free amino groups on the molecular chain of chitosan. When chitosan was protonated in acid solution, a large number of positive charges appeared on the chitosan chain. This kind of chitosan became a typical cationic flocculant. PFSS composited with chitosan could play advantages of both. Dosage of PFSS and chitosan could be reduced under the premise of maintaining efficacy.

Flocculating Activity Evaluation

Influences of different pH values were measured and shown in Fig.3.(a). Influences of different environment temperatures were measured and shown in Fig.3.(b).



(a) Influence of pH



(b) Influence of temperature

Fig.3. Assessment of flocculating conditions

Different pH values had little impact on flocculating activity. When pH=5.0, the flocculating active ratios of both flocculants were all between 70%-80%. When pH varied from 6.0 to 10.0, the flocculating active ratio of both flocculants were all above 94%. This test suggested PFSS and composited flocculant both had tolerance toward variation of pH values.

Different temperatures had little impact on flocculating activity. When temperatures varied from 0 ℃ to 40 ℃, the flocculating active ratios of both flocculants were all above 80%. This test suggested PFSS and composited flocculant both had tolerance toward variation of temperatures.

Removal rates of total phosphorus (TP), total nitrogen (TN), total organic carbon (TOC), bacteria and algae were measured to evaluate the effects of flocculants. The result was shown in Fig.4..

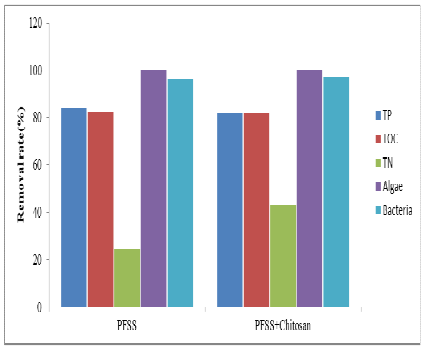


Fig.4. Assessment of flocculating activities

As shown in Fig.4., removal rates of TN were all below 60% while the removal rates of TP, TOC, bacteria and algae were all above 75%. Especially the removal rates of bacteria and algae could reach 90%. The results suggested both PFSS and composited flocculant were multi-effect flocculants.

Conclusion

This article summarizes a method for preparing new seawater flocculants. The optimum conditions of preparing PFSS: Fe/Si=10:20, curing pH 1.0-3.0. The composited flocculant was made by mixing PFSS with 200μg/L chitosan. Both flocculants had stable activities while pH varied from 6 to 10 and temperatures varied from 10℃ to 40℃. Moreover, both flocculants could remove TP, TOC, algae and bacteria from seawater.

Keywords: Corrosion resistance; reflowing technology; tinplate

Abstract Reflowing technology was used to further improve the corrosion resistance of tinplate. Through one-factor experiment, the effects of heating power, heating time, quenching water temperature on the corrosion resistance of tinplate were investigated. The results showed that heating power and time of reflowing had effects on the corrosion resistance of tinplate; The corrosion area of tin layer surface was gradually reduced with the decrease of quenching water temperature, and its corrosion resistance was enhanced. The optimum process was determined as follows: heating power is 410W, heating time is 9s, and the range of quenching water temperature is from 30℃ to 50 ℃.

Introduction

In modern industrial production, tinplate was usually coated with commercially pure tin on both sides of the cold-rolled carbon steel sheet. Tin-plated layer showed good weldability, electrical conductivity, low melting point, strength and punching performance, therefore，tinplate was widely used in the package of electronics and chemical products, also in food canning industry [1-6]. Tin had a tendency to grow whisker under humid conditions, in order to prevent the growth of whisker, reflowing process was often used. Reflowing technology could has a good fluidity of tin solder, and it also could significantly improve bonding strength [7, 8].Suitable reflowing time and temperature could make the grain size of alloy layer on tinplate increase, and also the corrosion resistance would be enhanced[9-11]. In this paper, using reflowing technology, through one-factor experiment, the effects of heating power, heating time, quenching water temperature on the corrosion resistance of tinplate were studied, then the optimum process was finalized.

Experimental

Test specimens was secondary cold-rolled sheet, the anode was titanium. The test piece was heated to a temperature above the melting point of tin by reflow device, the tin layer was melted , then immediately immersed in water to cool it, making it a lustrous tinplate, this was reflowing technology.

Referring to GB / T 6461-2002 " *Assessment and rating on the specimen of metals and other inorganic coatings based on metals after the corrosion test* ", model DCTC1200P salt spray chamber was used to make a salt spray experiment with the specimens.

In the test, the scanning speed of the potential is 0.005V / s; when testing AC impedance, the working potential of sample was kept at the self-corrosion potential , the sine wave signal amplitude was 5mV; the range of scanning frequency was 10mHz ~ 100KHz, scanning speed was 0.01V / s.

For electroplating, coating appearance was an important index to evaluate the quality of coatings. By visual observation method, we could observe the coating , whether there was uniform, peeling, leak-plated, bright, burning, dendritic crystal and other phenomenon, and make a preliminary judgment on the merits of coating.

Results and discussion

Effects of reflowing power on corrosion resistance

Since the melting point of tin was 232 ℃, so the temperature selected in this experiment were higher than 232 ℃. Through exploratory test, the reflowing time was set at 10s. Under other conditions being equal, the tinplate was reflowed at different power, the corrosion morphology of tinplate was analyzed by neutral salt spray corrosion test, the results were shown in Figure 1.

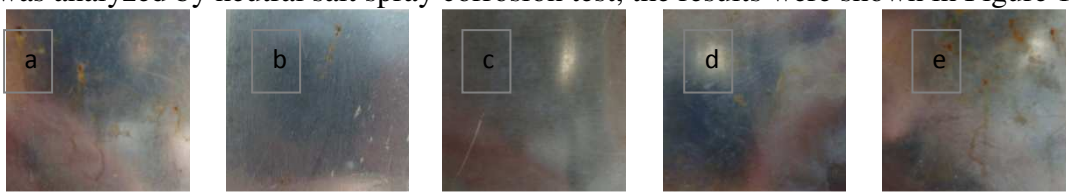

Fig.1.
The corrosion morphology of tin layer at different reflow power
(a) 350W；(b)380W；(c)410W；(d)450W；(e)480W

As we could see from Figure 1: When reflowing the tinplate, heating temperature exceeded the melting point of 232 ℃, the surface of the tinlayer was instantaneously melted, the molten liquid tin flowed into flat rapidly, then it could get a smooth and lustrous surface. When the power was 410W, the flow ability of liquid tin was improved, tinplate reflowed more fully, when reaching full reflowing state, the leveling effect of molten tin layer was more evident, a smooth and shiny tin surface formed (Fig. 1 (c)). However, when the heating power was greater than 410W, the molten tin layer would react with oxygen rapidly, so that the surface morphology of tinplate was destroyed.

Effects of reflowing Power on electrochemical properties

Under different reflowing power, Tafel polarization curves of pure tinlayer corrosion resistance on tinplate were shown in Fig.2, also the corrosion current, corrosion potential and polarization resistance of tinplate were shown in Table 1. It is showed that: with the increase of the reflowing power, the tinplate corrosion potential had a obvious tendency to move forward[12, 13], at the same time, the surface state of tinplate and the structure of tin layer were destroyed ,so ,in the terms of process parameters settings, we must do as much as possible to prevent the generation of

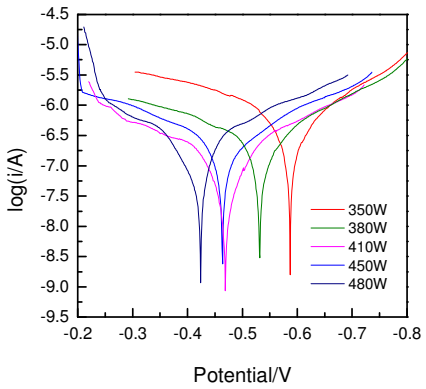

Fig.2Tafel curves at different reflowing power

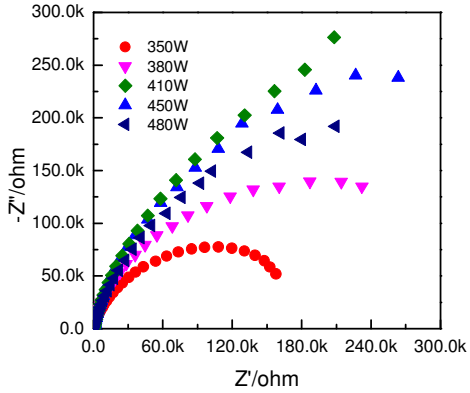

Fig.3EIS spectra at different temperatures

high-temperature oxidation layer.

Under different reflowing power, EIS spectra of pure tin layer corrosion resistance on tinplate were shown in Fig.3. Fig.3 showed that: with the increase of the reflowing power, the impedance radius of tinplate became large, that was to say, the polarization resistance and impedance value became larger, the corrosion resistance was also improved; when reflowing power was above 410W, impedance radius became smaller, and corrosion resistance decreased.

Table 1 The relationship between different parameter of molten tinplate

Reflowing power /W	Corrosion potential /V	Corrosion current /A	Polarization resistance /Ω/cm^2
350	-0.587	4.989×10^{-7}	83913.4
380	-0.532	2.965×10^{-7}	215489.0

410	-0.469	1.066×10^{-7}	471060.2
450	-0.464	3.014×10^{-7}	146627.8
480	-0.424	2.204×10^{-7}	149458.4

Effects of reflowing time on corrosion resistance

When the reflowing power was 410W, at different time, then corrosion morphology of tinplate was analyzed by using neutral salt spray corrosion test , it was shown in Fig.4.

Fig.4 Corrosion morphology of tinplate tin layer under different reflowing time

(a)5s；(b)7s；(c)9s；(d)11s；(e)13s

From Fig. 4 ,it could be seen: when the reflowing heating time was 9s, the flow ability of liquid tin improved, tinplate reflowed more fully ,when achieving the state of full reflowing, the leveling effect of molten tin layer was more obvious, forming a smooth and lustrous tin surface

Effects of reflowing quenching water temperature on corrosion resistance

In order to study the effects of different quenching water temperature on corrosion resistance of tinplate in reflowing technology, under the conditions that reflowing power of 410W, reaction time of 9s, after reflowing treatment, the tinplate was quenched into water of 20 ~ 80 ℃,then made

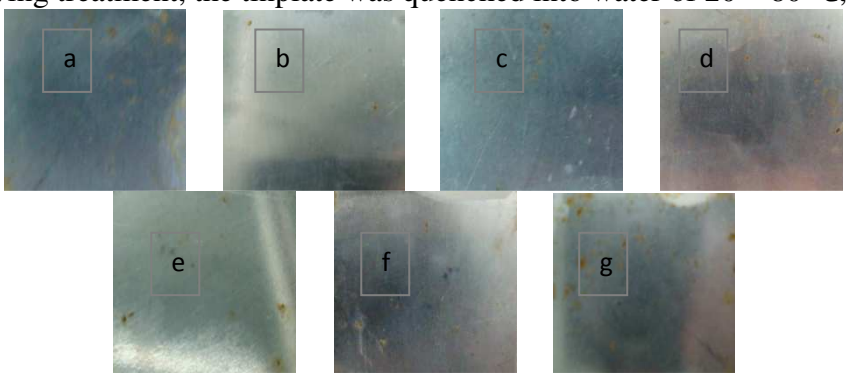

Fig.5 Corrosion morphology of tinplate at different quenching water temperature

(a)20℃；(b)30℃；(c)40℃；(d)50℃；(e)60℃；(f)70℃；(g)80℃

neutral salt spray corrosion test on it, and observed corrosion morphology of the surface.

It could be seen from Fig.5, when the quenching water temperature was 30 ~ 50 ℃ there were small corrosion area, low porosity and good corrosion resistance. within a certain range ,the nucleation rate of metal crystallization increased with the rising of supercooling degree, so the decrease of quenching water temperature could increase the nucleation rate of the tin layer crystallization, and the crystallization was more compact, which was conducive to reducing the probability of exposure of the iron matrix, improving the corrosion resistance of tinned steel sheet.

Conclusion

Reflowing heating power and time had influence on the corrosion resistance of tinplate . With the increased reflowing power or extended time, the corrosion area of tinplate surface decreased, the corrosion current and corrosion potential significantly reduced and moved forward, and thus improved its corrosion resistance.In the reflowing technology, when the quenching water temperature was different, due to the different supercooling degree of tin layer crystallization, the impact on the corrosion resistance of tinplate was different. With the decrease of quenching water temperature, the corrosion area of tinplate surface was gradually reduced, it indicated that the number of pinholes had a tendency to decrease, and its corrosion resistance improved.

Keywords: X80 Pipeline Steel; Bainite/Ferrite Two Phases; Plasticity; Work Hardening; Strain Distribution

Abstract. The effect of volume fraction of ferrite on the mechanical properties including strength, plasticity and wok hardening was systematically investigated in X80 pipeline steel in order to improve the plasticity. The microstructures with different volume fraction of ferrite and bainite were obtained by heat-treatment processing and the mechanical properties were tested. The work hardening behavior was analyzed by C-J method. The results show that the small amount of ferrite could effectively improve the plasticity. The work hardening ability and the ratio of yield/tensile strength with two phases of ferrite/bainite would be obviously better than that with single phase of bainite. The improvement of plasticity could be attributed to the ferrite in which more plastic deformation was afforded.

Introduction

In order to improve the application safety of pipeline steels, especially applicable in the case of bad geological conditions such as landslide and earthquake, etc, it is very increasingly interested that to enhance the plasticity of high-strength pipeline steels [1] [2]. The plasticity enhancement of pipeline steels is currently developed by introducing of soft ferrite phase based on the physical principle of dual-phase steels applicable to auto manufacturing [3] [4] [5] [6]. However, it should be noted that there are two intrinsic difference in two steels of pipeline and dual phase steels, firstly the ferrite is small volume fraction of about 10-20% in pipeline steels [6] whereas ferrite is 70-80% in dual phase steels [7]; sencondly ferrite and bainite are phase components in pipeline steels whereas ferrite and martensite are phase components in dual phase steels [8]. It is required to understand the effect of ferrite volume fraction on the mechanical properties of high strength pipeline steels. In the present work, the volume fraction of ferrite was introduced in commercial X80 pipeline steel. The yield/tensile strength and plasticity were systematically investigated experimentally. The work hardening behavior was analyzed by C-J method was investigated.

Experiments

Commercial X80 line pipe steel was used as experimental material. The composition of the steel was listed as table 1.

Table 1 The composition of the experimental steel

C	Si	Mn	Cr	Nb	Ni	Cu	Mo
0.038	0.237	1.94	0.025	0.069	0.245	0.179	0.31
P	S	V	Ti	Al	W		
0.01	0.0009	0.006	0.011	0.018	0.069		

The specimens were reheated to different temperature and hold for different time in order to obtain different ferrite volume fraction. The samples were then quenched by oil at about cooling rate of 30℃/s in order to promote phase transformation of austenite to bainite. The heat-treatment processing was shown in figure 1. The Ac1 and Ac3 temperatures were measured by Gleeble 3500. The samples were made as standard specimens for mechanical properties measurement. The microstructures of the samples were observed in Olympus X51 optical metallography. The mechanical properties were measured in CMT4150 materials test.

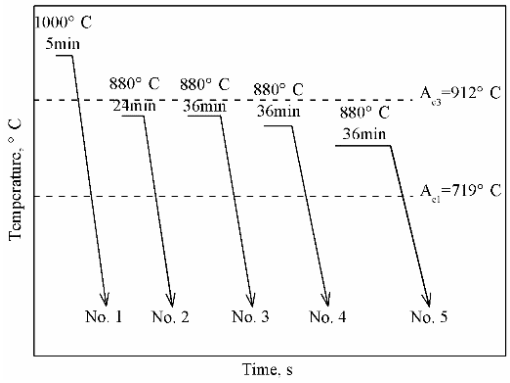

Fig. 1. The heat-treatment processing

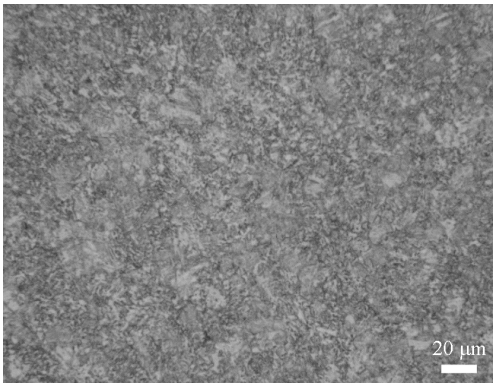
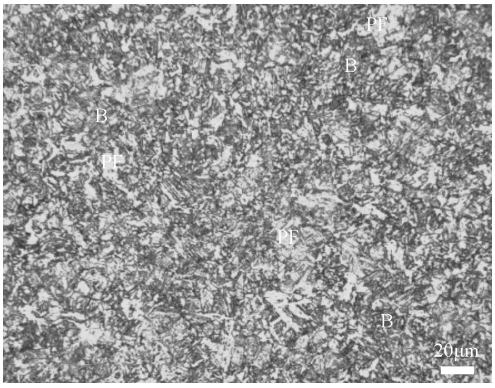
Results and Discussion

The microstructure of the sample No.1 which was reheated to 1000℃ hold 5 minutes and then quenched was shown in figure 2(a). It could be seen that almost fully bainite microstructure was obtained. The microstructures of samples with different heat treatment processing would be two phase components of ferrite and bainite as typically shown in figure 2(b). The volume fraction of ferrite with different heat treatments was listed in table 2.



(a) Microstructure of the sample No. 1



(b) Typical microstructure of bainite/ferrite two phase

Fig. 2. Typical microstructures of the samples after heat-treatments

Table 2 Volume fraction of the samples after different heat-treatments

Steel	No. 1	No. 2	No. 3	No. 4	No. 5
Volume of ferrite, %	<2%	5.11%	15.68	20.04	30.58

The stress-strain behavior of all samples exhibited continuous yield. The mechanical properties as the function of volume fraction of ferrite was shown in table 3. It could be seen that the yield/tensile strength would be decreased as the volume fraction of ferrite increased but the elongation would be enhanced. It should be noted that the yield and tensile strength could be still about 600MPa and 820MPa respectively when the ferrite volume fraction reached to 15.68%. The yield and tensile strength were decreased about 5.9% and 6.1% respectively. However, the uniform elongation was increased up to 32.4%. It is applicable to improve anti-deformation ability by introducing small volume fraction of ferrite.

Table 3 Volume fraction of the samples after different heat-treatments

Steel	True stress/strain						
	R_m, MPa	$R_{0.2}$, MPa	$R_{0.2}/R_m$	HV	ε_u	ε_t	Z, %
No. 1	875.62	636.81	0.727	295.30	0.0377	0.1441	81.63
No. 2	856.31	630.91	0.737	277.55	0.0475	0.1532	85.03
No. 3	821.86	598.93	0.729	261.25	0.0499	0.1587	84.17

No. 5	776.62	482.22	0.621	255.93	0.0688	0.1739	83.65

According to A. Kummar and A. Bag's work [8] [9], the work hardening could be divided into three stage during deformation processing in two phase steels. The first stage is homogenous plastic deformation occurred only in soft phase (m_I), the second stage is inhomogeneous plastic deformation occurred in soft phase because the restraint of the hard phase without plastic deformation (m_{II}) and the third stage is soft and hard phase coordinated deformation (m_{III}). C-J analysis method [10] was applied in the present work for investigation of the effect of ferrite volume fraction of work hardening behavior. There was no m_I stage could be found in all of the samples which could be due to small amount of ferrite volume fraction and very small grain size. When ferrite grain size is small enough, the deformation could not be homogeneous because interface impede of phase boundaries. Only one stage could be observed in full bainite microstructure as shown in table 4. The stage of m_{II} and m_{III} could be observed as shown in table 4, which implied that the plastic deformation firstly occurred in ferrite. As shown in table 4, the m_{III} stage always occurred at the strain larger than 0.002%, which implied that the plastic deformation occurred after macro yield. As the volume fraction of ferrite increased, the start strain where the m_{III} stage starting would be increased. The plastic deformation was firstly occurred in ferrite to give plasticity and then when the stress accumulation at the phase boundaries was overcome the yield stress for bainite, the plastic deformation was occurred in bainite resulting in different work hardening behavior. It could be concluded that the improvement of plasticity could be attribute to the prior deformation in ferrite.

Table 4 The stress exponent of m_{II} and m_{III} stage, and the start stress and strain where the m_{III} stage starting

Summery

The improvement of plasticity could be obtained by introducing soft ferrite in X80 pipeline steel. Although the yield and tensile strength would be decreased by introducing the ferrite, the plastic elongation would be obviously increased. The two stage work hardening behavior could be observed in ferrite/banite two phase microstructure instead of only one stage work hardening in full bainite microstructure. This resulted improvement of yield/tensile strength ratio. The plasticity enhancement of ferrite/bainite pipeline steel could be attributed to the prior deformation in ferrite.

Keywords: Computer simulation, Elastic constants, Band structure, Bulk modulus

Abstract. The crystal structures, lattice parameters, volumes, elastic constants, bulk moduli and shear moduli of the binary NiAl and Ni_3Al alloys have been predicted by taking the first-principles plane-wave method in combination with ultra-soft pseudo-potentials. Also the pressure dependence of C_{ij}, B and G are described and quantitatively discussed. The calculated results agree with the experimental data. The elastic constants obtained from our calculations meet their mechanical stability criteria. The DOS results show that the strong Ni-Al interaction plays an important role in the chemical bond of the Ni-Al alloys. Our predictions should be testified by the experimental investigations.

Introduction

The high melting point intermetallics NiAl and Ni_3Al have outstanding physical and mechanical properties [1]. Advanced Ni-Al alloys for structural applications in energy conversion systems are currently under development [2]. NiAl and Ni_3Al super alloys have been widely used for turbine blades, structural applications and engines for space projects due to their high strength, unique mechanical property, elevated thermal stability and good corrosion resistance under extreme conditions [3, 4]. Ni-Al binary systems have also been used as nuclear reactors due to the low density, low weight and high melting point [5, 6]. Besides, NiAl is an excellent alumina-scale former with good thermo-mechanical properties and it has been carefully used in a wide range of modern industry [7, 8]. NiAl crystallize in cubic structure (space group: *PM-3M*). The Ni and Al atoms occupy the (0.5, 0.5, 0.5) and (0, 0, 0) Wyckoff positions, respectively [9]. The Ni_3Al alloy has a face-centred cubic lattice (space group: 221). Different atoms occupy the Ni (0.5, 0, 0.5) and Al (0, 0, 0) sites. The lattice parameters of Ni_3Al are a=b=c=0.3568nm [10].

Shang et al. [11] have investigated some fundamental thermal properties (thermal expansion coefficient, bulk modulus, entropy, enthalpy and heat capacity) of Ni and Ni_3Al through the first-principles projector-augmented wave method. Saadi et al. [12] have determined the structure and surface composition of the NiAl (110) and Ni_3Al (111) at conditions relevant for metal dusting. The elastic anisotropy and phonon focusing of NiAl have been predicted using ultra-soft pseudopotentials within the framework of density functional theory [13]. Recently, the structural, elastic and electronic properties of NiAl with rare earth element Ce have been obtained by using first-principles calculations [14]. Generally speaking, the physical properties of NiAl and Ni_3Al have been widely studied by different experiments and theoretical works. Nevertheless, the band structure and density of states are less investigated, especially at high pressures.

The aim of this paper is to predict the electronic structures (band structure, DOS) of NiAl and Ni_3Al through first-principles calculation. The detailed bonding interactions in these alloys are also analysed in this work. This paper is organized as follows. The computational details are given in the following section, i.e. Section 2. Section 3 describes the calculated results and the corresponding discussions. At first, we describe the crystal structure and elastic constants of NiAl and Ni_3Al. Then,

we show the DOS and band structure to analyse the chemical bonding of the two alloys. Finally, some brief conclusions are illustrated in Section 4.

Crystal structure and calculation scheme

In our computations we used the first-principles density functional theory. Namely, the structural and elastic properties were predicted within the plane-wave pseudo-potential method [15]. A plane-wave cutoff energy of 330eV was used in our scheme. According to the Monkhorst-Pack girds [16], the k-point meshes of 10×10×10 and 8×8×8 were used for NiAl and Ni_3Al, respectively. The Perdew-Burke-Ernzerhof (PBE) functional was applied to the exchange-correlation relationship [17]. The Al-$3s^2 3p^1$ and Ni-$3d^8 4s^2$ states are treated as valence electrons. The convergence of total energy was set to be 10^{-6}eV/atom.

Results and discussions

Appling the above-mentioned plane-wave pseudo-potential method, the computed lattice parameter a, cell volume V, elastic constants C_{ij}, bulk modulus B and shear modulus G of NiAl and Ni_3Al at different pressures are listed in Table 1.

Table 1. Lattice constant, cell volume, elastic constants, bulk modulus and shear modulus of NiAl and Ni_3Al under pressures.

	P /GPa	a /nm	V /Å^3	C_{11} /GPa	C_{12} /GPa	C_{44} /GPa	B /GPa	G /GPa

	15	0.2823	22.51	224.19	210.20	140.33	214.86	51.63
	25	0.2784	21.58	266.83	250.33	169.26	255.83	62.04
	35	0.2751	20.81	307.66	288.57	195.59	294.93	71.71
	0 [1]	0.2900	24.38	198.00	137.00	116.00	157.33	--------
Ni_3Al	5	0.3549	44.71	296.71	151.11	64.23	199.64	67.53
	15	0.3497	42.76	356.16	189.31	74.85	244.93	78.17
	25	0.3456	41.29	391.49	218.85	75.74	276.41	79.81
	35	0.3418	39.95	449.11	255.86	85.37	320.28	89.71
	0	0.3572[18]	45.57[3]	225.30[3]	157.60[3]	121.10[3]	180.20[3]	72.90[3]

The lattice constants and elastic moduli of NiAl and Ni_3Al are listed in Table 1. As it can be seen in Table 1, the calculated lattice constants agree well with the experimental data [1, 18]. The maximum relative errors for lattice parameter and bulk modulus are 1.0% and 9.9%, respectively. This is within the general accuracy of GGA for lattice constant (usually 1～2%) and bulk modulus (5～10%). This has proven the reliability of our calculation. As shown in Table 1, the elastic constants C_{ij}, B and G increase with applied pressure, but the slopes are different. The elastic constant C_{11}, which corresponds to the longitudinal wave v_{p1} propagated along [001], increases dramatically with the increasing temperature. C_{44} increases slowly with the elevated temperature, which indicates that the velocity of shear wave v_{s1} propagated along [110] or [001] will be faster as the pressure increases. For the cubic NiAl and Ni_3Al alloys, the mechanical stability rules are $C_{44}>0$, $C_{11}-C_{12}>0$ and $C_{11}+2C_{12}>0$ [19]. All the elastic constants listed in Table 1 satisfy these rules, which indicate that the two alloys are mechanically stable in the pressure range of 5—35GPa.

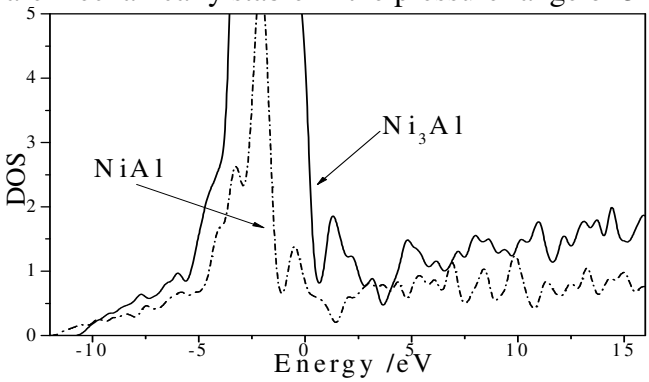

Fig. 1. Total density of state (TDOS) for NiAl (dotted line) and Ni_3Al (dashed line) at 15GPa.

The calculated TDOS of NiAl and Ni_3Al are plotted in Fig. 1. The origin of the energy is located at the Fermi energy level E_F. There is no gap at 0eV, which indicates that NiAl and Ni_3Al belong to metallic materials. The DOS of NiAl is broader than that of Ni_3Al, which reflects that the electrons in Ni_3Al are more localized than the electrons in NiAl. There is no gap appears in the whole energy region, which shows the strong Ni-Al interactions in these alloys. The DOS at E_F are 0.82 and 4.19 for NiAl and Ni_3Al, respectively. The corresponding electronic specific heat coefficients γ are 1.93 and 9.88 J/mol·cell·K^2 ($\gamma=nk_B^2\pi^2/3$, where k_B is the Boltzmann's constant [20]).

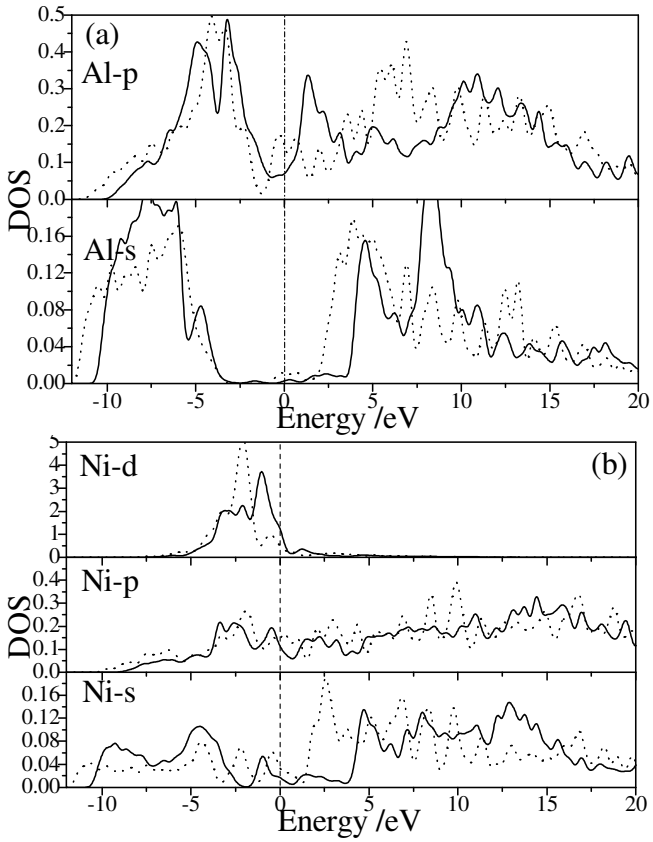

Fig. 2. Spin-averaged density of state projected on to the (a) Al and (b) Ni atoms.

In Fig. 2, the valence band can be clearly divided into two regions, namely the lowest region (below -5eV) and the lower region (-5---0eV). The lowest region is mainly composed of the Al-s and Ni-s bands. The lower region is mainly contributed by the Ni-d, Ni-p and Al-p states. The Ni-d band is much stronger than the other bands. The DOS at E_F is mainly contributed by the Ni-3d state, which is not entirely filled. The conduction band is contributed by the Ni-p, Ni-s and Al-p bands. NiAl is more stable than Ni_3Al, the stability of the Ni-Al compound decreases with the Ni concentration. More importantly, the DOS of NiAl and Ni_3Al are similar with each other.

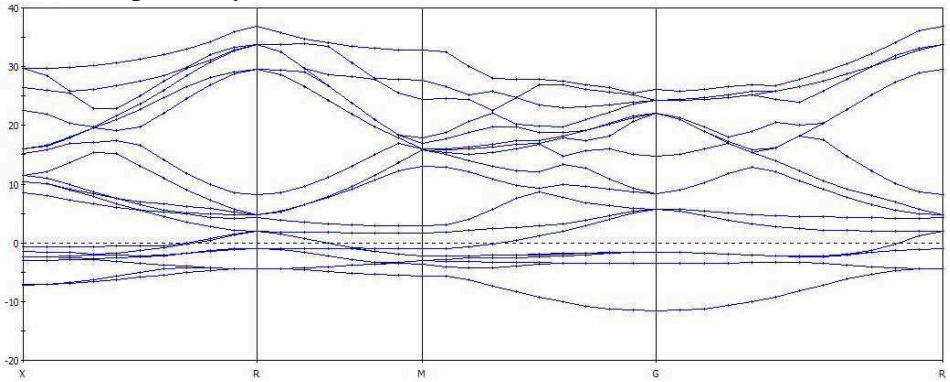

Fig. 3. Calculated electronic band structure of NiAl at 15GPa.

Figs. 3 and 4 show the calculated band structures of NiAl and Ni_3Al along the select high symmetry points X, R, M and G (Γ point), respectively. The band structure curves drawn in Fig. 4are very similar to those of Hussain et al. [10] and Rhee et al. [21]. The energy gap, defined as the difference between the energies of the conduction band and valence band, does not exist in these two compounds, because we could not observe any gap in Figs. 2 and 3. This is also in agreement with the fact that NiAl and Ni_3Al have metallic characters. The densities of states are concentrated in the energy range of -5—0eV (the reciprocal lattice of W to K), which indicates that most bands are not in the centre Γ point.

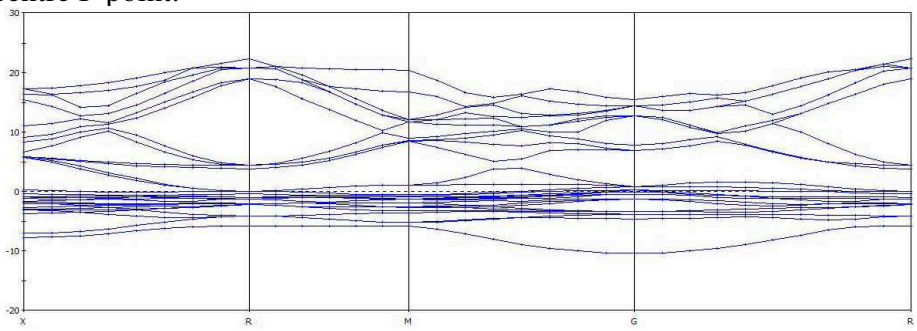

Fig. 4. Band structure of Ni_3Al along some high symmetry points (at 15GPa).

Conclusions

In this work, the first-principles calculations have been performed to study the binary NiAl and Ni_3Al alloys on the structural, elastic and electronic properties in the pressure range of 5—35GPa. The calculated results agree well with the experimental data. The two alloys are mechanically stable under different pressures. All the elastic constants and elastic moduli increase with applied pressure, but the slopes are different. The DOS shows that the band near the Fermi energy are highly localized, which is mainly contributed by the Ni-3d band. The conduction band is completely delocalized. Generally speaking, our predictions need to be verified by the other investigations

Keywords: Computer simulation, Lattice constant, Reflectivity, Dielectric function

Abstract. Using quantum mechanics plane-wave approach based on the density functional theory, the lattice constants of Ni_xAl at different Ni concentrations (x=1, 3) are predicted. Optical properties such as dielectric function, energy loss function and reflectivity are also investigated. Results show that with the increase of Ni constituent, the location of the peak in loss function moves to the lower energy region, but the peak height increases. At 0eV, the reflectivity increases rapidly with the Ni concentration. The reflectivity of NiAl and Ni_3Al are pronounced in the UV region (not in the visible light region). The dielectric properties, namely the real and imaginary parts of the dielectric function, changed significantly with Ni constituent.

Introduction

Ni-Al constructional alloys play an important role for a wide range of technical applications due to their good corrosion resistance and enhanced strength under extreme conditions [1-3]. To protect engine components made from different alloys from thermo-mechanical failure, the high-temperature Ni-Al binary alloys have been developed to improve their high-temperature hardness at elevated temperatures [4]. The NiAl alloys reveal several interesting properties including low density (about 6 g/cm^3), high melting temperature (1911K) and good oxidation resistance up to 1573K, as well as excellent thermal conductivity [5]. Recently, the laser post-ionisation measurement [6] reflects that the excitation energy, the electron configuration and the band structure have significant effects on the formation of an excited Ni/Al atom [7]. As we all know, the NiAl alloy has a body-centred cubic structure (space group: 221), the Al and Ni atoms occupy the (0, 0, 0) and (0.5, 0.5, 0.5) Wyckoff sites, respectively [8]. Ni_3Al crystallizes in the face centred cubic lattice (space group: 221), different atoms occupy the Ni (0.5, 0, 0.5) and Al (0, 0, 0) positions [9].

The equilibrium lattice parameters, lattice constants, cohesive energies, effective formation energies and self-diffusions in NiAl and Ni_3Al have been determined by molecular dynamics [10] and the analytical embedded atom method [11]. Generated by modifying the aluminium content in Ni_3Al, Takizawa et al. [12] have obtained the $L1_0$ structure of NiAl and have investigated the large distortion in its *c*-axis. Tang et al. [13] have studied the growth behaviour of Ni_3Al layer (shape evolution, growth kinetics) in the β/γ couple of Ni-Al alloys. More importantly, the growth of layers or the formation of ordered 2D over-layers of the Ni-Al binary alloys have been carried out for the Ni (111) [14], NiAl (110) [2], Ni (100) [3] and Ni_3Al (100) planes [3]. Generally speaking, most works are concentrated on the mechanical, physical and thermal properties of NiAl and Ni_3Al. The optical properties of these compounds are less studied. It is worthy of note that the optical properties of metals are directly related to their fundamental properties such as band structures, defects, lattice vibrations and magnetic excitations. Therefore, it is very important to obtain the optical properties of NiAl and Ni_3Al alloys.

The purpose of this study is to investigate the optical properties of Ni-Al based alloys and to determine the fundamental properties which is related to optical properties. The rest of this paper is organized as follows. Section 2 describes the calculation methodology of this work. Section 3 introduces the calculated results and discussions. Finally, I conclude the paper in Section 4.

Crystal structure and calculation scheme

In our computations we used the first-principles density functional theory. Namely, the structural and elastic properties were predicted within the plane-wave pseudo-potential method [15]. A plane-wave energy cutoff of 330eV was used in our scheme. According to the Monkhorst-Pack girds [16], the k-point meshes of 10×10×10 and 8×8×8 were used for NiAl and Ni_3Al, respectively. The Perdew-Burke-Ernzerhof (PBE) functional was applied to the exchange-correlation relationship [17]. The Al-$3s^2 3p^1$ and Ni-$3d^8 4s^2$ states are treated as valence electrons. The convergence of total energy was set to be 10^{-6}eV/atom.

Results and discussions

Firstly, we have investigated the lattice constants. The computed lattice constants of NiAl and Ni_3Al are 0.2901nm and 0.3580nm, respectively. This is in excellent agreement with the experimental data (0.2880nm for NiAl [18] and 0.3572nm for Ni_3Al [19]). Through the above-mentioned first-principles method, we have calculated and plotted the reflectivity of NiAl and Ni_3Al in Fig. 1.

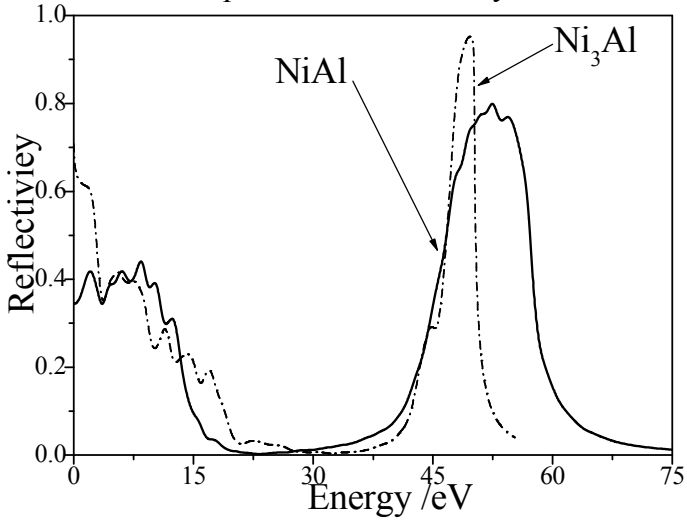

Fig. 1. Optical reflectivity *R* of the NiAl and Ni_3Al alloys.

Then, the optical reflectivities *R* were calculated and drawn in Fig. 1. The optical reflectivity can be determined by the relationship $R=[(n-1)^2+k^2]/[(n+1)^2+k^2]$ [20], where *n* and *k* are the reflective index and extinction coefficient, respectively. The reflectivity spectra shows moderate values near 4.5—12.4eV, the average *R* reaches up to 40%, almost 1/2 visible light is reflected, the materials have metal reflection characters. At 0eV, the first edge values of *R* are 34.6% and 70.7% for NiAl and Ni_3Al, respectively. The main peaks of the curves appear at 45—52eV, which reflects that *R* is more pronounced in the UV region. Besides, the maximum values of *R* are 79.7% and 95.2% for NiAl and Ni_3Al, respectively.

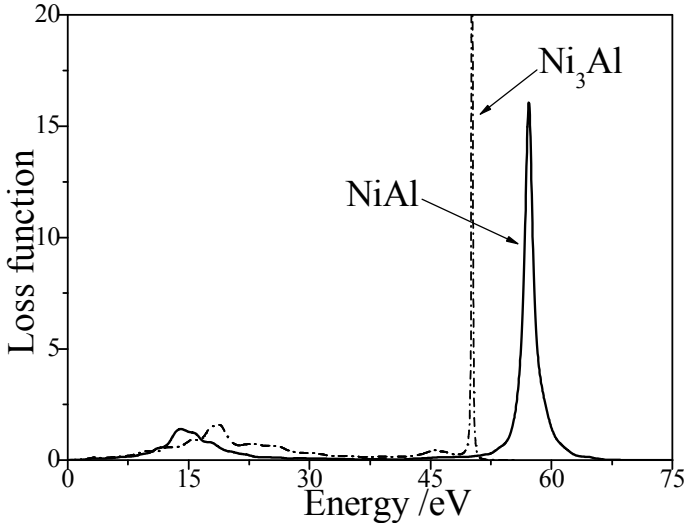

Fig. 2. Energy loss function L of the NiAl and Ni_3Al alloys.

The energy loss function L is an important index which describes the energy loss of a fast electron traversing in a solid [21]. The calculated loss function of NiAl and Ni_3Al are plotted in Fig. 2. The main peak in L spectra represents the plasma resonance, which means a collective oscillation of the valence electrons. The main peak corresponds to the plasma frequency ω_P. The peaks locate at 58 and 47eV for NiAl and Ni_3Al, respectively. At these energies the real part of the dielectric function vanishes. The location of the peak decreases with the Ni concentration, while the peak height increases with the Ni concentration.

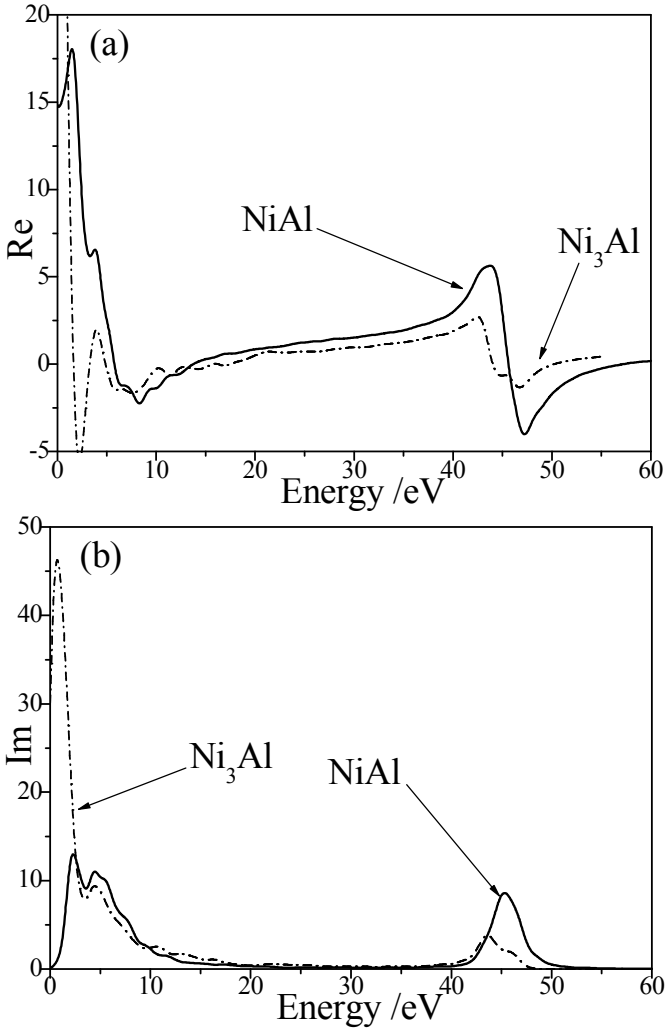

Fig. 3. Calculated (a) real and (b) imaginary parts of dielectric function of NiAl and Ni_3Al.

As the bridge between microcosmic physics process of electrons emission and the macroscopic electronic structures, dielectric function response the band structure and other spectral information of solids [21]. The dielectric function ε can be determined by $\varepsilon=\varepsilon_1+i\varepsilon_2$, where ε_1 and ε_2 are the real part and the imaginary part of the dielectric function, respectively [22]. The real parts of the dielectric functions of NiAl and Ni_3Al are shown in Fig. 3(a). The static dielectric constant $\varepsilon(0)$ and the high-frequency dielectric constant $\varepsilon(\infty)$ can be obtained at 0eV and the energy limit ∞, respectively. Therefore, $\varepsilon(0)$ and $\varepsilon(\infty)$ are 14.88 (129.58) and 0 (0) for NiAl (Ni_3Al), respectively. In Fig. 3(b), the imaginary parts increases from 0eV, which shows that the energy band gap of the two alloys are 0eV (metallic characters).

Conclusions

We studied the optical properties of Ni-Al binary alloys by using the first-principles plane-wave method with the famous PBE exchange-correlation functional. The calculated lattice constants are in good agreement with the experimental data. The static dielectric constant increases rapidly with the Ni concentration. The Ni constituent can also significantly influence the optical dielectric function. The location of the peak in the loss function decreases with the Ni concentration, while the peak increases with the Ni concentration. The reflectivity indicates that *R* is more pronounced in the UV region (not in the visible light region). As a metal, Ni-Al alloy has a suitable band gap of 0eV.

Keywords: TiO_2-based; Composite film; photodegradation

Abstract. A simple process was developed for preparation of highly photoactive Fe and S codoped TiO_2-SiO_2-ZnO composite film. The Brunauer–Emmett–Teller (BET) surface area results showed that the specific surface area of the composite TiO_2 sample was 432.5m^2g^{-1}, while that of the pure TiO_2 was 103.4m^2g^{-1}. The diffuse reflectance measurements exhibited an extension of light absorption into the visible region for the composite TiO_2. The photoluminescence (PL) spectra analysis indicated that the electron-hole recombination rate was effectively inhibited in the composite TiO_2. The photocatalytic activities of the TiO_2 films were evaluated by the photocatalytic decomposition of methyl green in aqueous solution. The composite TiO_2 film exhibited excellent photocatalytic activities compared to pure TiO_2 film.

Introduction

The reuse and recycling of wastewater effluent is rapidly growing due to limited fresh water supply in the world. However, it is difficult to remove them by traditional pollutant treatment methods. Semiconductor heterogeneous photocatalytic oxidation process is a popular technique that has great potential to remove organic dyes in wastewater. Among various semiconductors, titanium dioxide is considered as the most useful photocatalyst owing to its long-term stability, lowtoxicity, chemical and biological inertness, controllable structure and morphology, strong oxidizing power, as well as its low cost [1-3].

In this paper, we report the Fe and S codoped TiO_2-SiO_2-ZnO composite films with an attempt to increase the specific surface area of the TiO_2-based photocatalyst, extend light absorption of TiO_2 into the visible region and reduce the rapid recombination of photogenerated electron and holes. We have investigated the effect of the co-modifying on the photocatalytic degradation of methyl green.

Experimental

All chemicals used in this study were analytically pure. TiO_2 colloid or SiO_2 colloid was prepared through the sol-gel method [4, 5]. TiO_2-ZnO composite colloid was prepared by the following method. 1mL tetrabutyl titanate ($TiO(C_4H_9O)_4$) was added dropwise to 20mL absolute ethanol in a clean vessel, and 20 mL 0.2M nitric acid contained 100mg zinc nitrate were added to the above solution under vigorous stirring. After 24h aging, the composite colloidal TiO_2-ZnO could be obtained. TiO_2-SiO_2 composite colloid was prepared by mixing TiO_2 and SiO_2 colloid in a 2/1 in volume ratio under strong stirring. After 24h aging, the composite colloidal TiO_2-SiO_2 could be obtained. TiO_2-SiO_2-ZnO composite colloid was prepared by mixing colloidal TiO_2-ZnO and SiO_2 in a 2/1 in volume ratio under strong stirring.

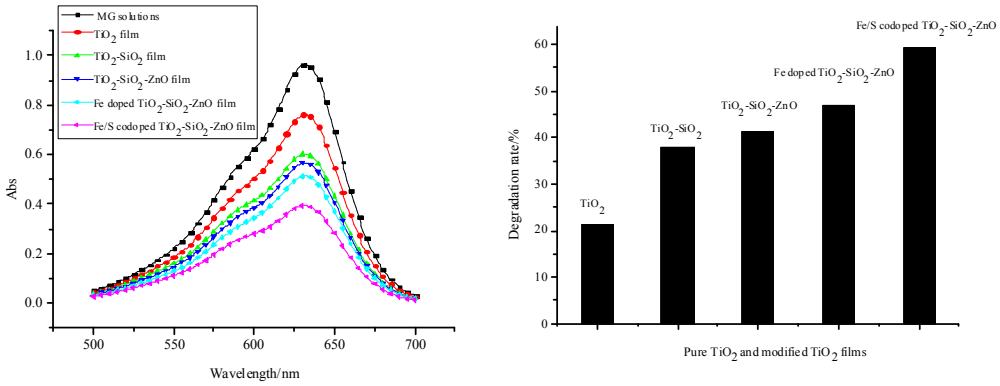
All sol-films were coated on the surface of a glass substrate by the controllable dip-coating device in the atmosphere. 5.0×10^{-3} mol dm^{-3} iron nitrate aqueous solutions or 5.0×10^{-3} mol dm^{-3} carbamide ($CS(NH_2)_2$) aqueous solutions was doped into the surface layer of TiO_2 gel-film, respectively. The surface doped TiO_2 composite films were calcined in air at a rate of 5℃/min up to 450℃ and were left to stay in the furnace for 1 h for organics removal.

The photodegradation activity of the photocatalyst was studied with TU-1901 UV-Vis spectrometer. The Brunauer-Emmett-Teller (BET) surface area of the TiO_2 powders was analyzed by nitrogen adsorption/desorption apparatus (ASAP 2020). UV-Vis diffuse reflectance spectra of the

film was recorded on a UV–Vis spectrophotometer with an integrating sphere accessory (IS19-1) using blank glass plate as a reference. The recombination of electron-hole in the sample was studied by the photoluminescence (PL) emission spectra, recorded at room temperature by a FLS 920 spectrometer with a 300-nm line of 450 W xenon lamp as excitation source.

Results and discussion

Methyl green (MG) is a recalcitrant organic dye. Figure 1 shows UV–Vis absorption spectra (a) and degradation rate (b) of MG solutions using pure TiO_2 film, TiO_2-SiO_2 film, TiO_2-SiO_2-ZnO film, Fe doped TiO_2-SiO_2-ZnO film and Fe/S codoped TiO_2-SiO_2-ZnO film on common glass substrates under UV-lamp irradiated with wavelength of 365 nm for 45 min. The degradation rates of pure TiO_2 film is 21%; TiO_2-SiO_2 film 38%; TiO_2-SiO_2-ZnO film 41%; Fe doped TiO_2-SiO_2-ZnO film 47%; and Fe/S codoped TiO_2-SiO_2-ZnO film 59%. Obviously, the Fe/S codoped TiO_2-SiO_2-ZnO composite photocatalysts in MG dye aqueous solutions exhibit highest photocatalytic activity in all samples.



(a) (b)

Fig.1. Absorption spectra (a) and degradation percentage (b) of MG solutions using pure TiO_2 and modified TiO_2 films on glass substrates after irradiated for 45 min

Figure 2 shows N_2 adsorption/desorption isotherms of the pure TiO_2, TiO_2-SiO_2, TiO_2-SiO_2-ZnO, and Fe/S codoped TiO_2-SiO_2-ZnO powders calcined at 450°C in air for 1.0 h. BET surface areas can be determined using nitrogen adsorption and desorption isotherms. From Fig. 2, the isotherms of the four samples exhibit hysteresis loops at high relative pressures from 0.4 to 0.8. It is evident that with the same relative pressure Fe/S codoped TiO_2-SiO_2-ZnO samples have highest adsorption quantities as well as highest surface area in all samples. In our case, the specific surface area of Fe/S codoped TiO_2-SiO_2-ZnO sample was determined to be 432.5 $m^2\ g^{-1}$, compared with pure TiO_2 103.4 $m^2\ g^{-1}$, TiO_2-SiO_2 388.1 $m^2\ g^{-1}$, and TiO_2-SiO_2-ZnO 413.8 $m^2\ g^{-1}$. The large specific surface area is favorable to the photocatalytic degradation, so the Fe/S codoped TiO_2-SiO_2-ZnO film exhibits highest photocatalytic activity in all samples.

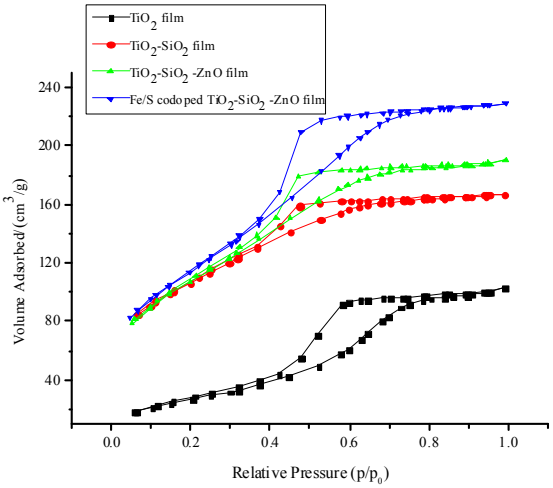


Fig. 2. N_2 adsorption/desorption isotherms of pure TiO_2 and modified TiO_2 samples

Photoluminescence emission is useful to understand the fate electron-hole pairs in semiconductor particles. The PL emission spectra of pure TiO_2, TiO_2-SiO_2, TiO_2-SiO_2-ZnO, and Fe/S codoped TiO_2-SiO_2-ZnO films are examined in the wavelength range of 325–500 nm in Figure 3. It shows that the position of the peaks about 375 nm due to the emission of the band gap transition is similar while PL intensities are different for three samples. The PL intensity of Fe/S codoped TiO_2-SiO_2-ZnO film is the lowest among all samples, indicating the recombination of electron and hole is effectively prohibited compared with other samples. Lowest recombination of electron and hole can result in highest photocatalytic activity of Fe/S codoped TiO_2-SiO_2-ZnO film.

UV–vis diffuse reflection spectra of pure TiO_2, TiO_2-SiO_2, TiO_2-SiO_2-ZnO, and Fe /S codoped TiO_2-SiO_2-ZnO films are shown in Figure 4. It can be seen that the absorbance onset of Fe /S codoped TiO_2-SiO_2-ZnO film red shift to more than 500nm. As a result, more photogenerated carriers can join in the degradation reaction; leading to enhance the photocatalytic activity of the multi-modified TiO_2 film. Considering the above discussion, the enhanced photocatalytic activity of the Fe/S codoped TiO_2-SiO_2-ZnO film is attributed to factors such as improved optical absorption property and improved lifetime of the charge carriers.

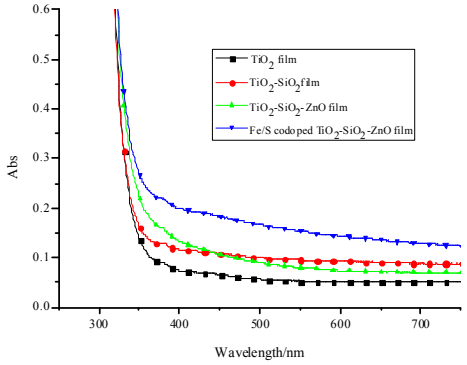

Fig. 3. Photoluminescence spectra of pure TiO_2 and modified TiO_2 films

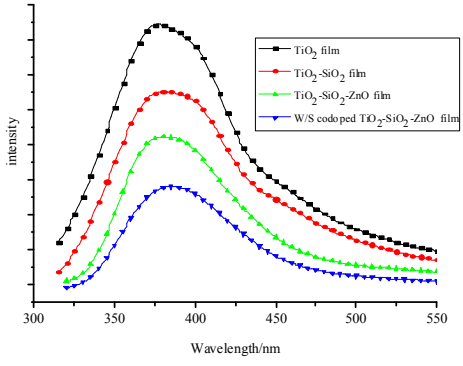

Fig. 4. Diffuse reflection UV-vis absorption spectra of pure TiO_2 and modified TiO_2 films

Conclusions

Fe and S codoped TiO_2-SiO_2-ZnO composite films were successfully prepared by composite semiconductor and metal or non-metal codoping in our experiment. Enhanced photocatalytic activity for the photodegradation of methyl green dye was observed for the modified TiO_2 composite film. In the system, obviously red shift and improved lifetime of the charge carriers may promise a potential application for TiO_2 film in visible light or solar light.

Keywords: polycarboxylate superplasticizer, density of carboxyl, fluidity of cement paste, concrete slump

Abstract. This study was undertaken to evaluate a new kind of polycarboxylate superplasticizer. Used polyoxyethylene ether (TPEG), acrylic acid (AA) as the monomer, ammonium persulfate (APS) as initiator, thioglycolic acid (TGA) as chain transfer agent, synthesised polycarboxylate superplasticizer with high water reducing rate. The effect of admixtures on fluidity and concrete slump were discussed in this paper. The structure of carboxylic acid water reducing agent was characterized by IR spectra and Gel permeation chromatography.This investigation also evaluated the influence of different serials of polyoxyethylene ether (TPEG), the dosage of acrylic acid (AA) and ammonium persulfate (APS).

Introduction

Polycarboxylate Superplasticizers are widely used in concrete today to increase the workability of fresh concrete as well as decrease the water requirement to achieve a given workability,they can reduce the hydration heat,increase the fluidity,lead to higher strength and better durability of the hardened products[1].

Polycarboxylate superplasticizers are considered the most potential category of polymeric dispersants. In terms of chemical structure,these polymers have lots of advantages: better fluidity and slump flow with low dosage of PCs, wide adaptability for cement,higher water-reducing efficiency,large freedom of molecular structure,more synthesis technology,more room for improvement[2-4]. The research and application of Polycarboxylate superplasticizers is just a decade. Researches focus on the choice of reaction monomer,synthesis temperature,initiator species,adjustment of process conditions,reduction of engineering cost and control of product prices,etc [5-6]. We have less understanding and cognition on relationship between PCs structure and dispertion properties,rheological properties and hydration theory as well as practical application in construction[7].

This paper had synthesized a series of polycarboxylate superplasticizaers in different pH .Different kinds of Isoamyl alcohol polyoxyethylene ether(TPEG) and different dosage of acrylic acid were used as monomer, ammonium persulfate (Aps) was used as initiator, TGA used as chain transfer agent. The influence of monomer type, carboxyl density , initiator dosage, chain transfer agent dosage and pH on dispersion property of superplasticizer was studied through the fluidity of cement paste and concrete slump flow .

Experimental

1.1 Chemicals and Equipment.

Prenyl alcohol ethoxylates (TPEG, Liaoning Kelong Chemical Co. LTD), Acrylic acid (AA,Wuhan Zhonghua Yongye Chemical Co. LTD), Ammonium persulfate (Aps, Shanghai degussa-aj chemical Co. LTD), Chain transfer agent (TGA, Changzhou Yurong Chemical Co.LTD)

,sodium hydroxide(NaOH),HuaXin cement,P.O42.5，WuGang II flyash,WuXin S95 silica fume. Cement paste mixer,NJ-160A,WuXi JianYi equipment Co. LTD ; Single horizontal-axis laboratory concrete mixer,HJW-60,ShenYang JuLin equipment Co. LTD.

1.2 Synthesis Process.

Put a flask within water and TPEG into water-bath heater, and stirried until the end of experiment; wait until TPEG dissolved, then add ed the APS at 60^{o}C, and dripped the AA and TGA solution; keep heating for certain hours, then decreased temperature; added the sodium hydroxide and water, and adjusted pH of the new product about 7; The new product would been gotten and its solid content was 40%.

1.3 Measurement.

The fluidity of cement slurry was tested according to Chinese Standard (GB/8077-2000).The water-cement ratio is 0.29,PCs dosage is 0.13%.

1.4 GPC Analysis method

The average of molecular mass and distribution of the new product was determined by gel permeation chromatography (GPC) using an Agilent-1100 chromatographic apparatus equipped with PL AQUAGEL-OH mixed 8μm, as well as a detector (Agilent-1100 VWD). The sample was analyzed using a 0.1mol/L of phosphate buffer solution. The standard material is PEG from UK Polymer lab

1.5 FT-IR Analysis method

The reaction product is distilled under reduced pressure，when the liquid is reduced to a certain extent,poured the solution into the beaker.It is precipitated,dissolved,washed and filtered by Isoropyl alcohol. Isoropyl alcohol is volatilized at 50℃,then dry to powder until constant weight at 85℃ .Presseed 1mg PCs and 100mg KBr into transparent sheet, wave at between 400-4000 cm^{-1} for 50 times.

Results and Discussion

2.1 Determination of monomer type

F108 and TJ-188 are synthesised by imported initiator, while F1088 and TJ-188C are synthesised by domestic initiator. The front two kinds of monomers are more active than back ones. The table shows F108 is more suitable for this method.

Table.1 Fluidity of cement paste with different monomer condition of PCs

Type	Fluidity of cement paste(mm)	Slump flow(mm)
F108(Liaoning Kelong Chemical Co. LTD)	260	230/560
F1088(Liaoning Kelong Chemical Co. LTD)	240	220/520
TJ188(ShangHai TaiJie Chemical Co. LTD)	250	230/540
TJ188C(ShangHai TaiJie Chemical Co. LTD)	235	225/515

2.2 Determination of carboxylic acid Dosage

Figures 1 and 2 are efforts of cement paste and concrete with different carboxylic acid dosage. We can see from the figures, with the carboxyl density increased from 1.5 to 3.8, the fluidity of cement paste increase gradually. When the carboxyl density exceeds 3.8, PCs are adsorbed to saturation on the surface of cement particles. While the carboxyl density increases, PCs absorb rapidly, it leads to slump loss of concrete. Less carboxyl density can cause poor adsorption capacity, PCs can't adsorb on the surface of cement particles effectively, the steric effects can't fully work, the fluidity of cement paste is small. When carboxyl density increases, the content of -COO- side chain increases, lead to more anionic charge density and larger electrostatic repulsion, add adsorption on cement particles, Dispersion performance was improved[8].

More carboxyl density caused higher adsorbtion ability , however, this decreases its branched chain density. The number of branched chain on the cement particle reduces, so its space steric hindrance weakens to some extent. Therefore the dispersion effect decreases. Figure 2 shows that the fluidity of cement paste can be achieved when carboxyl density is 3.8.

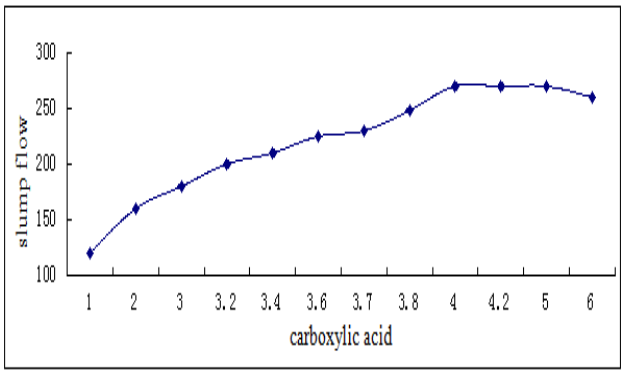

Fig.1 Fluidity of cement paste with different carboxylic

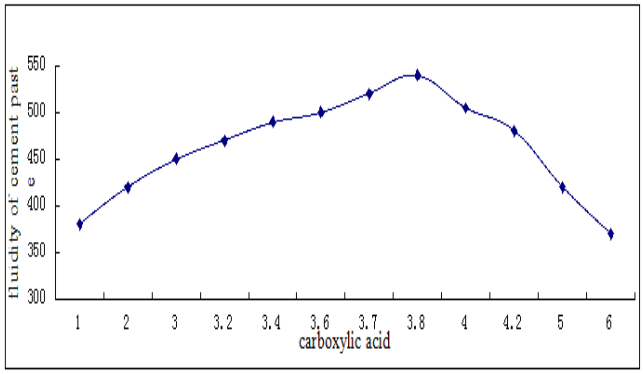

Fig.2 Slump flow with different density of carboxylic

2.3 Determination of initiator Dosage

We can see from figure 3 and 4, with all other conditions being equal, concrete has the best dispertion performance when the dosage of initiator is 0.35mol. This is because low dosage of initiator causes little active centre, reaction is not complete; as high dosage of initiator causes too many active centre, the molecular weight is too small to the disadvantage of space steric hindrance.

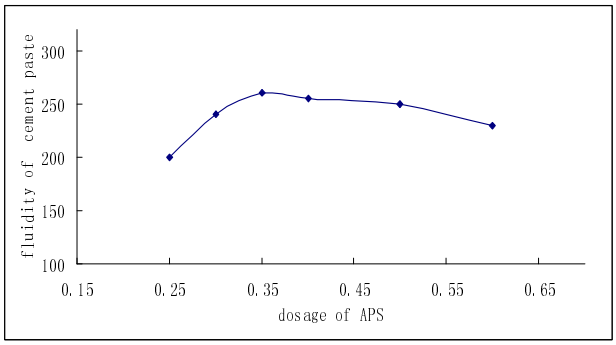

Fig.3 Fluidity of cement paste with different density of initiator

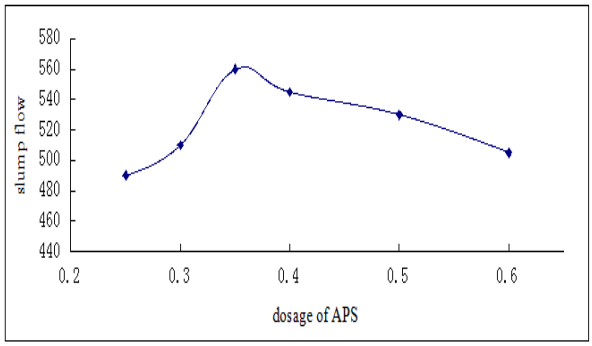

Fig.4 Slump flow with different density of initiator

2.4 pH effect on the performance of cement paste and concrete

We can conclude from Fig. 5 and 6, PCs impact little on the fluidity of cement paste and dispertion of concrete when pH changes between 3-9. Alkali aggregate reaction won't occur in this pH range.

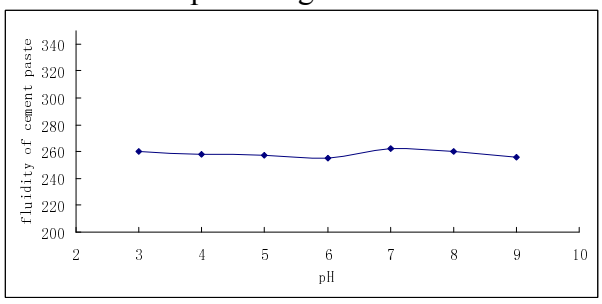

Figure 5.pH effect on the performance of cement paste

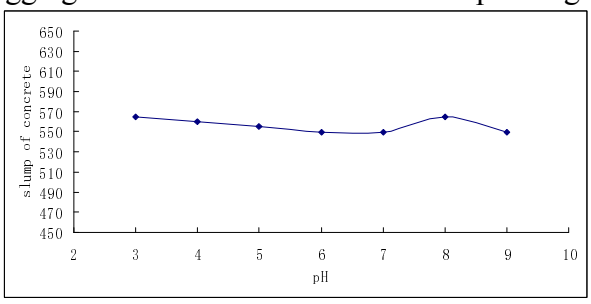

Figure 6.pH effect on the performance of concrete

2.5 GPC Analysis

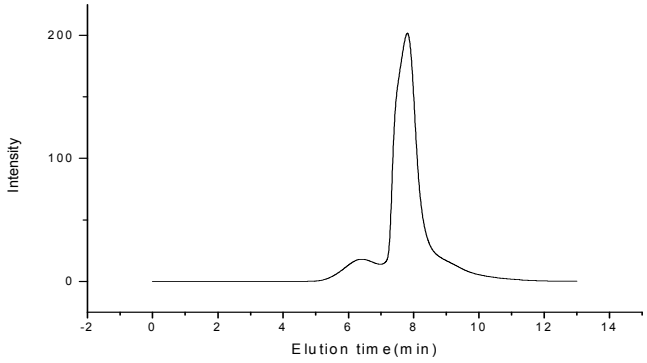

Fig.7 Molecular mass distribution of PCs

The molecular weight and distribution is an important element in evaluating the performance of PCs. High average molecular weight of PCs leads to higher absorption on the surface of cement .Higher molecular weight of PCs adsorb on the surface of cement particles preferentially; with its adsorption capacity on the surface of cement particles increase, the fluidity of concrete increases. The concrete can entrain large amount of air content if the molecular is too small, moreover, it causes faster slump loss and lower strength of concrete; The adsorption amount decreases when the molecular is large , it reduces the dispersion of concrete. Therefore, the best dispersion can be achieved when the molecular weight of PCs is within an appropriate range. Fig. 7 may have an intuitive understanding of its molecular weight distribution, it has narrow Fig. 7 may have an intuitive understanding of its molecular weight distribution, narrow molecular weight distribution of the molecular weight[9-10] .

2.6 FT-IR Analysis

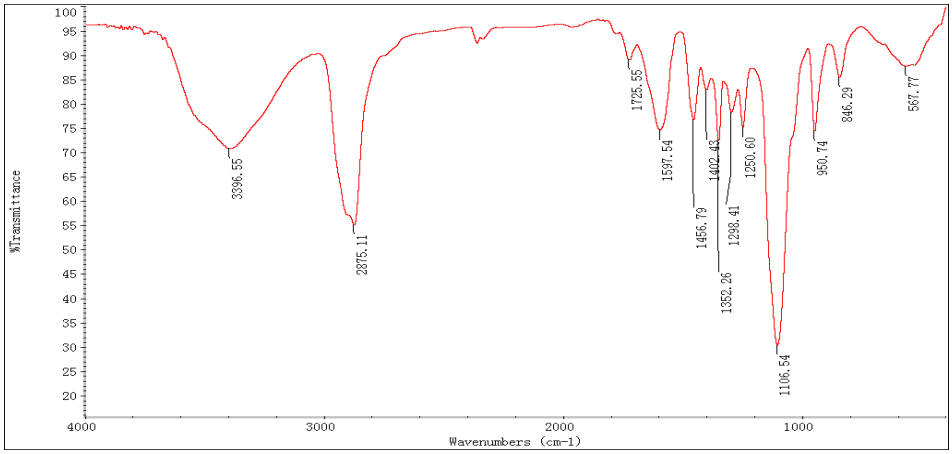

Fig. 8 IR of spectra of PCs

Fig. 8 shows that the wide peaks vary form 3350 cm^{-1} to 3400 cm^{-1} was due to the stretching vibration of O-H bond. The peaks at 2875 cm^{-1}, 1456 cm^{-1}, 1298 cm-1,1250 cm^{-1}, and 950cm^{-1} were the characteristic of absorption peaks of the polythethylene axide group (CH_2CH_2O). The typical absorption peak of the stretching vibration of C-O-C structure was detected at 1106 cm-1 and 1110 cm^{-1}. The characteristic of absorption peak of the COO- group appeared at 1725 cm^{-1} and 1456 cm^{-1}. And the absorption peak of the C=O in the ester bond was detected at 1725 cm^{-1}. It was declared that the sample was synthesized with different monomers which were referred to from Chapter 1.1 by IR analysis.

Conclusion

By discussing various factors that impact the performance of PCs, we confirm a suitable process conditions which a new type of polycarboxylate superplasticizer with high dispersibility was synthesized . The influencing factors of reaction include proportion of acid, initiator concentration, pH and additive. The fluidity of cement paste and slump flow of concrete can achieve 275mm and 570mm. It is possible to realize industrial production.

Keywords: Modification; Mannich reaction; amidation; esterification; superplasticizer; synthesize

Abstract. A new type of amide-modified polycarboxylate superplasticizer was synthesized by a two-step method: Firstly, a mixture of amidated and esterified products reacted by maleic anhydride and 2-aminoethanol was modified through Mannich reaction. Then, the modified product was reacted with Prenyl alcohol polyethenoxy ether (TPEG), acrylic acid and other monomers to obtain an amide-structured polycarboxylate superplasticizer. The molecular weight and molecular weight distribution were measured by Gel permeation chromatography (GPC). Lastly, the optimum AA to modified product ratio, initiator dosage and reaction time were determined by cement mortar test. The concrete application performance showed that the synthesized superplasticizer could improve the fluidity of the concrete and maintain the slump loss as well. The introduction of modified PCE has no harm for the concrete strength.

Introduction

Nowadays, superplasticizer has been an essential component in cement admixtures for the superior performance it endows to concrete or other cement materials. Among those superplasticizers, polycarboxylate-type (PCE) superplasticizer was most favored to industry due to its high water-reduction ratio and flexibility in chemical structural design [1]. The special chemical structure of PCE has the potential to be modified which can be easily designed to meet specific needs in various applications [2-6].

Researchers have already used the products reacted by maleic anhydride and 2-aminoethanol as the monomer to polymerize with other functional monomer to obtain PCE [7]. The main drawback for this method is that the inefficient use of the esterified product acquired from the amidation-esterification process as the performance of the PCE mostly relied on the amidated product. It has to be noted that even use highly efficient amidation catalyzer, high degree of amidation still can't be achieved.

In this study, in order to provide the PCE with better dispersion ability and to overcome the large time spans between the production of concrete and incorporation thereof which often leads to server slump loss[8], Mannich reaction was chosen to modify the esterified product with a functional monomer to give fully use of the amidation-esterification product. Then, the modified product (M) was polymerized with other monomers to obtain the modified PCE. The optimum condition for the polymerization was determined and the performance in concrete of the modified PCE was measured, in comparison with other samples, the modified PCE showed good dispersion and slump-retaining ability.

Materials and methods

Chemicals and materials. The maleic anhydride (MA), acrylic acid (AA), sodium hydrate, sodium methylacrylsufonate (SMAS), ammonium persulphate (APS) and thioglycollic acid (TGA) are all industrial grade. TPEG (M_n=2400) was obtained from. 2-aminoethanol, 4-dimethylaminopyridine (DMAP), functional monomer A, polyoxymethylene and propionic acid are all commercially available in analytical grade.

Modification of amidated and esterified products. At first, an amount of 2-aminoethanol was added to a 500ml four-necked flask equipped with a condenser and a stirring bar. Then, propionic acid was added to the flask to fully neutralize the solution and the mixture was heated to 60°C in water bath. Finally, MA and DMAP were added to the mixture to react for 2h and product was withdrawn from the reactor. The esterify ratio was measured as the given literature.

According to the obtained data, monomer A and polyoxymethylene were then added to the flask to react for 2 more hours under 80°C to give the modified product(M). Figure 1 was the general equation for the reaction:

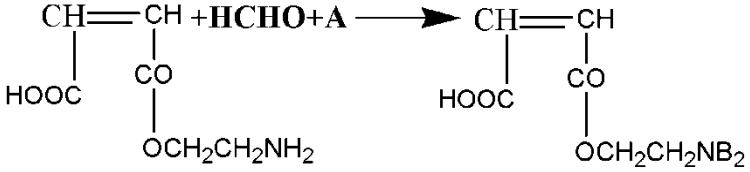

Fig.1 Reaction equation for modification

Synthesis of the modified PCE. An amount of M, AA, SMAS and TGA was mixed in water to give a 20wt% solution. 150g TEPG and water was added to a 500ml four-necked flask equipped with a condenser, a nitrogen inlet and a stirring bar afterwards and stirred for 15min to give a homogeneous solution. The solution was gently heated to 60°C and the monomer solution and APS solution(20%wt) was then added to the flask under a fixed feeding rate. After complete the feeding process, the mixture was stirred for several hours under the same temperature. At the end, the pH was adjusted to 7 with 30wt% NaOH and the PCE was acquired.

Measurements. Molecular weight of PCE was measured by gel permeation chromatography (GPC, Waters 150C, USA), using the solution of methanol and buffer solution (1/2, v/v) as the eluent. (Column, PL aquagel mix/m, 7.8*300 mm, Agilent1100, Agilent Company, USA). The buffer solution was $Na_2B_4O_7$/KCl aqueous solution (pH = 8). Narrow polyethylene glycol (PEG) was used as calibration standards. The GPC detector included the refractive index.

Test of the fluidity of cement pastes added with superplasticizer was under the Chinese National Standard (GB 8077-2000) "Methods for testing uniformity of concrete mixture" and the cement used for the test was HUAXIN P·O 42.5, the w/c ratio was 0.29 and the dosage of the PCE was 0.13% (by percent Weight based on solids cement).

Concrete performance was measured following the Chinese National Standard (GB 8077-2008) "Concrete admixtures" and the material proportion was shown in Table 1, the dosage for the PCE was 1.8%.

Table 1 Material proportion for the concrete test

Water (kg/m^3)	Cement (kg/m^3)	Fly ash (kg/m^3)	Slag (kg/m^3)	Sand (kg/m^3)	Gravel (kg/m^3)	PCE dosage (%)
155	210	90	80	760	1080	1.2

Results and discussion

Effect of AA to modified product (M) ratio on the property of the PCE. The AA to M's ratio directly affects the charge density on the polymer chain which determines the PCE's dispersion ability so it was discussed at first. The effect of AA to modified product (M) ratio on the fluidity of cement paste was shown on Figure 2.

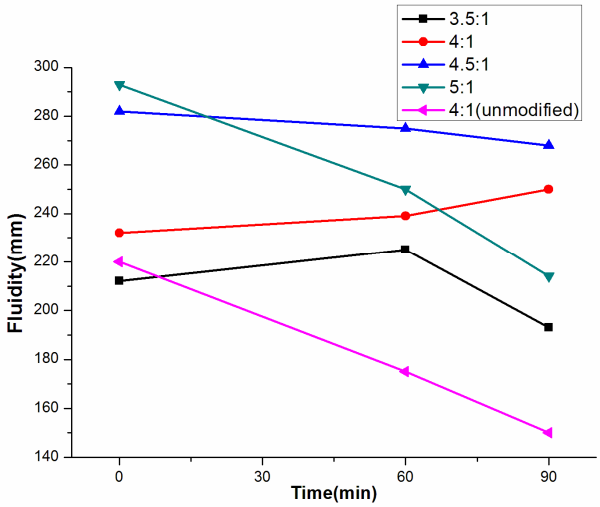

Fig. 2 Effect of the AA to M's ratio on the fluidity of cement pastes

According to Figure 2, the initial fluidity of the cement paste increase as the AA to M's ratio increase and it's obvious that PCE synthesized by M showed better dispersion ability. This is because the modified product can hydrolyze in alkaline environment and then provide better dispersion and fluidity retaining ability. When the ratio was 4.5:1, the PCE showed good initial fluidity and no slight lose on fluidity was observed within 1 hour. This means under this ratio, the charge distribution on the side chain of the PCE can reach a relatively optimum value, which can benefit the PCE's electrostatic repulsion of electric charges and the steric hindrance [9]. When the ratio above 4.5:1, the initial fluidity kept on increasing while obvious lose was taken place. This can be ascribed to two reasons: 1. The PCE can absorb faster under higher AA to M's ratio which will lead to fluidity lose caused by the hydration of the cement. 2. The number of amide group and the ester group will decrease as the increase of the AA to M's ratio which will affect its ability to retain fluidity.

Effect of the dosage of initiator on the property of the PCE. The effect of the dosage of initiator on the dispersing effectiveness of the PCE was shown in Figure 3.

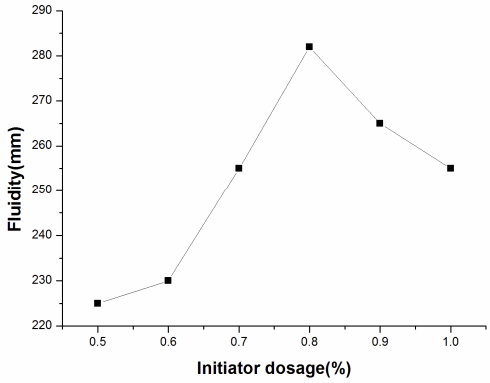

Fig. 3 Effect of the dosage of initiator on the fluidity of cement pastes

As shown in Figure 3, the fluidity increase as the initiator dosage increase and the best dosage for the initiator was 0.8wt% to all monomer. The fluidity of the cement paste decrease as the dosage exceed 0.8wt%. This is attributed to the higher molecular weight of the PCE synthesized under lower initiator concentration which has poor dispersion ability and the lower molecular weight of the PCE synthesized under higher initiator concentration which impedes the ability of steric hindrance[10].

Effect of the reaction time on the property of the PCE. Figure 4 presents the evolution of fluidity with reaction time for PCE synthesized under the AA to M's ratio was 4.5:1.

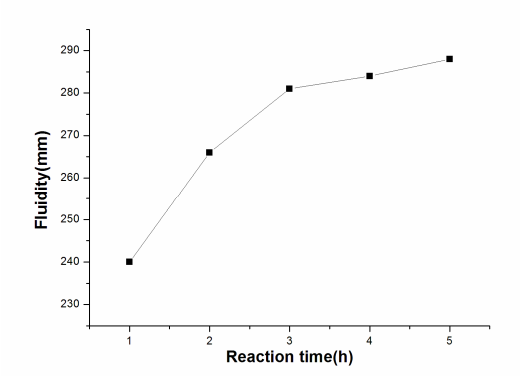

Fig. 4 Effect of the reaction time on the fluidity of cement pastes

The data suggests that the optimum reaction time for the polymerization was 3 hours which gives the PCE favorable dispersion ability. This is mainly due to the low reaction activity of the maleic anhydride and its derivants. If the reaction time is short, the monomer conversion will be affected thus will reduce the PCE's dispersion ability. If the reaction time is too long, no distinct improvement in dispersion ability can be seen. Considering the energy consuming cost and the efficiency, we selected 3 hours as the optimum reaction time.

Molecular weight and molecular weight distribution for the PCE. The plot of molecular weight and molecular weight distribution (MWD) of the modified PCE was shown in Table 3 and Figure 5.

Table 2 Molecular weight and its distribution for the modified PCE

sample	M_n (g/mol)	M_w (g/mol)	M_p (g/mol)	MWD
Modified PCE	35553.7	10928.2	16110.2	3.2

In Figure 5, despite a negative peak corresponded to solvent, only one sharp peak can be seen which indicates almost no unreacted monomer remained in the final product. On the other hand, it proves that the modified product has sufficient polymerization activity and capable of forming the amide-structural PCE.

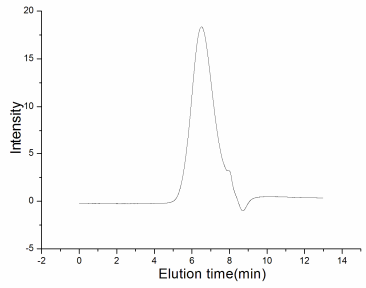

Fig. 5 Molecular weight and its distribution for the modified PCE

Concrete application test. For the better use of our modified PCE, concrete application test was utilized and the results were shown in Table 2.

Table 3 Application performance of modified PCE in concrete

sample	(slump/spread)/mm		Compressive strength (MPa)	
	Initial	1h	7d	28d
1	230/560	210/510	25.5	37.1
2	235/605	220/570	25.8	38.9
3	250/600	225/590	25.2	38.2

*Sample 1 is the conventional PCE supplied by our own admixture department, sample 2 is the modified PCE and sample 3 is the S-95 PCE supplied by Nippon Shokubai Co., Ltd.

From the table 2, the fresh concretes mixed with modified PCE and S-95 both exhibited a good slump and slump retention behavior under the same dosage. Our modified PCE has comparable initial dispersion ability to S-95 while a bit of worse in slump retention ability. At the same time, the adding of modified PCE has no harm to concrete's early strength while exhibits higher 28d strength. One of the reasons was our modified PCE has a notable complexation behavior, which endows the hydration products a more dense structure.

Conclusions

With AA to M's ratio of 4.5:1, initiator dosage at a dosage of 0.8wt% and the reaction time of 3 hours, a modified PCE with good flow property and slump retaining ability was successfully synthesized.

GPC measurement showed that the modified product had a desirable polymerization activity and no monomer residual was observed.

The concrete test accorded well with the cement pastes fluidity results. The modified PCE showed good dispersion and slump-retaining ability and may provide extra strength upon 28 days.

Abstract. A low carbon content and improved steel making practices have imparted advanced high strength steel (AHSS) CP800 with superior combination of strength, ductility and weldability. Its performance in fatigue, however, is not well understood. Stress-controlled high cycle fatigue (HCF) tests were conducted to obtain stress vs. fatigue life curve (S-N curve), and the fatigue limit of CP800. The follow HCF performances were obtained. $\sigma_{0.1} = 476MPa$, SRI1=1940MPa, b=-0.09972, $Nc_1=2.89\times10^6$, and $R^2= 0.88$. The collected material data are used as a basis of comparison of CP800 with more common grades of structural steel. CP800 steel shows high strength, comparable ductility, and high fatigue limit level. The test results indicate that compare to that of lower strength common grades of structural steels, CP800 steel has a much higher fatigue endurance limit (say, 476MPa), about 0.6 of its tensile strength (TS). Thus, provides a distinct advantage.

Introduction

Fatigue is the progressive and localized structural damage that occurs when a material is subjected to cyclic loading, the most important failure mode for mechanical components under cyclic loads, and problem for many types of structures. As the century progressed, more and more failures of components subjected to repeated loads were recorded. Today, structural fatigue has assumed an even greater importance as a result of the ever-increasing use of high-strength materials and the desire for higher performance from these materials [1-2].

Compared to conventional structural grade steels, CP800 provides superior strength, comparable ductility [3-4], as well as improved weldability [5]. The improved performance of CP800 is achieved through lower levels of carbon and other elements, in conjunction with advanced steel making practices. As a result of the improved performances of advanced high strength steel CP800, it is rapidly gaining popularity for use in car manufacturing. However, utilizing the benefits of CP800 with higher yield strength (say, higher than 680 MPa) may not be possible under current design standards because the fatigue limit state is likely to control the design [1]. Research on CP800 has mainly focused on mechanical properties and weldability [3-4]. Little attention has been paid to its fatigue properties. The work presented is aimed at investigate the fatigue properties of CP800 for component life prediction purpose. The fatigue performance of CP800 steel is compared to other grades of structural steels including TL1114, S500MC, and TRIP600-SH steel, commonly used in modern car structures.

Material and Experimenal

Material. The sheet steel investigated is CP800 with a thickness of 3.5mm. Its chemical composition in mass percent is 0.06C-1.71Mn-0.45Si-0.11Ti.

Test method and equipment. HCF tests were carried out on ZWICK-100KN HCF test machine. Using a stress ratio of 0.1(R= 0.1). HCF tests were done according to nation standard of China GB/T 3075-2008[6]. The specimen size of HCF test is presented in Fig.1, with a guage length of 42mm and width of 10.5mm. The specimen is parallel to the rolling direction of the sheet.

Fatigue strength is obtained with staircase test method. High-cycle fatigue data are usually presented as a plot of stress, S, versus the number of cycles to failure, N. A log scale is used for both of the stress and the number of cycles. Here afterward, the value of stress, S, is chosen to be the maximum stress, S_{max}. The fatigue life is the number of cycles to failure at a specified stress level, while the fatigue strength (also referred to as the endurance limit) is the stress below which failure does not occur. As the applied stress level is decreased, the number of cycles to failure increases.

S-N curve and parameter SRI1, b, N_{C1} is illustration in Fig.2. Here, SRI1 is the intercept of the diagonal line to Y axis, b is the slope of the diagonal line, and Nc_1 is fatigue life of the intersection point of two lines, the slope of the horizon line (b_2) is 0.

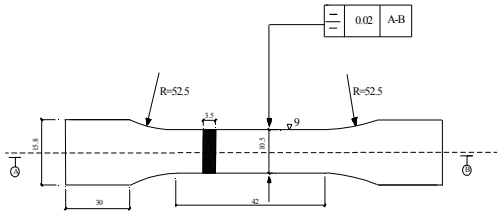

Fig. 1 Specimen of HCF test

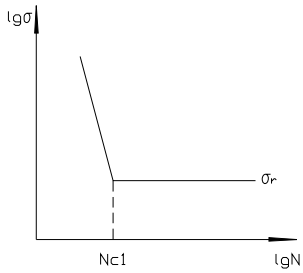

Fig. 2 S-N curve and HCF test parameters

Results and discussion.

HCF test data. Table 1 listed the HCF test data of steel CP800.

S-N curve. S-N curve drawn on the basis of HCF test data is shown in Fig. 3. From the linear regression of the diagonal curve on the S-N digram, parameters of fatigue characteristics such as SRI1, σ_r, N_{C1} and b were obtained as follow.

Table 1 High cycle fatigue test data of CP800 (R= 0.1)

Stress	N 10^5			N_{mean} 10^5
（MPa）	1	2	3	
600	0.82	0.87	1.09	0.93
560	1.55	1.73	2.72	2.00
520	3.56	6.58	9.86	6.67
480	10.2	11	100	40.40
440	100	100	100	100

Diagonal line:

$$Y=3.28771+(-0.09972)X$$

$$R^2 = 0.88335832$$

$$\lg(\sigma_{0.1}) = 3.28771 + (-0.09972)\lg N$$

Slope: b = - 0.09972

When: $\lg(\sigma_{0.1}) = 3.28771$

Intercept of the diagonal part of the curve to Y axis: SRI1=1940MPa

$$Nc_1 = 2.8886\times10^6$$

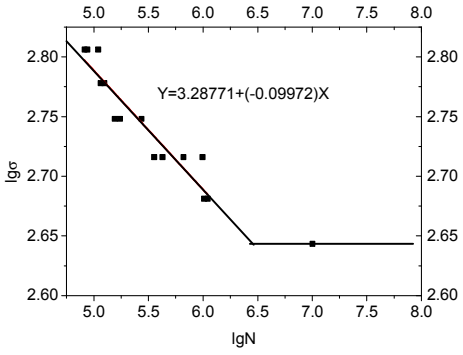
Thus, fatigue properties of CP800 of the diagonal line fit the following equation.

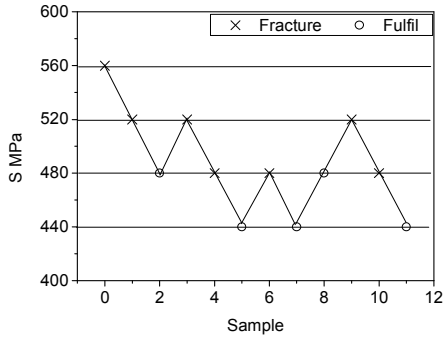
$$\sigma_{0.1} = 1940 - 0.09972\lg N$$

Test data drawn on the basis of staircase test results of CP800 in HCF test is shown in Fig. 4. So the fatigue strength of CP800 is obtained with the following calculation. The fatigue strength $\sigma_{0.1}$ at stress ratio 0.1 of CP800 is 476MPa.

$$\sigma_{0.1} = \frac{440\times3+480\times5+520\times2}{3+5+2} = 476$$

$$\sigma_{0.1} = 476MPa$$





$N_0=10^7$，ΔS=40MPa，×-fracture, O-runout

Fig. 3 S-N curve of steel CP800 Fig. 4 Stair case test results of CP800

Comparison of HCF properties of CP800 to other steels. The comparison of HCF properties of CP800 to other steels such as TL1114, TRIP600-SH and S500MC is listed in Table 2.

It is found that the fatigue strength $\sigma_{0.1}$ of steel CP800 is 476MPa, much larger than that of steel TL1114 and TRIP-SH[7], and also larger than S500MC[8]. It indicates that CP800 has much better HCF properties. Thus CP800 can be chosen to use in lightweight car application purpose.

For a large number of steels, there is a direct correlation between tensile strength and fatigue strength; generally, higher-tensile-strength steels have higher endurance limits. The endurance limit is normally in the range of 0.35 to 0.60 of the tensile strength (TS).

Table. 2 Comparison of high cycle fatigue properties of different steels

Steel	SRI1 /MPa	Slope b	Nc_1 $\times10^6$	$\sigma_{0.1}$ MPa
CP800	1940	-0.09972	2.89	476
S500MC	1613	-0.08933	2.03	471
TRIP600-SH	774	-0.0398	11.7	405
TL1114	1193	-0.06896	7.59	400

Microstructure and mechanical properties on fatigue performance. The microstructure appearance of longitudinal specimen of steel CP800 is shown in Fig. 5. It is clear that fine second phases uniformly distributed on the polygonal ferrite matrix.

The stress-strain curves of CP800 are shown in Fig. 6, showing a yield strength (YS) of 750MPa, tensile strength (TS) 800MPa and total elongation (TE) 17%. Homogeneous microstructure of CP800 is benefit to obtain good combination of strength, ductility and fatigue properties. This causes the steel has a high fatigue strength of 476MPa.

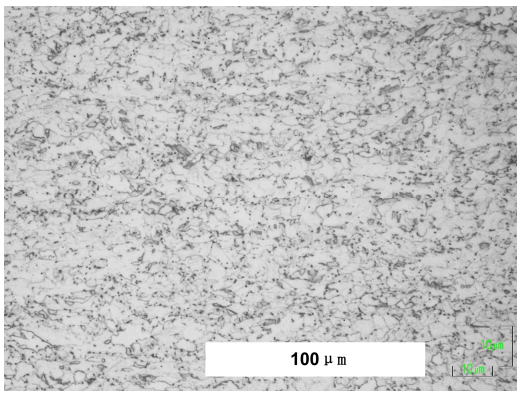


Fig. 5 Microstructure

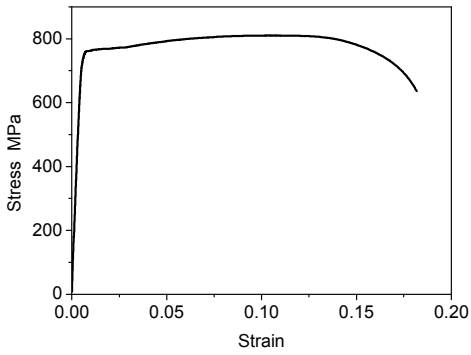

Fig. 6 Stress versus strain curve

Conclusions

The studied AHSS CP800 has a quite large fatigue strength of 476MPa at R=0.1, which is about 60% of its TS. Indicates that the studied steel CP800 has good fatigue property. The HCF performance of CP800 are listed as follow:

$\sigma_{0.1} = 1940 - 0.09972\lg N$

SRI1=1940MPa, b= - 0.09972, $N_{C1}= 2.89\times10^6$, R^2 = -0. 88335832

Keywords: nano Ag; PVDF; dielectric constant; energy storage density

Abstract. Conductive particle fillers could improve the dielectric properties of the polymer matrix. By solvent casting method, different volume fraction of nano silver particles were added into the PVDF film to prepare Ag/PVDF composite film so as to increase the dielectric properties of the materials. SEM was used to analyze the microstructure of the films. SEM images show that nano Ag filler particles were uniformly distributed throughout the whole matrix of the composite films. Dielectric property tests show that with the increase of nano Ag content, the dielectric constants of the composites increase first and decrease later while the dielectric losses decrease first and increase later. In the case of the optimal 17vol% Ag content, the dielectric constant of the composite film is the highest (14.5 at 100 Hz) with lower dielectric loss, and the energy storage density is relatively high (0.340 $J \cdot cm^{-3}$).

Introduction

Due to the excellent piezoelectric and dielectric properties, poly(vinylidene fluoride) (PVDF) and its copolymers have been studied widely over the last several decades [1,2]. There are several researches showing that the conductive metal (such as Pt, Pd, Ag, Al, Cu, Ni, Fe, and carbon nano tube [3]) and metal halide fillers ($BiCl_3$ [4], NaCl [5], $CuCl_2$ [6], LiCl [7]) could modify significantly the structure and physical properties of the polymer matrix, such as PVDF.

Adding of a small amount of conductive particles to the polymer matrix could effectively increase the dielectric constant of the substrate, and low content conductive particles/polymer matrix composite film can maintain good mechanical properties. In the present paper, nano Ag particles (diameter d=50 nm) was chosen as the conductive material, and Ag/PVDF two-phase composite films were prepared. By SEM analysis and dielectric property tests, the optimum nano Ag powder adding amount will be obtained. According to the literatures, percolation threshold of nano silver powder is about 17vol%. Therefore, in the paper, the contents of added nano-Ag powder are 15vol%, 16vol%, 17vol%, and 18vol%, so as to get the appropriate amount of nano-Ag powder.

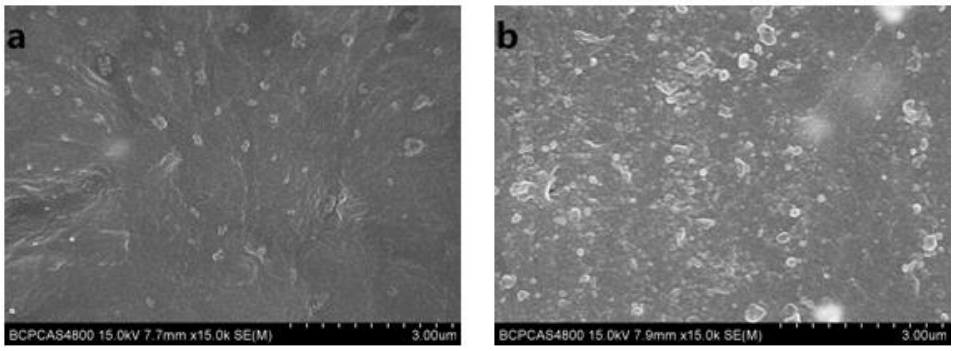
Experiment

PVDF films doped with different amounts of nano Ag as filler were prepared by solvent casting method. Nano Ag powder was purchased from Beijing DK Nano Technology Co., Ltd., China, and PVDF, Shanghai 3F New Material Co., Ltd., China. The PVDF powder and different volume fraction of Ag filler, which were 15vol%, 16vol%, 17vol%, and 18vol% respectively, were dissolved in dimethylformamide (DMF) respectively, stirred for 30 min, then Ag solutions were added into PVDF solution with an appropriate velocity, stirred for 6 h to form the uniform mixtures. The mixtures were cast on glass dishes and kept in vacuum oven at 70 ℃ for 20 h to remove the solvent completely.

The surface morphology was measured by a Scanning Electron Microscope (BACPC S-4800, Hitachi, Japan). The dielectric properties of the films were measured by an impedance analyzer (HP4192A, NOVOCONTROL GmbH, Germany). The electrical strength measurement was performed on CS2671A (Nanjing Changsheng Instrument Co., Ltd., China).

Results and Discussion

Scanning Electron Microscope (SEM). Fig.1 shows the surface morphology of the PVDF films doped with different fraction of Ag particles. It can be found that Ag particles are uniformly distributed throughout the PVDF matrix. When the volume fraction of nano Ag is 16%, inter-particle spacing is big with sparse particle distribution; While in the case of 17vol% of Ag, the inter-particle spacing is small and the film surface becomes rough with some small aggregation.



(a) 16 vol%-Ag/PVDF (b) 17 vol%-Ag/PVDF

Fig.1 SEM images of Ag/PVDF composite films

Dielectric Properties. The appropriate amount of nano silver can not only achieve good dielectric properties, but also keep good mechanical properties of polymer matrix. According to percolation theory, for conductive particles/polymer composites, when the content of particles is close to the percolation threshold, the dielectric properties will change exponentially. Therefore, nano Ag/PVDF composite films with 15vol%, 16vol%, 17vol%, and 18vol% Ag were prepared to determine the appropriate amount of silver. Fig.2 shows the dielectric properties of Ag/PVDF composite films with frequency.

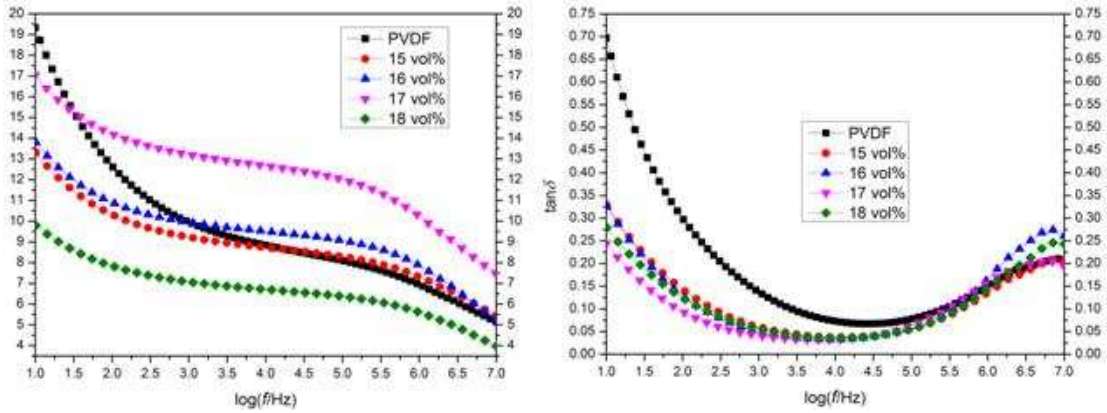


Fig.2 Frequency dependence of dielectric properties of Ag/PVDF composite films at room temperature

As can be seen from Fig.2, the change of dielectric constant of composite film with frequency is diffrent from that of pure PVDF. Dielectric constant decreased with increasing frequency more slowly, and the change of dielectric constants is the same for diffrent Ag contents, namely decreased with increasing frequency. At the same time, compared with pure PVDF, the change of dielectric constants is also different with different amounts of nano Ag added. When the amount of Ag is little or much, the dielectric constants of composites are lower than that of pure PVDF, while for addition amount of 17 vol% nano Ag, the dielectric constant of the composite is maximum. When the amount of nano Ag powder is less than 17 vol%, at the same frequency, dielectric constant increases with the increase of Ag nanoparticles, while the dielectric constant rapidly decreases when Ag content is greater than 17vol%.

From Fig.2 it could be seen that dielectric losses of all Ag/PVDF composite films are less than that of pure PVDF over a wide frequency range (10–10^6 Hz), and increase first and decrease later with the

increase of frequency. The lowest loss is about 0.05 at the frequency of 10 kHz. And there are little differences among the losses of composites with different Ag content. At the frequency range of 10–10^4 Hz, when the amount of nano Ag powder added is less than 17vol%, the loss of Ag/PVDF composites decreased with increasing Ag powder; And when the frequency is greater than 10 kHz, the losses of the films are the same.

Optimal Ag Content. According to percolation theory, in the conductive particle/polymer composite system, when the conductive filler content is close to the percolation threshold, the electrical performance will change abruptly, such as the dielectric constant. Accordingly, to determine the appropriate amount of Ag nanoparticles, Ag/PVDF composites with different Ag content were prepared. Fig.3 compares the dielectric properties nano Ag/PVDF composite films with 15vol%, 16vol%, 17vol%, and 18vol% Ag at 100 Hz.

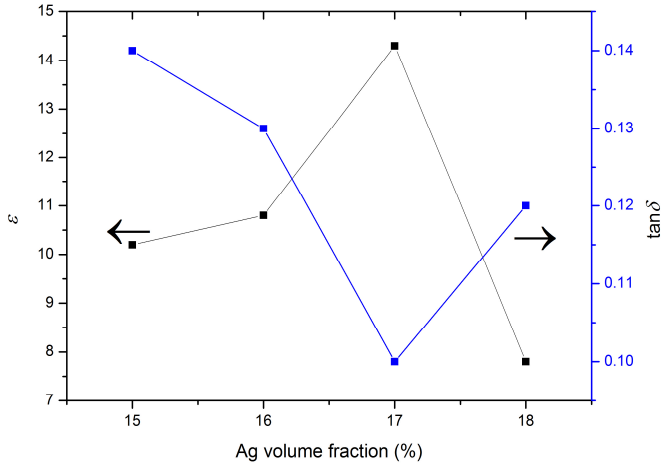

Fig.3 Dielectric properties of Ag/PVDF composite films with Ag content at 100 Hz

Fig.3 shows that with increasing the amount of Ag nanoparticles, the dielectric constant of Ag/PVDF composite films increase first and decrease later while dielectric loss being opposite; When the content of Ag nanoparticles was 17vol%, the dielectric constant reaches the highest while dielectric loss the lowest. Thus, it is determined during the experiment that 17vol% is the optimum content of nano Ag powder.

Dielectric Strength and Energy Storagy Density. Table 1 gives the dielectric strength of Ag/PVDF composite files with different Ag content. According to Fig.2, dielectric constants of 15vol%–18vol% Ag/PVDF at 100 Hz are 10.3, 10.5, 14.5, and 7.8 respectively. By the following equation $W = \frac{1}{2}\varepsilon_0 \varepsilon E_{bd}^2$ (W, ε_0, ε, and E_{bd} are energy storagy density, vacuum dielectric conatant, dielectric conatant, and breakdown voltage respectively), energy storagy density of Ag/PVDF films could be calculated shown in Table 1.

Table 1 Dielectric strength and energy storagy density of Ag/PVDF films at 100 Hz

Content of Ag	Breakdown voltage [kV]	Thickness [mm]	Dielectric strength [kV·mm^{-1}]	Energy storagy density [J·cm^{-3}]
15 vol% Ag	3.68	0.0398	92.46	0.389
16 vol% Ag	3.52	0.0434	81.11	0.305
17 vol% Ag	4.44	0.0610	72.79	0.340
18 vol% Ag	3.81	0.0644	59.16	0.121

It can be seen from Table 1 that with the increase of Ag content, although the dielectric constant increased to some degree, the dielectric strength and the energy storage density decreased. In the case of the optimal Ag content 17 vol%, the dielectric constant is the highest (14.5) and the energy storage density is relatively high (0.340 J·cm^{-3}).

Conclusion

Conductive particle/polymer composites nano Ag/PVDF were prepared with Ag volumme content of 15%, 16%, 17%, and 18% according to percolation theory. The microstructure analysis and dielectric property tests were performed. SEM images show that filler particles nano Ag were uniformly distributed throughout the whole matrix of the composite films. Dielectric property nanalysis show that with the increase of Ag content, the dielectric constants of the composites increase first and decrease later while the dielectric losses decrease first and increase later. In the case of 17vol% Ag content, the dielectric constant of the composite is the highest (14.5 at 100 Hz) with lower loss, and the energy storage density is relatively high (0.340 $J \cdot cm^{-3}$).

Keywords: Laser cladding; High entropy alloy coating; Wear; Magnesium alloy

Abstract: To improve the wear properties of AZ91D magnesium alloys, a $Cu_{0.9}NiAlCoCrFe$ high entropy alloy (HEA) coating was fabricated on AZ91D magnesium alloys by laser cladding using prealloyed $Cu_{0.9}NiAlCoCrFe$ powders. The microstructure of the HEA coating was characterized by OM, SEM and XRD. The wear resistance of the HEA coating was evaluated under dry sliding wear test condition at room temperature. The results show that the HEA coating mainly consists of a simple BCC solid solution phase. The HEA coating exhibits excellent wear resistance. The main wear mechanisms of the HEA coating and the AZ91D substrate were different, the former dominated by oxidative abrasive wear and the latter suffered from both adhesive and abrasive wear.

1. Introduction

High entropy alloys (HEAs) including at least five principal elements in equimolar or near-equimolar ratios were reported by Yeh in 1995 for the first time. Literatures had shown that HEAs formed simple body center cubic (BCC) and/or face center cubic (FCC) solid-solution phases identified by X-ray diffraction (XRD) patterns [1-2]. HEAs exhibites many advantages in application such as high wear resistance [1-2], excellent corrosion resistance [3], outstanding oxidation resistance [4], low electrical and thermal conductivity and low coefficient of thermal expansion [5]. The microstructure characteristic of HEAs results in four main effects including high entropy, severe lattice distortion, sluggish diffusion and cocktail effect [2], which is different from conventional alloys such as Fe, Al, Cu, Ti, Mg, Ni-based alloys and intermetallic compounds such as Ti-Al, Ni-Al, and Fe-Al.

Up to date, plenty of technologies, for instance, vacuum arc melting[1], hard surface welding (tungsten inert gas (TIG)[6] and gas tungsten arc welding (GTAW)[7]), mechanical alloying[8], thin-film coating deposition (reactive DC sputtering)[9], thermal spray [4], and laser cladding [10-13] have been applied to produce HEAs or high-entropy alloy coatings. Among these technologies, laser cladding has attracted growing interest in recent years because of its advantages such as fast heating and cooling, uniform and dense cladding, and low dilution [12, 13]. Researchers mainly focused on microstructures and properties of laser cladding coatings on Ti-6Al-4V [10] and carbon steel [11-13]. However, it's very difficult to obtain good quality laser-clad coatings fabricated on pure magnesium substrate [14,15] as a result of the low melting and boiling point of magnesium. Consequently, few literatures were reported.

Magnesium alloys are widely used in many fields such as automotive, communication, electron, and aerospace. However, low surface hardness and poor corrosion resistance have hindered its widespread. A number of surface modification techniques, for example, electrochemical plating, conversion coating, anodizing, gas-phase deposition process and organic coating, have been used to improve its wear and corrosion resistance. However, all these techniques have their own drawbacks and are not able to fulfill the goal mentioned above. Thus, it's very urgent to develop a better, simpler and cheaper coating technology on magnesium substrate.

Surface engineering technique, namely laser cladding, has drawn considerable attention in recent years for the enhancement of the wear resistance and corrosion properties of magnesium alloys[16]. For example, Zr-based amorphous composite coatings were fabricated on pure magnesium substrate successfully by laser cladding to improve property. Furthermore, this kind of coating also has promising application in various industries owing to amorphous phase with high corrosion resistance and nano-crystalline and/or microcrystalline with eminent wear resistance [16]. To the best of our knowledge, no literature has reported the $Cu_{0.9}$NiAlCoCrFe high-entropy alloy coating fabricated by laser cladding on AZ91D magnesium alloys.

In this paper, a $Cu_{0.9}$NiAlCoCrFe high-entropy alloy coating on AZ91D magnesium alloys was fabricated by laser cladding. What's more, microstructures and wear behaviors of the coating were studied in this study.

2. Experimental methods and materials

The prealloyed $Cu_{0.9}$NiAlCoCrFe powder was prepared by argon gas atomization of the $Cu_{0.9}$NiAlCoCrFe melt, which was produced by using elemental metals (Cu 99.9%, Ni 99.95%, Al 99.8%, Co 99.95%, Cr 99.8% and Fe 99.9%). Particle size and purity of the prealloyed $Cu_{0.9}$NiAlCoCrFe powder were 48-75μm and 99 wt.%, respectively. Laser cladding of the prealloyed $Cu_{0.9}$NiAlCoCrFe powder was conducted approximately 1mm thick on AZ91D magnesium alloys with the size of 100mm×50mm×10mm by pasting binder. Afterwards, a high power Rofin TR050 CO_2 laser was employed to track melting under the 99.999% Ar-shielding atmosphere. The laser spot diameter and laser power were kept constant at 4mm and 3000W, respectively, and laser scanning velocity of 10mm/s and 25% track overlapping condition was adopted.

Phases of the coating were determined by an X-ray diffraction (XRD) with Cu-K_α radiation at 40 kV and 30mA (X' Pert PRO). Microstructure of the cross-section coatings etched by alcohol solution with 4% of nitric acid (volume fraction) and etched by aqua regia solution was examined by an Axiovert 200MAT optical microscope (OM) and a Quanta 400 scanning electron microscope (SEM) with an energy dispersive X-ray spectroscopy (EDS), respectively. A micro-hardness tester (MICROMET 3) using a test load of 100g and a load-well time of 15s was employed to measure the microhardness of the cross-section coating.

The dry sliding wear resistance of the HEA coating was evaluated using a block-on-ring dry sliding wear tester at room temperature. The cladded specimens for the wear test were cube blocks with dimensions of 10mm×10mm×10mm, which were slid against a rotating ring of hardened bearing steel AISI52100 (Fe-1.0C-1.5Cr-0.25Si-3.0Mn) with a hardness of 60HRC ($HV_{0.1}$700). The test load used was 98N. The relative sliding speed was at 0.4187m/s. The wear test cycle lasted for 75min and the corresponding total wear sliding distance was 1884 m. The as-received AZ91D magnesium alloys was selected as the reference materials for all wear tests. Each test was repeated three times. The wear weight loss was measured using an electronic balance (Bartorius BS110) with an accuracy of 0.1mg.The surface morphologies of the worn specimens were examined by a Quanta 400 SEM with an EDS.

3 Results and Discussion

3.1 Microstructure

Figure 1(a) shows the OM image of the $Cu_{0.9}$NiAlCoCrFe high-entropy alloy coating on AZ91D magnesium alloys. The interface between the laser-clad high-entropy alloy coating and the AZ91D substrate is in good condition, indicating an excellent metallurgical bonding between the laser-clad coating and the substrate. Furthermore, it is found in Figure 1(b) that the coating has a fine microstructure with many small long rod-shaped patterns, which may be explained that heating and cooling effect during laser cladding is too fast for them to grow up. Table 1 is the EDS results of the $Cu_{0.9}$NiAlCoCrFe HEA coating. The results show that the chemical compositions of different positions are not close to the designed compositions and copper segregation of different degrees were observed in intragranular (position 2) and in intergranular (positions 1,3 and 4). That is to say, Cu element is easy to segregate in the Cu-Ni-Al-Co-Cr-Fe HEA system and this phenomena was proved by many researchers[15,17-18].

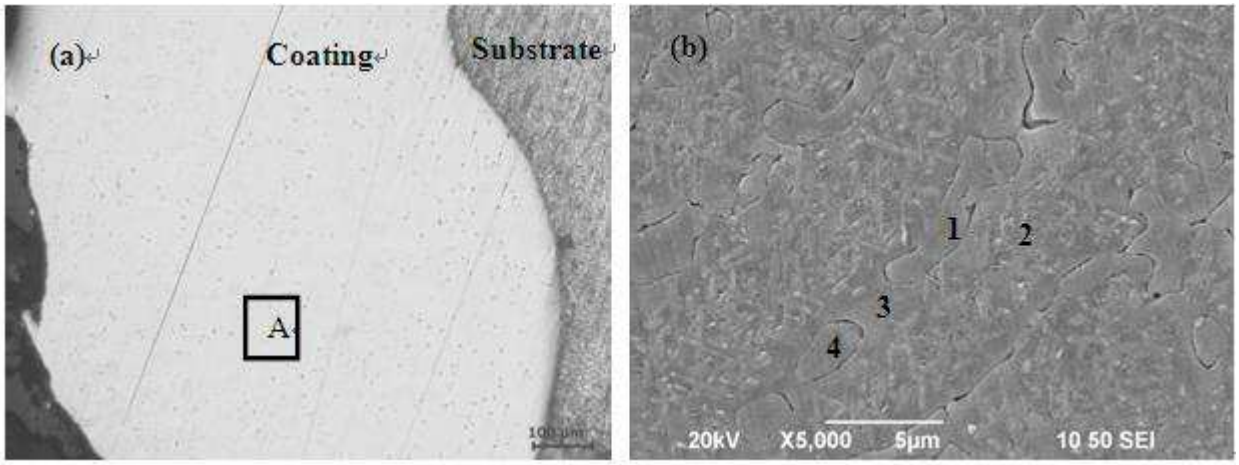

Fig.1 The morphologies of the laser-clad $Cu_{0.9}NiAlCoCrFe$ HEA coating: (a)OM image,(b)SEM image in area A.

Table 1 EDS results of the laser-clad HEA coating (wt.%)

Element	Al	Cr	Fe	Co	Ni	Cu
Point 1	6.01	8.79	12.03	11.98	14.70	46.49
Point 2	8.78	13.47	17.72	20.13	17.83	22.07
Point 3	8.94	12.65	16.05	17.70	19.34	25.32
Point 4	7.81	11.54	14.32	14.87	18.32	33.14
Raw powders	8.54	17.26	18.18	19.47	18.34	18.21

According to the Gibbs free energy formula: $G_{mix}=H_{mix}-TS_{mix}$, the higher mixing entropy, the lower system free energy. Thus, it is not strange that when segregation is smaller in the alloy because the solid solution is easier to form compared with the intermetallic compounds or the other ordered phase. Based on the data of reference [19], the enthalpy the Cu and Ni, Cu and Al, Cu and Co, Cu and Cr, Cu and Fe, Ni and Al, Ni and Co, Ni and Cr, Ni and Fe, Al and Co, Al and Cr, Al and Fe, Co and Cr, Co and Fe, Cr and Fe mixture are +4 kJ/mol,-1 kJ/mol,+6 kJ/mol,+12 kJ/mol,+13 kJ/mol,-22 kJ/mol,0 kJ/mol,-7 kJ/mol,-2 kJ/mol,-19 kJ/mol,-10 kJ/mol,-11 kJ/mol,-4 kJ/mol,-1 kJ/mol and -1 kJ/mol, respectively. Therefore, the mixing entropy in Cu-Ni, Cu-Co, Cu-Cr and Cu-Fe is insufficient to balance the huge mixing enthalpy between them. Thus, Ni, Co, Cr and Fe would seriously prevent the existence of Cu, and Cu (positions 1,2,3 and 4) appeared segregation.

Analytical results of XRD (Figure 2) confirmed that the laser-clad coating is a simple BCC solid solution. The results also prove that a laser-clad $Cu_{0.9}NiAlCoCrFe$ high-entropy alloy coating is successfully fabricated on AZ91D magnesium alloys by laser cladding. The formation of simple solid solution is attributed to the high mixing entropy. According to Boltzmann's hypothesis, high mixing entropy of solid solution with multi-principal elements will lower the tendency of ordering and segregation [20]. For the alloy $Cu_{0.9}NiAlCoCrFe$ in the experiments, its mixing entropy $\Delta Sm=Rln(n)=Rln6=1.79R$, (R: gas constant; n: the number of elements), is much higher than the formation entropy of intermetallic compounds or ordered phases. Thus, $Cu_{0.9}NiAlCoCrFe$ multi-element alloy is more likely to form solid solution rather than intermetallic or ordered phases.

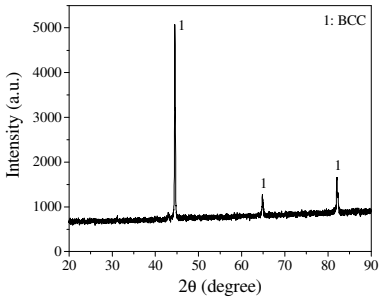

Fig.2 XRD patterns of the laser -clad HEA coating

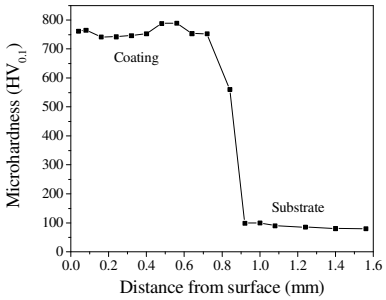

Fig.3 Microhardness of the laser -clad HEA coating

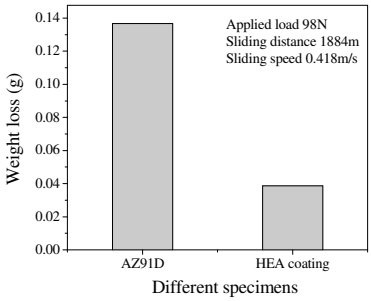

Fig.4 Weight loss of different specimens

3.2 Microhardness

Figure 3 presents the microhardness of the $Cu_{0.9}$NiAlCoCrFe HEA coating as a function of distance from the laser-clad surface. The results indicate that the microhardness of the HEA coating was about 7 times higher than that of the AZ91D substrate, and is bigger than that of the CuNiAlCoCrFe HEA (HV420) and the $Cu_{0.5}$NiAlCoCrFe HEA (HV458) [17], which were fabricated by cast process. The reason is that, under the effect of rapid heating and rapid cooling of the laser beam, the microstructure became very fine and is benefical to improve the microhardness of the HEA coating due to the fine-grained strengthening effect. In addition, the differences among atomic sizes (Table 2) of elements makes the lattice distortion more severe, which also enhance the solid-solution strengthening effect. The high microhardness of the coating will be beneficial to improve the wear properties of the HEA coating.

Table 2 Atomic sizes of different elements

Element	Al	Cr	Fe	Co	Ni	Cu
Atomic size (nm)	0.143	0.125	0.124	0.125	0.125	0.128

3.3 Wear resistance

Figure 4 shows the wear test weight loss results of the laser-clad $Cu_{0.9}$NiAlCoCrFe HEA coating specimen and the uncoated AZ91D specimen under dry sliding wear test condition at room temperature. The results show that the wear resistance of the laser-clad $Cu_{0.9}$NiAlCoCrFe HEA coating was superior to that of the AZ91D substrate, and the weight loss of the former was about three times less than that of the latter. The wear-resistance results of different specimens are consistent with the corresponding microhardnesses of different specimens (Figure 3), and the higher microhardness, the better wear resistance.

A study of the worn surfaces of these two specimens showed that both surfaces displayed a plough-shaped appearance with fairly long continuous grooves. This indicates that the laser-clad $Cu_{0.9}$NiAlCoCrFe HEA coating can be deformed plastically and can keep up with plastic strains. The study also showed that the uncoated AZ91D specimen suffered from abrasive wear as well as adhesive wear. The latter is proved by the features of some elongated pockmarks (Figure 5a). In addition, microcracks had developed at the heavily deformed edges. A combined action of abrasive and adhesive wear together with edge cracking had caused a high wear rate (30.38μg/s). On the other hand, the dominant wear mechanism of the laser-clad specimen was oxidative abrasive. This is proved by the clear furrows with a great amount of wear oxide debris (Figure 5b). The results of EDS analysis (Table 3) of the worn surfaces showed that most of the wear debris was iron oxides mixed with elements of the laser-clad $Cu_{0.9}$NiAlCoCrFe HEA. According to Figure 3, the microhardness of the HEA coating is higher than that of the steel ring tool, thus, the steel ring tool material could be sheared off, and the wear debris would be smeared over the coated surface. Of course, sliding actions would cause the worn-off Fe debris suffered elevated temperature oxidation and formed iron oxides with the laser-clad $Cu_{0.9}$NiAlCoCrFe HEA under the dry wear test condition. This oxide debris would act as abrasive and resulted in the damage of the laser-clad $Cu_{0.9}$NiAlCoCrFe HEA coating. However, considering that a three-body wear mechanism was taking effect, a low wear rate of 8.58μg/s was obtained. As for the uncoated AZ91D specimen, only a small quantity of Fe oxide particles were detected on the worn surface (Figure 5a and Table 3) because its microhardness is lower than that of the test ring material.

Table 3 EDS results of the worn surfaces of the uncoated AZ91D and the laser-clad specimen (wt. %)

Samples	Position	C	O	Mg	Al	Zn	Fe	Ni	Cu	Cr	Co	Mn

5. Conclusions

(1) A high wear resistant $Cu_{0.9}$NiAlCoCrFe HEA coating can be fabricated on AZ91D magnesium alloys by laser cladding using prealloyed $Cu_{0.9}$NiAlCoCrFe powders.The coating mainly consists of a simple BBC solid-solution phase.

(2) Under dry sliding wear conditions, the wear resistance of the laser-clad $Cu_{0.9}$NiAlCoCrFe HEA coating was considerably higher than that of the uncoated AZ91D magnesium alloys, and the weight loss of the latter was about three times higher than that of the former. The main wear mechanism of the HEA coating was dominated by oxidative abrasive wear.

email: sdujy@163.com

Keywords: Laser plasma; Optical emission

Abstract. Plasma emission spectroscopy was used to study the evolution behavior of the Zn ions in the plasma produced by nanosecond pulsed laser beam irradiating on pure zinc metal targets. The measurements indicated that the hotter and denser region in the plasma was located at about 0.75mm from target surface and presented at delay time 250 ns with respect to the laser pulse. Compared to Zn atoms in the plasma expansion, the results reveal that Zn ions are characterized by weaker intensity in spatial profiles and shorter lifetime in temporal evolution, while, much higher brightness of Zn ions can been observed in early-state plasma emission.

Introduction

Pulsed-laser ablated plasma emission spectroscopy (PLAPES) has long been used as a very promising technique for real-time detection of multiple elements and determining the composition of materials in any physical state, including solids, liquids and aerosols [1-4]. Moreover, the deposition parameters of high quality films prepared using pulsed laser deposition (PLD) method can also be effectively controlled by PLAES [2-6]. Despite its versatility and wide applicability, however, it is well known that the plasma emission spectroscopy is not sensitive to accuracy, precision, limit of detection, etc., compared to some other established methods of chemical analysis.

The improvement of these applications has been proposed at the region of higher temperature and density plasma, which is highly related to the ablation process, the aerosol transport and the vaporization, atomization and ionization within the plasma. The enhancement of spectral lines, especially the spectral emission from multi-charged ions can be obtained at this region [4-6]. Recently, detailed characterization of ions in plasma by laser beam ablated metal has been provided to give very important and useful information for improving the analytical sensitivity and capability of PLAPES [3-7].

In this paper, we used plasma emission spectroscopy method to study the spatial and temporal evolution of Zn atoms and ions at the hot and dense region in the plasma by the interaction of a high intensity laser beam with the pure zinc metal. This suitable region can be deduced on the basis evolution of plasma parameters (electron temperature and density). The aim of the present work is to investigate the distinctions in intensities of spectra lines from atoms and ions in plasma expanding procession, by taking advantage of their different spatial and temporal evolution characteristics.

Experimental setup

The experimental scheme used for this work is similar to that described in previous studies [7-10]. Briefly, a laser beam from a Nd:YAG laser (Quanta Ray, Spectra Physics) was focused through a quartz lens (111 mm focal length) on a pure (99.99%) zinc metal target located inside a vacuum chamber (10-6 Torr) to ignite a plasma. The laser beam was operated in fundamental IR (1064 nm) modes with 5 Hz repetition rate and the pulse width of 10 ns. The spatial visible image of expanding plasma produced by four different laser intensities were given in Fig.1, which were recorded by digital camera. A spectrometer equipped with 1200/mm grating (blazed at 500 nm) was employed to disperse the plasma emission, and covering the spectral range of 180-850 nm at

0.05nm wavelength resolution. The emission spectra lines from the expanding plasma was detected by a time-gated intensified charge-coupled device (ICCD) (DH740-18F-03, Andor Technology) at different time delays with respect to the ablating laser pulse. A four channel digital delay generator (DG535, Stanford Research Systems) was employed to delay the time gate of the ICCD (t=10ns) with respect to the laser pulse. An optical signal from the scattered pump light was used as a master trigger for the delay generator. The zinc metal sample was mounted on a three-dimensional sample stage, which was rotated to keep a fresh surface for each laser beam.

Results and discussion

Before discussing the characterizations of the plasma emission spectroscopy of Zn atoms and ions, the evolutions of plasma parameters, electronic temperature (T_e) and density(N_e), should be analyzed to find out hot and dense region in plasma expanding. Therefore, the representative spectral lines of Zn atoms and ions can been easily and clearly observed at this suitable location.

The approximate excitation temperature was determined by the well-known Boltzmann plot method [8-10, 12, 13] under the assumption of local thermodynamic equilibrium (LTE).

$$\ln(I\lambda/Ag_m)=-E_m/kT_e+B. \quad (1)$$

Where I, λ and A refer to the relative integrated intensity, the wavelength and the spontaneous emission rate, respectively, g_m is the statistical weight factor for the excited state, E_m is the energy of the excited state, k is the Boltzmann constant, and B is a constant parameter for all ion lines considered. In present work, five spectral lines of Zn atoms at 330.26nm, 334.50nm, 472.21nm, 481.05nm, and 636.2nm were selected to evaluate the electron temperature. The spectroscopic constants of these spectral lines can be obtained from Ref. [11].

A representative Boltzmann plot for the determination of electron temperature at a distance of 5mm from the target surface for the case of the laser pulse intensity ~ 1.87GW/cm^2 was shown in Fig.2. The slope of the linear fit is inversely proportional to the electron excitation temperature. The data were fitted by a least-squares approximation with a result electron temperature of 0.45eV.

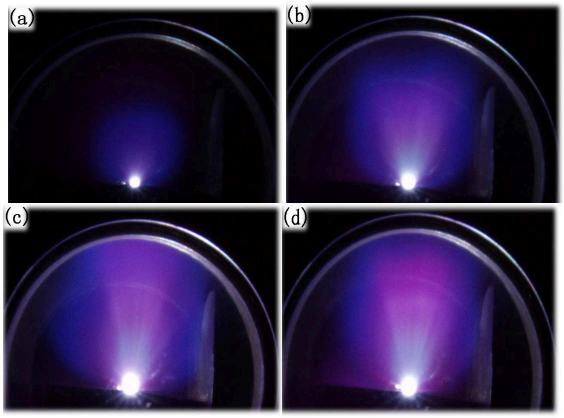

Fig.1 The representative emission images of expanding plasma produced by laser ablating pure zinc metal target, captured by a digital camera.(size of every one is 5cm ×5cm) (laser intensities were fixed at 0.63, 1.21, 1.87, 2.45GW/cm^2).

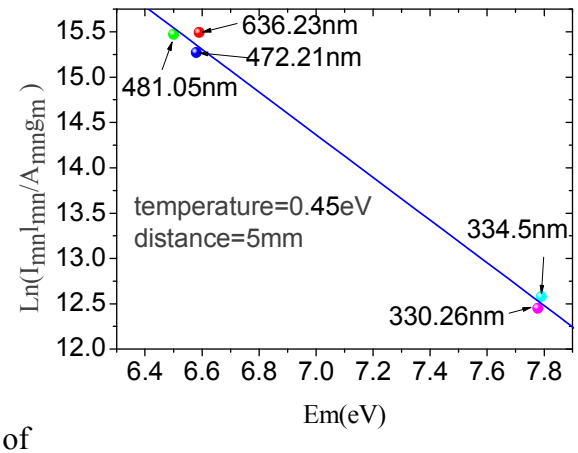

Fig.2 Boltzmann plot for determining the electronic temperatures. Laser irradiation used 1.87 GW/cm^2.

Additionally, the full width at half maximum ($\Delta\lambda_{1/2}$) of Stark broadened profile from well-isolated spectral lines is related with the electron density N_e in plasma through the following relation [8-10, 12, 13],

$$N_e=(\Delta\lambda_{1/2}/2W)\times10^{16}\text{cm}^{-3}, \quad (2)$$

where W is an electron impact parameter, which is weakly related to different temperature. For the evaluation of N_e, in the present work, the Stark broadened FWHM of Zn ions at 334.50 nm was used to determine the electron density. We have used W=0.0327 nm with the increase of temperature in a range of 40000~80000K [22].

Figure 3(a) and (b) illustrate the spatial dependence of electron temperature and density of plasma by four laser intensities ablating on Zn target. As shown, the curves of electron temperature and density versus distance from target surface show very similar behavior. For example, at laser intensity of 1.87 GW/cm^2, N_e first linearly increases from 4×10^{17} cm^{-3} at 0.25mm to a maximum of 5.12×10^{17} cm^{-3} at 0.75mm, and then drops to 1.3×10^{17} cm^{-3} at 3mm, subsequently remains practically constant for longer distance. The spatial profiles of electron temperature and density clearly indicate that the maximal value of T_e and N_e (the peak temperature and density) locates at the 0.75mm from Zn target surface, although the values depend on the laser intensities. As following discussion about the spatial profile of Zn atoms and ions spectral lines, the detection region should be located around 0.75mm from target surface, where plasma temperature and density are higher than other place.

Compared to the spatial profile of T_e and N_e as a function of the distance, in Fig.3(c) and (d), similar analyses were also performed for the temporal evolution of the electron temperature and density at 0.75mm distance from the target surface. We measured the spectral lines with a constant gate width (t=10 ns) but different delay times (50~850 ns) with respect to the laser pulse. In the early stage, it is noteworthy that electron temperature and density first increase up to maximum values at delay time around 250 ns and then decrease at the later stage of plasma expansion. From the results given above, combined with the spatial profiles of peak temperature and density at 0.75mm from target surface in experimental studies, the plasma is also characterized by temporal profiles of peak temperature and density at delay time of 250 ns in the earlier stage of expansion process. Owing to stronger plasma shielding and absorption at high laser intensity, more absorbed energy from laser irradiance can be released quickly in the early-stage evolution of the plasma, therefore the hot and dense particle cloud become more reactive in the earlier evolution of the plasma [6-9]. The conclusions are in agree with that of recent studies on laser ablation of SiC and KTP targets [8, 9], although the values of space and temporal regions are slightly different from our present work.

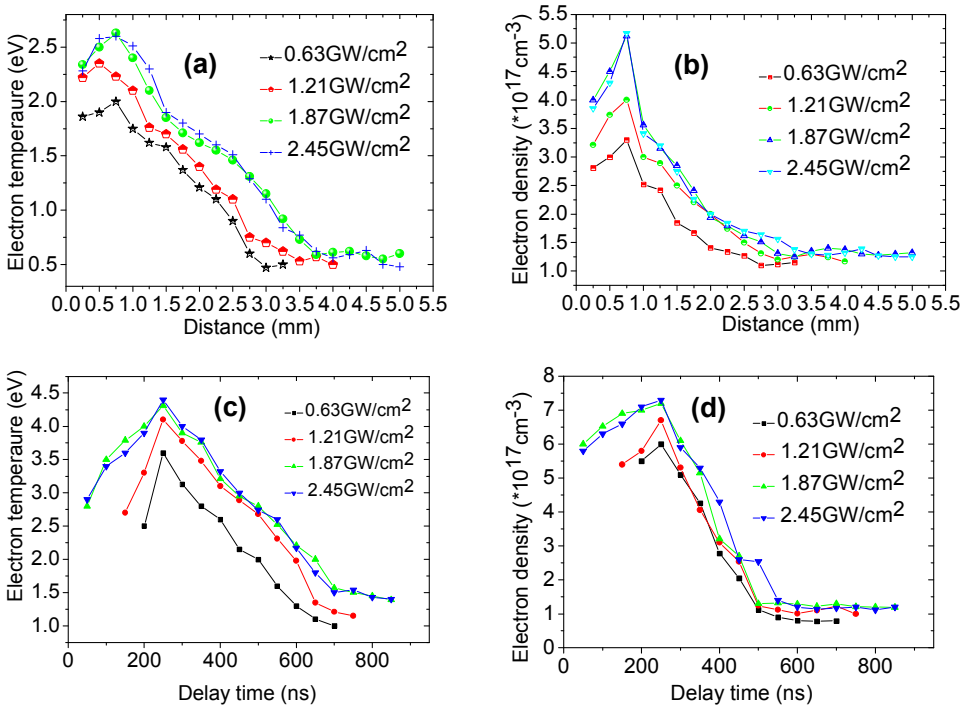

Fig. 3 (a) and (b) show electron temperature and density as function distance from the target surface at four different laser intensities. The temporal evolutions of electron temperature and density of the expanding plasma were displayed in (c) and (d).

Figure 4 shows four well-isolated spectral images (upper panel) and lines (lower panel), emitted from Zn atoms (at 468.01nm, 472.21nm, 481.5nm) and single-charged Zn ion (at 491.16nm), respectively, which were detected at 0.75 mm from target surface by using time integrated CCD chip. The incident power was fixed at 2.45 GW/cm^2. It should be pointed out that the spectral lines of other Zn atoms, such as 307.5nm, 692.83nm, 693.84nm, 694.3nm were also observed at our experiment. While, some of these spectral lines are likely interfered by each other, and the average intensities of these spectral lines are much lower than that selected in Fig.4. Moreover, the emission lines from multi-charged Zn ions (except for single-charged at 491.16nm in Fig.4) can not clearly detected by present detection system (180-850nm) any more. As seen from Fig.4, the intensities of Zn atoms spectral lines are much higher (almost a factor of 4 to 12 times) than that Zn ions at 491.16nm, which confirms that the number of Zn atoms in plasma by laser ablated zinc metal is much larger than Zn ions.

To provide crucial information for improving the analytical capability of PLAPES, the temporal evolution of the Zn ions in the plasma expanding should be taken in to consider. Figure 5 shows the emission spectral lines of Zn atoms and ions at different delay time (gate width of 10 ns) with respect to the laser pulse, measured at 0.75 mm from the target surface. It is interesting to see that the lifetime scale (~300ns) of the line at 491.16 nm from Zn ions is much shorter than that (longer than 800 ns) for Zn atoms spectral lines. However, at the early stage evolution(less than 150ns), compared to Zn atoms, higher intensities spectral line for Zn ions at 491.16 nm ((up to three times than Zn atoms spectral lines) were presented. Considering that the most absorbed energy from laser irradiance was released at delay time 250 ns in our experiment, dense Zn ions should be formed directly by the laser- zinc metal interaction, and Zn atoms are partly produced by this process. The absorbed laser energy by plasma shielding can not provide more Zn ions at late-stage plasma expansion, because higher energy must be required for ionization (transition from atoms to ions), while a lot of Zn atoms are present at this time region by electron-ion inverse bremsstrahlung process and the collision within neutral. The understanding of the characteristics of Zn ions in the plasma expanding by laser ablating pure zinc metal will be very important for remote material analysis by plasma emission spectroscopy.

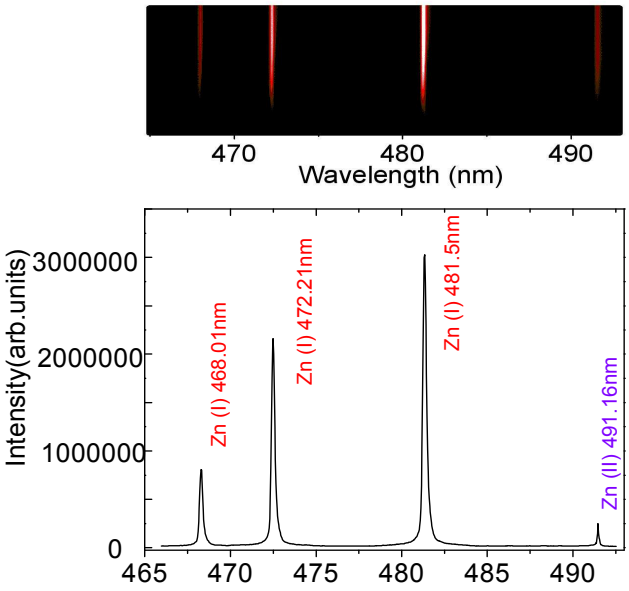

Fig. 4 The spatial evolutions of the representative well-isolated spectral images (up panel) and lines (down graph) taken from Zn atoms and ions in the expanding plasma produced by 2.45 GW/cm^2 laser irradiations.

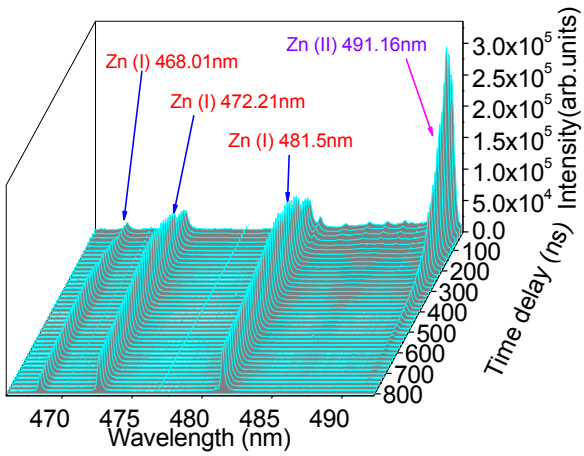

Fig. 5 The early-stage evolution of the emission spectra lines from Zn atoms and ions versus delay time (gate width of 10 ns) with respect to the laser pulse, measured at 0.75 mm from the target surface.

Conclusion

In summary, detailed analyses of the spatial and temporal dependence of Zn ions spectral line in plasma produced by ablation of pure zinc metal were reported. The plasma with the spatial profiles of peak temperature and density at 0.75mm from target surface and temporal profiles of peak Te and Ne at delay time of 250 ns with respect to laser pulse have been discussed. Compared to Zn atoms, our results revealed that Zn ions in the plasma are characterized by weaker intensity in spatial resolved profiles and shorter decay times in temporal evolution, but higher bright in early-state plasma expansion.

Keywords: Circulating fluidized bed. bed pressure. lignite combustion. SO2; NO; combustion adjustment.

Abstract: For study on SO2 and NO emission characteristics of circulating fluidized bed boiler experiments were carried out in a 300MW circulating fluidized bed boiler. In these experiments, the variables were the amount of limestone and bed temperature. While conducting the test, the reasons for the changes in emission were analyzed, and some advices about combustion adjustment were proposed.

Introduction

GB13223-2011 implemented from January 1, 2012, the emission concentration of SO_2 and NO circulating fluidized bed boiler this standard has more stringent requirements, the provisions of its emissions should not exceed 200mg/m^3. In the circulating fluidized bed boiler in actual operation, some factors that influence on SO_2 and NO emission is different, even contradictory[1]. Therefore, how to control these two kinds of emissions is an unavoidable problem in the process of the development of circulating fluidized bed combustion technology. This paper studied the problem, and put forward some optimization measures.

Research Process

Object Of Study And Research Process

The test of boiler is circulating fluidized bed No. 1 boiler from Yunnan. This is the use of technology for the design and manufacturing of ALSTOM company. Boiler is a subcritical pressure, natural circulation, single cylinder, the balance of circulating fluidized bed boiler ventilation, fueled with lignite. Boiler with maximum continuous load (BMCR condition) as design parameters, maximum continuous evaporation capacity of the boiler is 1025t/h. Unit load is 300MW and rated capacity is 934.8t/h.

In the design of combustion of coal and checked coal, limestone into the design of Ca/S molar ratio of 2, the dry flue gas oxygen content is 6%, SO_2 emission concentration is less than 400 mg/Nm^3.

Study on the test method of the industry, the test process as follows:

(a) In tail flue outlet with Fourier transform infrared gas analyzer and electrochemical oxygen analyzer for direct measurement of NO concentration in flue gas, SO_2 and O_2 concentration.

(b) CFB boiler test is divided into three parts. The first part is to make the bed temperature were stable at 785℃,800℃,805℃ and 815℃, keeping other relevant data such as the amount of limestone, bed pressure, load, oxygen and other conditions do not change, the acquisition of N_2O and SO_2 emission concentration.

Coal and Sorbent Of The Test

Blended coal used in the experiment is Buzhaoba coal and Xinshao coal blended in a 1:1 ratio blended coal. Table 1 shows the coal of the test.

Table 1 Test coal Overview

Test items	Test results
M_t(%)	44.68
A_{ar}(%)	12.22
V_{ar}(%)	24.87
FC_{ar}(%)	18.23
C_{ar}(%)	24.75
H_{ar}(%)	2.11
N_{ar}(%)	0.48

Limestone were used in each experiment from the same origin, were maintained in diameter 3mm, Table 2 is an overview of test limestone.

Table 2 Limestone profile test

SiO_2	1.0%
Al_2O_3	0.14%
Fe_2O_3	0.18%
CaO	55.11%
MgO	0.56%
SO_3	<0.15%
Mt	0.23%
LOI	41.32%

Research Results And Analysis

Effects of the bed temperature on the concentrations of SO2 and NO emissions

The test load is 300MW, limestone amount of 100t/h, oxygen control at 2.0%, the bed pressure stabilized at 6.3KPa. The results show in the Figure 1.

Effects of bed temperature on SO_2 emissions concentrations

Figure 1 shows that, with the gradual rise in bed temperature between 770℃~ 815℃, the concentration of SO_2 emissions also increase. This conclusion results contrast with many studies .This is because the test plant at high altitude, air pressure and density are relatively low, resulting in reduced fuel combustion reaction speed, air and flue gas volume expansion, and limited the furnace space, making the flue gas residence time in the furnace becomes shorter, burning incomplete. In the test conditions, to maintain a certain amount of coal, relatively low combustion temperature, combustion of lignite was not yet fully brought out the furnace flue, although circulating fluidized bed combustion boiler materials will cycle, but still inevitably causing sulfur incomplete combustion, making the low flue gas SO content. As the combustion temperature gradually increased, more and more fuel combustion, emissions of SO_2 concentrations increased accordingly.

Table 3 shows the test results of slag samples under different bed temperature:

Table 3 Slag sample test results

Bed temperature(^oC)	785	800	805	815
Fly ash slag combustibles(%)	1.50	1.28	1.11	0.93

It can be found, as the bed temperature rises, fuel ash content decreased. It shows the extent of coal getting high.

Effects of bed temperature on the concentration of NO emissions

With the bed temperature high, NO emission concentrations continue to rise. When fuel combustion, there are two main ways the conversion of fuel N. One is to generate NO, the other is generated N_2O. Particular reaction process is as follows:

$$HCN + O \rightarrow NCO + H \quad (1)$$

$$HCN + OH \rightarrow HNCO + H \quad (2)$$

$$HNCO + OH \rightarrow NCO + H_2O \quad (3)$$

$$NCO + NO \rightarrow N_2O + CO \quad (4)$$

$$NCO + NO \rightarrow N_2 + CO_2 \quad (5)$$

$$NCO + O \rightarrow NO + CO \quad (6)$$

$$NCO + OH \rightarrow NO + CO + H \quad (7)$$

As the bed temperature increased, the degree of coal volatiles also continues to deepen, the amount of HCN and NH_3 are also increasing. Studies show that when the bed temperature is less than 600℃, the HCN oxidation reaction is carried slowly. With the temperature increase, the reaction get much faster. As can be seen from the above reaction, HCN can either generate NO, also can generate N_2O. Since both N sources are volatile N, so the ratio of NO and N_2O is the shift in the relationship. When the bed temperature is gradually increasing, the reaction (4) is suppressed, the reaction (6) is strengthened, so in this case the concentration of NO emissions continue to rise with the bed temperature.

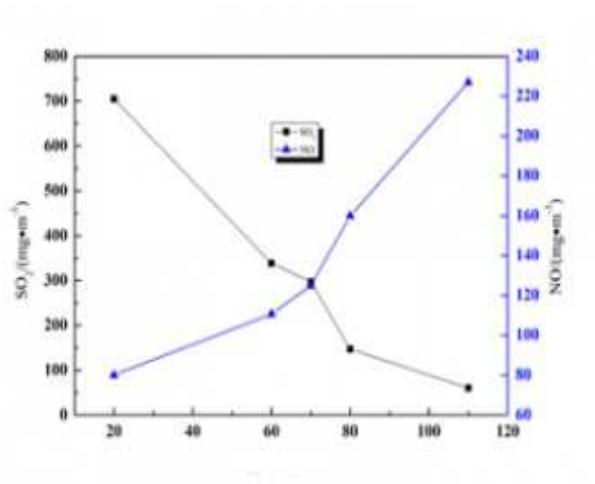

Figure 1 Effects of bed temperature on the concentrations of SO_2 and NO emissions

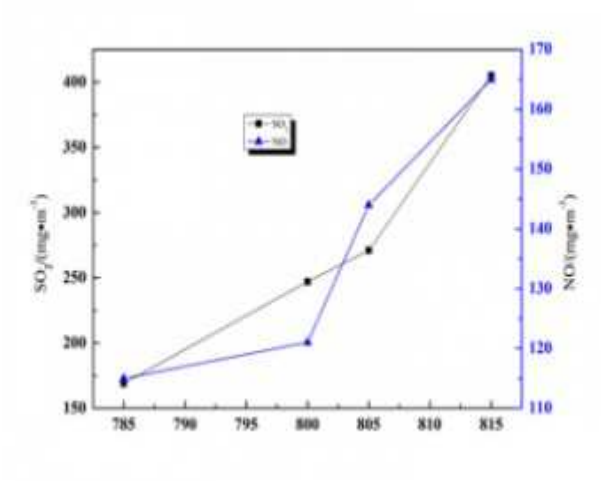

Figure 2 Changes affect the amount of limestone on NO and SO_2emissions

Impact of changes in the amount of limestone

The test load is 300MW, bed temperature control 835℃, oxygen stable at 2.3%. The test result shown in Figure 2.

Affect the amount of limestone concentration of SO_2 emissions

As can be seen from Figure 2, the amount of coal remain unchanged, increase the amount of limestone, the concentration of SO_2 emissions show a downward trend. Increasing the amount of limestone calcium sulfur ratio becomes large, which makes the desulfurizing agent to capture more SO_2, thereby increasing desulfurization efficiency. But it is worth noting that with the increase in the amount of limestone desulfurization efficiency of growth will gradually slow down. In Figure 2, when the amount of limestone increased from 20t/h to 80t/h, the SO_2 emissions decreased 700 $mg \cdot m^{-3}$ to 100 $mg \cdot m^{-3}$, the rate of decrease approaching 10mg/t, but when the amount of limestone from the 80t/h increased to 110t / h, SO_2 fell only about 50mg, decreased rate of 1.8mg/ t. Decline in SO_2 slows. Considering the increasing amount of limestone, will increase the operating costs of power plant, so the amount of limestone should not exceed 80t/h.

Affect the amount of limestone concentration of NO emissions

For the emission concentration of NO increased with increasing the amount of limestone, some scholars believe is the impact of desulfurization, $CaSO_4$, on the reaction of NH_3-NO[3]. However, according to recent research, it shows that this argument is not comprehensive. After an increase in the amount of limestone, the furnace has a lot of CaO exist, and CaO fuel nitrogen is converted to NO strong catalyst[4]. Although CaO for CO and H have catalytic reduction of NO, the impact of the latter is less than the former, so the increase in the amount of limestone, NO emissions increased. In addition, there are scholars believe that limestone can also catalyze HCN and NH_3 generate NO, thereby inhibiting the volatile N to N_2O change, while also increasing the amount of NO generation[5].

Combustion Adjustment Programs

When the bed temperature changes, SO_2 and NO emission concentrations were increased. When the bed temperature at 790℃or less, SO_2 emission concentration less than 200 $mg \cdot m^{-3}$ and NO less than 125 $mg \cdot m^{-3}$. Therefore, we can try to make the bed temperature lower, but when the bed temperature too low, it will make the boiler output decline. However, within the scope of the study, the main-steam flow varies only with the bed temperature changes, smaller changes between 947.51t/h to 963.8t/h, therefore when the bed temperature dropped to 785℃ impact on boiler output is not great, bed temperature control can be considered at about 785℃, in order to reduce the concentration of pollutants discharged as possible.

In the test, with the increase in the amount of limestone, and the concentration of SO_2 emission reduction, the concentration of NO emission increase. According to GB13223-2011 thermal power plant air pollutant emission standards, SO_2 emission concentration should be controlled at 200 $mg \cdot m^{-3}$ or less, so the amount of not less than limestone 75t/h. Although limestone continues to increase, SO_2 emissions will significantly reduce the concentration of smaller changes in the concentration of NO emissions, considering the desulfurization economy, limestone amount held in the 80t/h more appropriate.

Laying the Ground of Indoor Restrooms by Using Foam Glass and Waterproof Coating

Shuomang Shi[1, a]

[1]Southwest Jiaotong University, Chengdu, Sichuan, China

[a]ssmabc@sina.cn

Keywords: Basements, restrooms, furring brick, foam glass, pure acrylic coating, silicon sealant

Abstract

This article presents a new design of waterproof ground for rest rooms in basements by using new materials and new combination. First use cement mortar to paste the waterproof and heat resistance foam glass furring bricks which have low density and high strength on the ground. Then use silicon sealant to fill the gap between the bricks. Roll brush the multifunctional transparent elastic waterproof coating pure acrylic JQ - 168 on the bricks as surface. The combination of the two formed a sealed waterproof ground in indoor restrooms with certain strength and toughness. So this kind of ground surface can have stable and reliable waterproof function when in face of the situation that groundwater upwelling through fissures in concrete created by resistless damage like earthquake and so on.

Research background

Nowadays in China, the use of underground space more and more appear in all kinds of civil and public buildings due to the pressure of population and demand for land conservation, such as subway, underground shopping malls, residential basement, etc. So here come many underground restrooms. A restroom itself is in a moist environment. Cause the ground of restrooms directly contact with water. Also it can be infiltrated by moist air or water from the lower concrete because of the rupture from external force. And the basements are usually immersed in wet soil at the area where groundwater level is higher than average. Therefore, the ground of the basement is bound to waterproof and waterproof processing. The main methods are waterproof coating and using waterproof roll in China. [1]But once the water-resisting layer is damaged due to external factors such as earthquakes the function of waterproof is gone. So it demands that indoor waterproofing methods can compensate the water proofing property losses due to the structure failure. At present people use porcelain bricks and Mosaic on the ground on most of the floor. And lay waterproof roll under them. But the function of waterproof will be lost if the layer was damaged with structure failure. Considering this, we are using waterproofness and toughness of foam glass with silicon sealant and transparent waterproof surface coating to make the inner defensive line of a restroom underground.

Materials

Foam glass: Foam glass refers to the evenly mixing material made of various kinds of waste mineral residue by adding an appropriate amount of foaming agent, flux and various kinds of modified additives mixtures. They can be transformed into porous glass after preheating, melting, foaming and cooling technology. Inside the foam glass there are numerous small, uniform, connected or closed pores, so this is a uniform system of gas phase and solid phase. The microstructure is shown in Fig.1. The volume of pore makes up 50%-95% of the total. And the diameter of the pores range from 0.5 - 5mm. Foam glass has low density, large closed porosity,

Low thermal expansion coefficient, low coefficient of thermal conductivity, stable thermal performance, nonflammable, long-life, strong corrosion resistance, and many other advantages. [2]

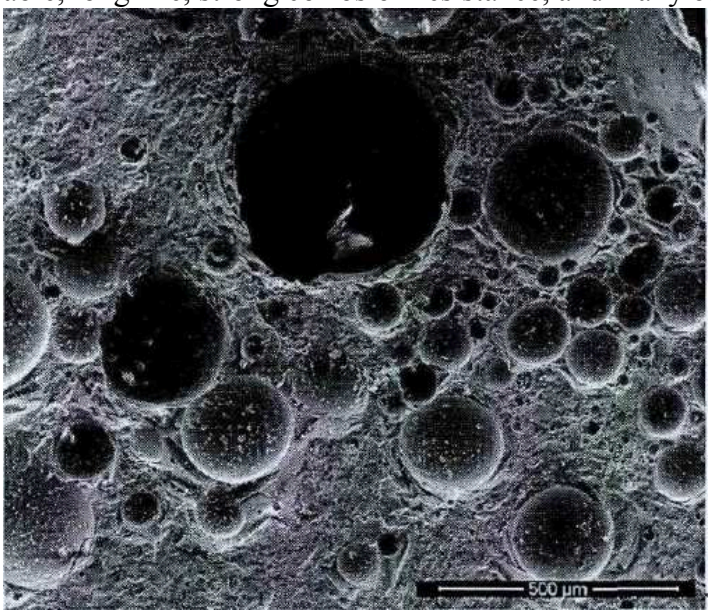

Fig.1. The microstructure of foam glass

The multifunctional transparent elastic waterproof coating JQ - 168: It is made of pure acrylic as the main raw material, mixed with a certain proportion of cationic surfactant, coupling agent. The coating is non-toxic, tasteless, and nonflammable. (Features are shown in Table.1) Its liquid is white uniform paste without aggregation and will become colorless and transparent after condensation. It has excellent waterproofness, tenacity and weather resistance. [3] The microstructure of pure acrylic is shown in Fig.2.

Table.1. Features of pure acrylic

Features of pure acrylic	
Appearance	milky white liquid
Dry time of surface/h	≦4
Time of absolutely dry/h	≦12
Tensile strength/Mpa, 20°	≧300%
Impervious(0.3Mpa, 600min)	None
Cohesiveness/Mpa	≧02-0.3
Heat resistance(852 C,5h)	No flowing air bubbles
Freezing and thawing cycles(10)	normal

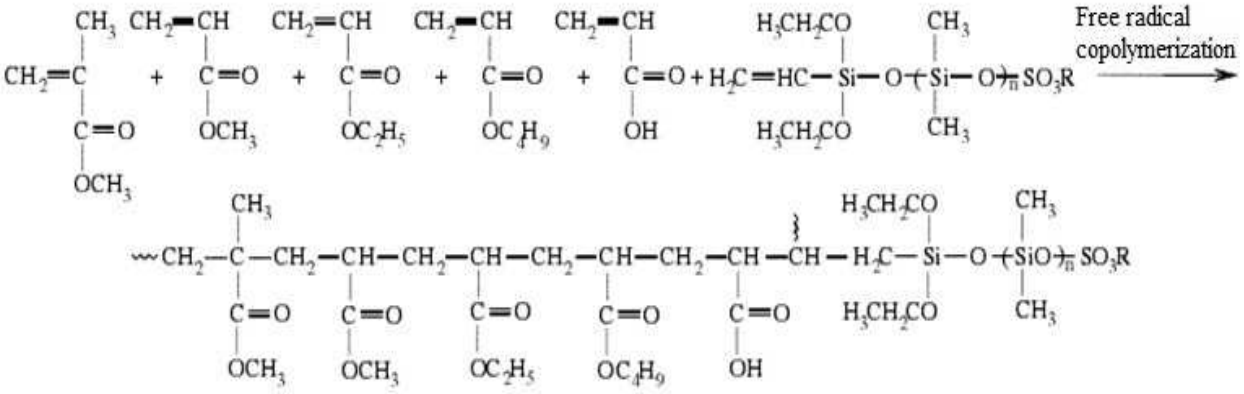

Fig.2. Microstructure of pure acrylic

Construction principle and methods

Structure principle: This scheme takes advantage of the two kinds of waterproof materials synthesis as a whole. Firstly we make foam glass into a certain specifications of the watertight ground brick for the convenience of use and arrangement for the convenience of use and arrangement. We use cement mortar set the bricks on the ground as the main body of the waterproof. Then we use silicon sealant to fill the gaps between the bricks to make the bricks into a whole and let the surface be flat. Secondly we brush a layer with certain thickness of pure acrylic coating on them. [4]So the bricks and the layer form a seal inside which can bear and resist the water in the inner space and prevent the moisture from the concrete outside it. So the inner space can be prevented from water seepage and leaking.

Construction method:

a) Apply cement mortar evenly on the concrete ground. Lay prefabricated foam glass bricks with standard 50cmx50cmx2cm and leave 3-5mm wide gaps between them.

b) Clean up the gap of cement mortar with scraper become to a depth of about 9-10 mm gap.

c) Inject silicon sealant after cement mortar's solidification. Scrape the surface till smooth and flat. Repeat this step 3 times to ensure the Inject silicon full of gaps without air.

d) Brush or spray pure acrylic coating JQ-168 on bricks and silicon sealant with a thickness of 1.2-1.5mm. Brush a second layer after the solidification of the previous level. Repeat this till 3 times to get a thick transparent elastic waterproof layer.(The schematic and design sketch ore shown in Fig.3 and Fig.4)

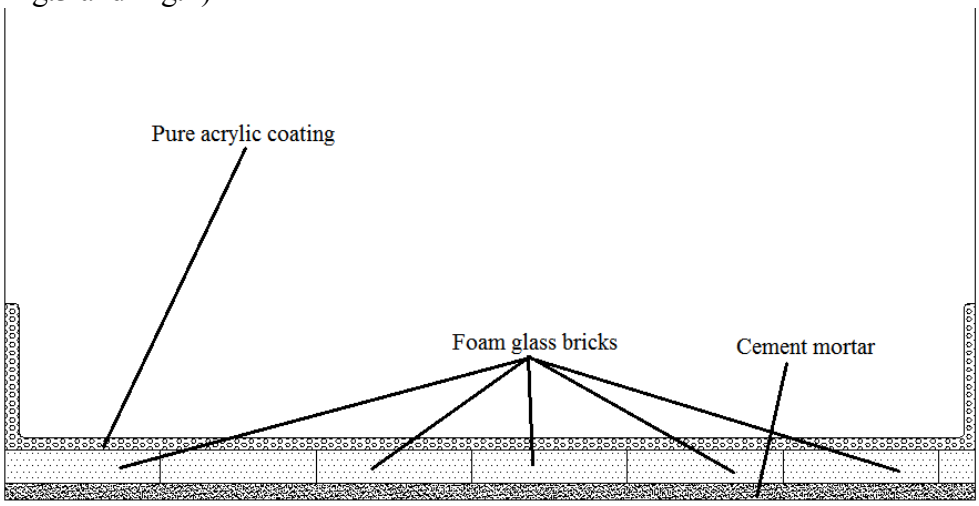

Fig.3. Schematic of the design

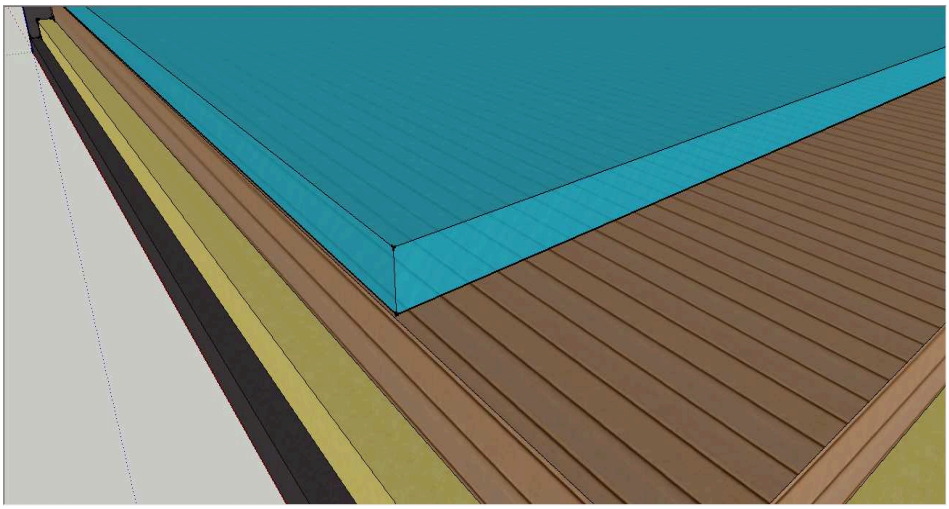

Fig.4. Design sketch

Characteristics and the advantages and disadvantages analysis

Characteristics of materials: The main body foam glass is a kind of inorganic non-metallic material after high temperature foaming. It has properties of fire prevention, waterproof, non-toxic, corrosion resistance, moth-proofing, not aging, no radiation, insulation, anti-magnetic wave, antistatic, high mechanical strength and a good bond to all kinds of cement. Besides the raw material of foam glass is wasted glass and industry residue. These avoid the waste of heat and a large number of manpower and material resources waste in the aspect of production material to let secondary utilization of the waste possible. This can have the effect of energy conservation and emissions reduction, in line with the requirements of global low carbon emissions. On the other hand foam glass itself is colorless or translucent white for porosity reasons. So when the production it can be mixed with pigment to form all kinds of patterns and decoration [5]. With the transparent coating on the top it can achieve the aesthetic of interior decoration and design requirements.

Defect analysis: The construction steps are a little bit complicated. During the process we have to wait for the consolidation of the cement to inject silicon sealant, and the consolidation of the previous waterproof coat to brush the next level. All these will lead a waste of time. What's more it calls for strict demand. During the process a light touch or disturb will cause the surface no longer a flat one and that will cause an excessive loss while using in the future which would lead to a partial failure.

Conclusion

This design uses a new type of combination which uses low-cost environmental protection material foam glass as bricks and multifunctional transparent elastic waterproof coating as surface, offers an effective solution for the demand of waterproof in places where contact water a lot.

In the aspect of function it can satisfy the waterproof and moisture-proof requirements of civil space. In the aspect of exterior it can be beautiful and has the function of decoration. Adding the good carrying capacity, corrosion resistance and durability, it can be the first choice when it comes to a waterproof inner space.

Influence of Mo addition on a nickel-base single crystal superalloy

Kai Zhao [1, a]

[1]School of Metallurgical and Materials Engineering, Chongqing University of Science and Technology, Chongqing, 401331, China

[a] tony_zk@163.com

Keywords: superalloy; Mo; lattice misfit; creep rupture strength

Abstract. The influence of minor Mo addition on the lattice misfit and creep rupture strength of a new single crystal superalloy have been investigated. It was shown that Mo can reduce the lattice misfit; increase the tendency of forming TCP phase; extend the time to material failure.

Introduction

Mo is one of the main refractory strengtheners in nickel-base superalloys. Since high temperature creep was generally diffusion controlled, additions of Mo were quite effective in reducing creep rates because Mo diffused very slowly in nickel. Mo was found to have a similar effect as rhenium in a fourth generation single crystal superalloy—TMS-162, in which the effects of tantalum and niobium additions were not so significant. These were also considered to be attributed to the increase of the magnitude of the lattice misfit, which was believed to be beneficial because of stronger γ/γ′ interfaces [1]. Mo markedly increased the γ′ phase solvus temperature; correspondingly, the weight fraction of γ′ phase increased with Mo additions. Lattice parameters of both the matrix and the γ′ phase were increased markedly by Mo [2]. Mo additions were also very effective in reducing the coefficients of thermal expansion [3].

However, more Mo additions resulted in the degeneration of mechanical properties due to the precipitation of topologically closed packed (TCP) phases. Accordingly, reducing the Mo content by only 0.73 mass% increased the creep rupture life by a factor of three, because the precipitation of TCP phase was eliminated [4].

Mo oxidizes rapidly at elevated temperatures. The complexity of the problem resides in the volatility of Mo trioxide, the end product of the oxidation reaction, which prevents the possible formation of protective oxides. At about 770℃ the rate of evaporation of Mo trioxide equals its rate of formation and, as temperature increases, the volatilization rate becomes extremely rapid [5]. Also, some authors [6-9] suggested that Mo was detrimental to hot corrosion resistance of simple ternary nickel-base superalloys. However, it was reported that Mo significantly reduced the amount of hot corrosion attack at 870℃ for the aluminum-containing alloys. For the titanium-containing alloys tested at 870℃ and all alloys exposed at 980℃, Mo exerted little influence on hot corrosion behavior [10]. Zheng et al. [11] thought that Mo may accelerate acid fluxing action, which may result in the catastrophically accelerating effect. Generally, the Mo content in nickel-base superalloys is less than 2 mass%.

Several research investigations have studied the influence of Mo on the microstructure and creep properties of nickel-base superalloys [12-13]. Most of the previous studies were concerned with the superalloys bearing high Mo contents. In present paper, we will focus on the lattice misfit and creep rupture strength of a new single crystal superalloy with minor Mo addition.

Experimental procedure

Three experimental superalloys have been used in this study. Nominal chemical compositions of these alloys are listed in Table 1.

Table 1 Nominal compositions of the experimental alloys (mass %)

Alloys	Cr	Mo	W	Al	Ta	Ni
1	9	-	8	5.4	10	Bal.
2	9	0.4	8	5.4	10	Bal.
3	9	1.2	8	5.4	10	Bal.

Samples used for experiments were vacuum induction melted and fabricated using standard directional solidification casting procedures; materials were supplied as 10 mm diameter cylindrical bars with orientations within 5° of the [001] orientation. Samples were given the following heat treatments: 1320℃/5h+1100℃/4h +870℃/20h, followed by air cooling.

Specimens were mechanically polished and then electronically etched (2V d.c. and 0.2 A) by 21 ml H_3PO_4+17 ml H_2SO_4+12 ml H_2O. Specimens were observed by using a JEOL-JSM6060 scanning electron microscope (SEM).

Results and discussion

1. On the lattice misfit

Fig. 1 summarized the dependence of the lattice misfit on Mo content in nickel-base superalloys. Mo was found to reduce the lattice misfit, although data were somewhat different in different alloying systems [14-17].

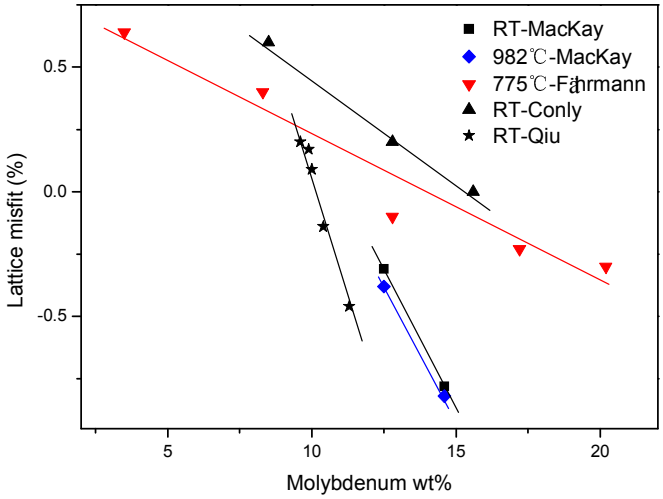

Fig. 1 Lattice misfit as a function of molybdenum contents.

2. On microstructure stability

Mo was the strongest for the tendency of forming TCP phase, rhenium, tungsten, and chromium the second place, and cobalt and niobium the weakest. However, no TCP phase was observed in the alloys bearing 12.5 wt% Mo [16]. In the present three alloys, TCP phases were observed in Alloy 3, which mainly distribute in the dendritic core. Alloy 1 and 2 contained no TCP phase.

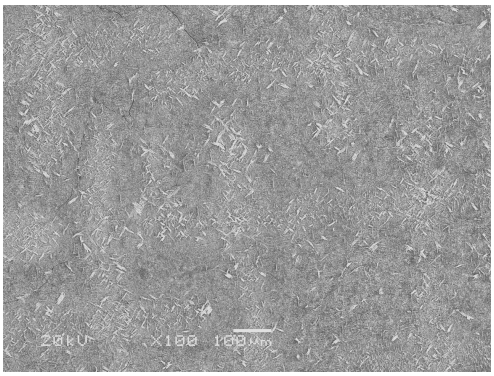

Fig. 2 TCP phases precipitated in Alloy 3 (1100 ℃/600 hours).

3. On stress-rupture properties

Fig. 3 shows the creep rupture strengths of the three experimental alloys. Increasing the Mo content substantially extended the time to material failure, except of 1100 ℃/137 MPa.

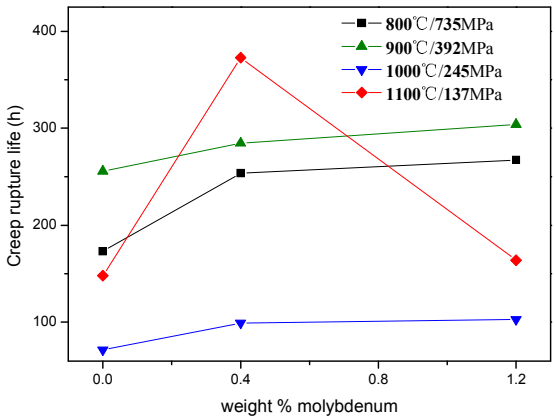

Fig. 3 Creep rupture life as a function of molybdenum contents.

Summary

The influence of minor Mo addition on the lattice misfit and creep rupture strength of a new single crystal superalloy have been investigated. It was shown that Mo reduced the lattice misfit. Mo was the strongest for the tendency of forming TCP phase. Increasing the Mo content substantially extended the time to material failure, except of 1100 ℃/137 MPa.

Keywords: Superhydrophobicity; Wettability; Contace angle; Microstructure

Abstract. Here, a simple method was presented for fabricating superhydrophobic silicon surfaces. Square-pillar-array samples were fabricated on silicon substrates by using the femtosecond laser micromachining technology. We measured the static and dynamic contact angles for water on these surfaces. The contact angles and the rolling angles on the silicon surfaces were measured through an optical contact angle meter. Wettability studies revealed the films exhibited a superhydrophobic behaviour with a higher contact angle and lower rolling angle-a water droplet moved easily on the surface.

Introduction

Wettability is important for solid surface. A surface having water contact angle greater than 150°is commonly called super-hydrophobic. An example of a naturally occurring superhydrophobic surface is the lotus leaf. Upon landing on the surface of a lotus leaf, water beads up to form nearly spherical drops that immediately roll off. Surperhydrophobic materials have attracted much attention due to their potential applications in microfluidic devices where contact with water is detrimental to performance or durability. The decreased contact area between water and solid surfaces in superhydrophobic samples reduces effects such as anticontamination[1], self-cleaning[2,3] and friction of bearing lubrication.

The wettability of a surface depends on both its chemical compositions and surface roughness. Although lowering the surface energy of a substrate decreases its wettability, the water contact angles on smooth hydrophobic surfaces are not exceeding 120°, even when coated with a monolayer of perfectly close-hexagonal-packed-CF3 groups[4]. Inspired by the morphology of the lotus leaf, engineers are trying to mimic nature and produce artificial superhydrophobic surfaces. Some of the numerous approaches employed in the preparations of superhydrophobic surfaces include nanosphere lithography[5], plasma lithography[6], nanoimprint lithography[7], soft lithography technology [8] and multibeaminterference lithography[9], but these mothods are high cost and complicated. Here we have fabricated microstructure surfaces on by a novel femtosecond laser micromachining technology. The wettability of these fabricated superhydrophobic surfaces is studied in detail.

Experimental

Fabrication of silicon-based microstructured surfaces

The substrates with used in experiments were p-type (100) orientated silicon wafers with resistivity of 15-25 Ω.cm. In order to remove chemical impurities and particles, the wafers were cleaned by standard RCA cleaning procedures before micromachining. Fabrication of microstructures was completed by a femtosecond laser micromachining system. The correlative laser parameters are listed as follows: laser wavelength, λ=800 nm; selected laser energy density, U=2.5 J/cm2; and laser scanning velocity, υ=0.4 inch/s. The fabricated microstructures on the surfaces are square-pillar-array structures. The predesigned geometric parameters of the microstructures before fabrication are listed as follows: the upside lengths a of the pillars, the heights h of the pillars, and the spaces b of the pillars.

Characterization

Morphologies of these fabricated superhydrophobic surfaces were examined thermal field scaning electron microscopy (SEM, JEOL，JXA-840, Japan). The WCA were measured by an optical contact angle meter (Dataphysics, OCAH200, Germany) at room temperature after SEM observation. The contact angles for five different positions of the sample were measured and the average was adopted.

Results and discussion

SEM images of the silicon surface with the periodic square-pillar-array microstructure fabricated by femtosecond laser was shown in Fig. 1. It was evidently seen from the observed SEM images that the surface quality of silicon surface with the square-pillar-array structure was very good and distributed periodically on the surface. There weren't almost surface collapse and deformation phenomena on the surface. Uneven surface of the sample with smaller irregular structure, and some reaching the nanometer scale can be seen in Fig. 1. This is due to laser interaction with the silicon surface and the photon avalanche ionization caused by the nonlinear absorption on the material surface, leading to permanent damage and forming a large number of irregular fine structure on the square-pillar-array surface.

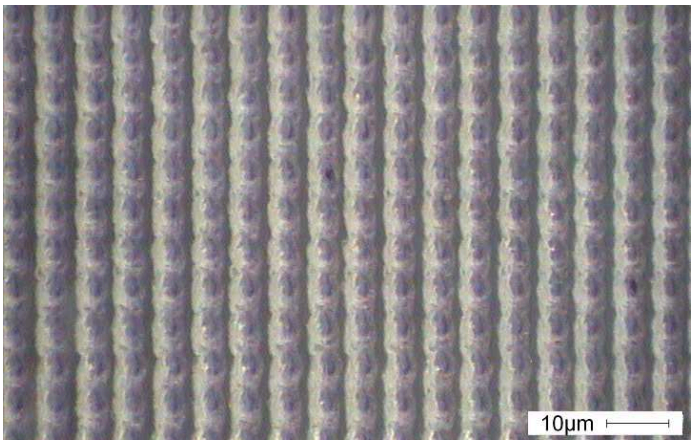

Fig. 1 SEM image of the surface of the square-pillar-array structure

Contact angle measurements

Contact angle measurement is probably the most common method of solid surface tension measurement. One of the most frequently used methods of contact angle assessment is the sessile drop technique. To compare the wettability of smooth silicon surface with that of silicon surface with square-pillar microstructure, the static contact angle of water on both surfaces were measured using the sessile droplet method and the results were shown in Table 1.the results showed that the smooth surface was hydrophobic (CA=99.2°) and the textured surface was superhydrophobic (CA=159.3°). The shape of water droplet on the both surfaces showed in Fig.2. It was clearly seen that the droplet sit on the peak of the roughness (Fig. 2b) and the light could pass through the space in the depressions of the rough surface, which indicated that a composite surface was formed on the textured silicon surface.

Cassie and Baxter[10] studied abundant superhydrophobicity in nature, they put forward a concept of composte contact. It is assumed that the liquid forms composite surface on the rough substrate as shown in Fig.2b, i.e. if microstructured surface is hydrophobic enough, the liquid does not fill the grooves on the rough surface and the droplet is just sitting on the air and protruded surface.

Cassie and Baxter also obtained the equation, which adapts to any composite surface contact from a thermodynamic point of view.

Table 1 Contact angle of surface of the as-fabricated samples (°)

samples	Contact angle θ/°					Average θ/°
	1	2	3	4	5	
Smooth silicon surface	94.9	96.6	104.9	97.5	102.2	99.2
Microstructure surface	159.6	158.2	156.9	160.4	161.5	159.3

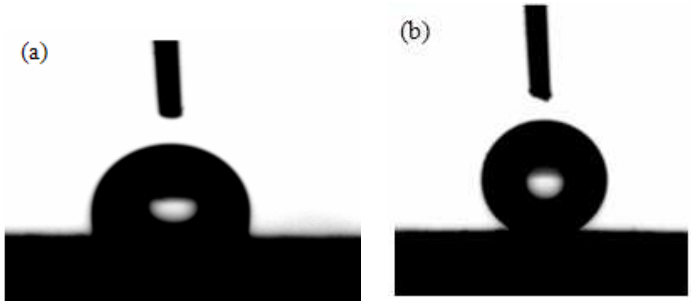

Fig. 3 Photographs of water droplets on the sample surface of (a) the smooth silicon surface, and (b) the square-pillar microstructure silicon surface

$$\cos\theta^* = f_1 \cos\theta_1 + f_2 \cos\theta_2, \quad (1)$$

Where θ^* is the apparent contact angle of the composite surfaces, θ_1 and θ_2 are the intrinsic contact angles of two materials, respectively, and f_1 and f_2 are the fractions of two materials of the compostie surfaces ($f_1 + f_2 = 1$).

When one of these two materials is air, whose contact angle for water is 180°, eq. (1) are can be transform as follows,

$$\cos\theta^* = f_1(\cos\theta_1 + 1) - 1, \quad (2)$$

Equations (1) and (2) are the formulaic expressions of Wenzel's and Cassie's classical wetting theories. In addition, de Genne et al. proposed another wetting mode, i.e., the Cassie impregnating wetting state where crannies of the solid are wetted with liquid and the solid convexities are dry. The Cassie impregnating wetting regime is described with equations that are different from the Wenzel and Cassie heterogeneous ones. In this regime, when the Young's angle is less than a critical value calculated by the equations, the liquid film impregnates the texture; however, remaining islands emerge above the "absorbed" liquid film.

Conclusion

The textured surface with periodic square-pillar-array microstructure been fabricated with different parameters by a novel femtosecond laser. The wettability of such square-pillar-array samples was investigated. The microstructured surface showed superhydrophobic with higher contact angle and lower rolling angle. The results showed that these discrete pillars formed microstructure in the surface, which was strongly affected the contact angle and the rolling angle. On the basis of this sutdy, superhydrophobicity of silicon-based microstructured surfaces using femtosecond laser may have strong potential applications in the future.

Research on Erosion Resistance of TiB_2 Ceramic Particle Reinforced MMC Coating

Fang Jianjun[1, a], Song Yunjing[1] and Li Zhuoxin[2]

([1.] New Energy Training Department of State Grid Technical Institute, No. 500, South Erhuan Road, Jinan City, Shandong Province, 250002;

[2.] Material School of Beijing University of Technology, No. 100, Pingleyuan, Chaoyang District, Beijing City, 100025)

Keywords: TiB_2, metal matrix composite (MMC), erosion resistance

Abstract. The research uses electric arc spraying with low cost and convenient operation to prepare four TiB_2 particle reinforced composite coatings with high bonding strength and uniform tissue. It makes comparative study on elevated temperature erosion actions of coating and 45CT of electric arc spraying. The results indicate the coating has excellent erosion wearing resistance. TiB_2 particles in M-TiB_2 coating have small size, have good unity with metallic matrix, and are distributed on metallic matrix with high hardness relatively uniformly, and porosity of coating is low. The coating has excellent erosion resistance.

1 Foreword

Erosion wear is material loss phenomenon caused by small particles of liquid or solid impacting material surface by certain speed or angle, and measurement system of erosive quantity has different theoretical models depending on plastic or crisp material; factors that influence erosion wear mainly include various aspects such as particle property, environmental factor and material property. By comparing with welding and other surface technologies, electric arc spraying has various advantages high efficiency, low cost, simple operation, low toxicity of generated gas and especially suitable for site operation with narrow space[1].

Previous research has proven that erosion resistance of metallic matrix ceramic composite coating is better than that of metallic coatings such as self fluxing alloy [2-3]. One of important background of the subject to study metal matrix composite coating that contains TiB_2 is to solve pipe erosion problem of coal fired boiler, so the chapter makes erosion resistance test on developed MCW series four coatings (304L-TiB_2, 304L-TiB_2/Al_2O_3, NiCr-TiB_2/Al_2O_3 and NiCr-TiB_2) with good comprehensive properties, compares them with 45CT coating, and studies erosion resisting mechanism of coating.

2 Experiment process

Elevated temperature erosion wearing test is made on GW/CS-MS device researched by Army Equipment Repair Surface Engineering Research Center by referring to ASTM G76-95 standard. Fuel gas fly ash abrasive grain erosion, and its working schematic diagram is shown in Fig. 1. Test conditions are shown in Table 1.

arc spraying erosion sample to researched four cored wires on 20G matrix. Use JZY-250 type electric arc spraying equipment to prepare coating. Select 20 steel as matrix. electric arc spraying technological parameters: Electric arc voltage is 28-32V, working current is 150-200A, compressed air pressure is 0.5-0.65 MPa, and distance is 100-200 mm. Aluminizing agent formula [4] is (15% Al powder + 85% Al_2O_3 + 0.5% NH_4Cl + 0.5% KHF_2), aluminizing technology is 900℃×2h, and aluminizing layer thickness is about 100 μm. Morphology of fly ash grain is shown in Fig.2.

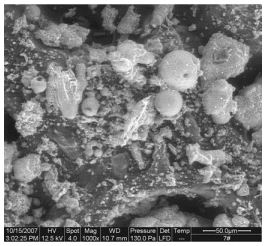

Fig.2 Morphology of fly ash

3 Results and analyze

Erosion test results of TiB_2 ceramic particle reinforced metal matrix composite coating and commercial coating 45CT prepared by electric arc spraying are shown in following Fig. 3.

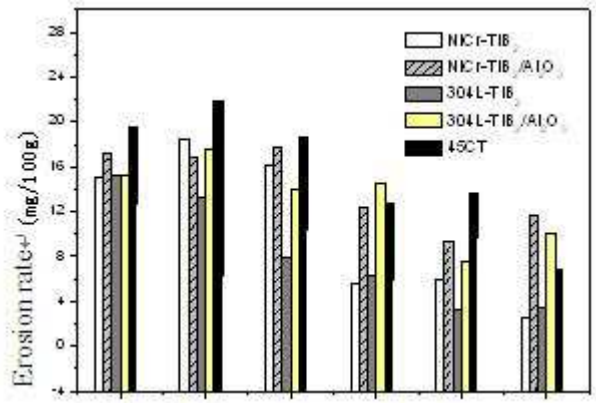

Fig.3 Erosion loss of coatings

It can be seen from the figure that, erosion resistance of TiB_2 ceramic particle reinforced metal matrix composite coating prepared by electric arc spraying is better than 45CT coating in general. According to erosion rate, with change of attack angle, block material is divided into two types, i.e., erosion damage of plastic material and crisp material (Fig. 4).

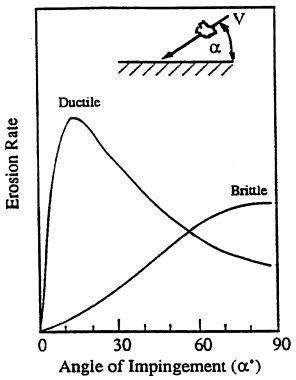

Fig. 4 Relation between erosion rate and erosion angle of both ductile and brittle materials under ideal status

4.1 Influence of erosion angle and temperature on NiCr-TiB_2 composite coating erosion property

Fig. 5 shows erosion test results of coating under different conditions, and Fig. 6 shows coating surface before erosion.It can be seen from Fig. 5, erosion loss of NiCr-TiB_2 composite coating under room temperature and both 30° and 90° is more than that under elevated temperature. Coating under room temperature erosion shows crisp feature (Fig. 7), and surface under 30° erosion shows large quantity of slight crisp cracks. Many plastic rolled protruding crescent lips occur along erosion direction of fly ash particle, after erosion continues, such rolled crescent lips will have crisp collapse. Main damage mechanism of coating is chipping and soyabean residue shaped crisp collapse. Surface of NiCr-TiB_2 composite coating under room temperature and 90°erosion is full of erosion pits, and these damages don't have direction under 30° erosion. Serious loss under 90° erosion is mainly caused by knocking peeling of large flat particle (Fig. 8). According to Suh's [5] delamination wearing theory, under continuous impact load function of abrasive grain, erosion wear process of material can be regarded as generation, growth, expansion, breakage of material sub-surface slight crack, which form stripe abrasive dust and removes from the matrix.

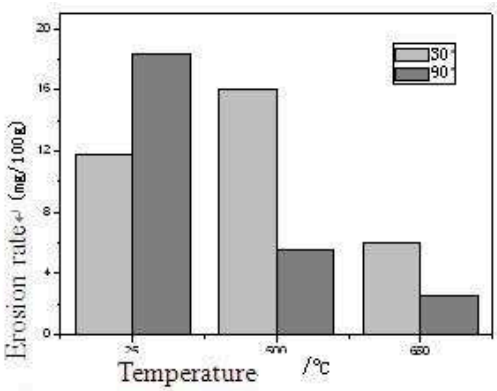

Fig. 5 Erosion results of NiCr-TiB_2 coating under different attack angles and temperatures

Fig.6 Surface of composite coating after mechanic grinding without erosion

Fig.7 Erosion surface of NiCr-TiB_2 composite coating under 30° incidence at room temperature

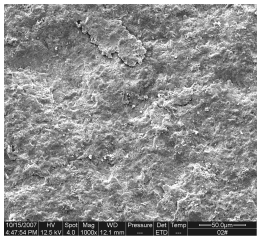

Fig.8 Erosion surface of NiCr-TiB_2 composite coating under 90° incidence at room temperature

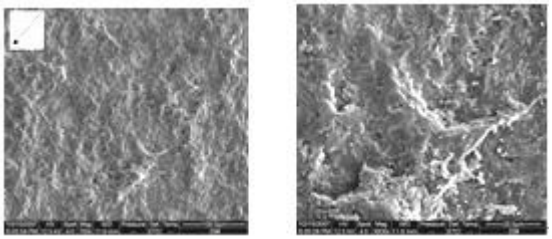
Influence of temperature. Fig. 9 is surface morphology ofNiCr-TiB_2 composite coating under 500℃ and 30° erosion.



(a) Erosion surface (b) Magnification of Fig. a

Fig.9 Erosion surface of NiCr-TiB_2 composite coating under 500℃ and 30° incidence

Fig. 10 shows surface morphology of NiCr-TiB_2 composite coating under 500℃ and 90° erosion. Under room temperature and 90° erosion, NiCr-TiB_2 composite coating shows feature of crisp collapse of large material, after 500℃ and 90° erosion, indentation of surface is small, and is relatively shallow.

It can be seen from Fig. 11, surface of NiCr-TiB_2 composite coating after 650℃ erosion has very small damage and less material loss. Bitter, etc [6, 7] have two explanation on this. One party considers under elevated temperature material surface forms oxide film, and formation of oxide film improves erosion wear resistance of material; another party considers, with increase of temperature, plasticity of material increases, and wearing resistance adds.

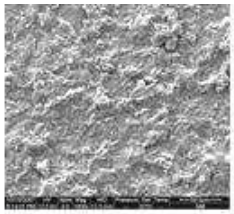


Fig. 10 Surface morphology of NiCr-TiB_2 composite coating under 500℃ and 90° erosion

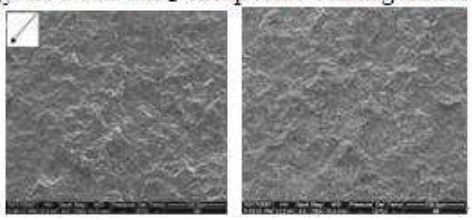
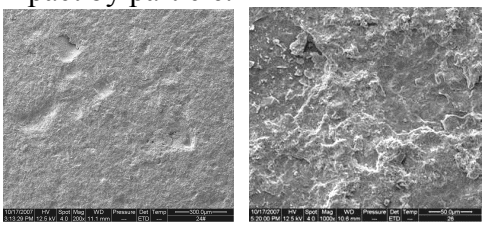


(a) 30° erosion (b) 90° erosion

Fig.11 Surface Morphology of NiCr-TiB_2 composite coating surface under 650℃ and different-angle erosion

Erosion property of 45CT coating

45CT coating is commercial coating material that is widely used in antisepsis and erosion of coal powder boiler pipe, and its erosion rate in test of the research is the highest. Fig. 12 is erosion surface of 45CT coating. Furrow, crack and chipping pit of coating surface caused by erosion particle can be observed under small amplification factor, and this indicates coating material loss is serious. 45CT coating is crisp, surface under 90° erosion finds large quantity of crisp exfoliating, and erosion surface has serious impact by particle.



(a) Under room temperature 30° erosion (b) Under 500℃ and 90° erosion

Fig. 12 Erosion Damage surface of 45CT coating

4 Conclusions

Erosion resistance of electric arc spraying TiB_2 particle reinforced composite coating is better than that of 45CT coating, under various erosion conditions, erosion resistance of NiCr-TiB_2 coating is the best. Under elevated temperature, tenacity of coating increases, and whether combination firmness of ceramic phase and metal adhesion phase is main cause that influences improvement of its elevated temperature erosion wear resistance.Coating with same metal adhesion phase matrix, hardness and porosity of coating, distribution of TiB_2 matrix ceramic phase and combination property with metal adhesion phase decide erosion property of MMC coating.

Keywords: Industrial design, Gray theory, New material

Abstract. Material is the carrier of all industrial design, which is inseparable with. Material is the material basis for human survival and development and new materials is a foundation for future world. With the development of science and technology and rapidly changing times, people have developed more new material on the basis of traditional materials. Based on gray theory of new materials evaluation system, the paper made an analysis and research on a representative of the new materials.

Introduction

Industrial design is a integrated product of technology, art and economic with the development of high civilization. International Council of societies of industrial design made a definition to industrial design that under "the mass produced products", with training, technology, knowledge, experience, and visual feeling of the materials, structures, patterns, color, surface processing, as well as decorated with new quality and qualifications, above all are called industrial design. Industrial design can be divided into two areas of generalized and narrow. Generalized industrial design includes industrial product design, visual communication design and environmental art design, and so on. Narrow meaning industrial design refers to industrial product design as the main research content of the system design[1].

New Materials and Modeling Design of Product

The relationship between new materials and product design is mutual stimulation and promote each other. The emergence of new materials provides a wide design possibility for product design and product design technology is boosting the material development [2].

In the trend of further electronic product, integration, miniaturization, the use of new materials has the potential possibility to break through the traditional structures, and might even lead to a revolution of materials and technology, and to generate a new product designs style. Different materials have different styling potential possibility, as well as visual, tactile feeling contrast with, imagination and reality, fusion of hard and soft, the creative combination of materials and processes, greatly expanding the expressive power of traditional materials.

Adapted to the function at the same time, new material should have also good tactile textures and better interoperability. Through the use of new materials, the design should be given the product a new maximum glamour [3]. For designers, they should be concerned about modeling design of product at the same time, research on physical, chemical characteristics and properties of the materials, in order to better achieve the product functional and emotional function.

The Classification New Material

Material can be classified from the structure, composition, function and application fields, such as a variety of classified angle. The article made a main study to structural materials and functional materials.

New Modeling Structure Material. New modeling structure material, have many kinds, such as a new type of metal materials, new high polymer material, new type of composite materials, a new type of glass material and so on. Some new materials were introduced here.

New Metal Material. At room temperature, the strength of metal plastic is similar to the ultra-high-strength of aluminum-magnesium alloy. Metal plastic have performance of surplus plastic in boiling water, and low temperature ductility and good wear resistance, and corrosion resistance. With a lower than boiling water temperature of the glass transition temperature, metal material can be formed, such as tensile, compression, bending, deformations in the water of around 100 degrees centigrade. It looks like a regular cast iron, which luster is dim. It has hardness, wear resistance, high density at room temperature. Metal material has long service life, and easy to recycle, and environment-friendly.

New Glass Material. For example, nanometer diamond glass, is a kind of new glass material which surface is a layer made up of carbon. The material is hard, crystal clear like a mirror and very metallic.

New-type Ceramic Material. Foamed ceramic material is a shape resembling a porous foam ceramics. This high-tech ceramic has a three dimensional-connected duct, while the shape, whole size, permeability, surface area and chemical properties can be suitably adjusted. As a new type of inorganic non-metallic filter materials, ceramic foam have many advantages such as light weight, high strength, high temperature resistance, corrosion resistance and simple regeneration , long service life and good filtration and adsorption properties and so on. It has properties of simple operation, energy savings, low cost, and filter effects. Ceramic foam can be widely used in metallurgy, chemical industry, light industry, food, environmental protection, energy conservation and other areas [4].

New Type Function Material. New type functional materials is a kind of high and new type material that has special function of electric, magnetic, optical, thermal, acoustic, mechanical, chemical, and biological properties and transformation functions, perception of information and energy. It can be achieved, measurement, display, control, and transformation of non-structural material. In addition to information, energy, nanotechnology, biomedical materials, new type function material include high-temperature superconductivity material, magnetic materials, diamond films, and so on. Typical materials have self-healing functionality, high performance nanometer rare earth permanent magnet materials, memory glass, and so on.

Example analysis

Nanometer diamond glass material has physical performance of hard texture, wear resistant, anti-scratch, anti-contamination, light weight, fire resistant, lower expansion and contraction rates. Nanometer diamond glass material has chemical performance of resistant to mild acids, weak base, oxidation.

According to the various properties of the new materials and their application in products, it can be predicted that the material will be suitable for the outer surface of household appliances, such as refrigerators, freezers, microwave ovens. Application of evaluation method of gray theory, the paper made a study to the application in the evaluation.

Building of Evaluation Index to Nanometer Diamond Glass. By analyzing the factors of physical properties, chemical properties, processing characteristics, material appearance, and tactile experience, psychological attributes, and price factors, and environmental factors, the paper established of materials evaluation indicators, as shown in Figure 1.

Evaluation to the Material of Gray Theory. Grey system theory means that the system is order and whole function, although its behavior unclear, the data is complex. The theory takes small sample, dim information, and uncertainty system as the object of study. By analyzing the known information about the generation, development, the theory extracts the valuable information and makes the gray system of the factors from dim to clear, from little to more, and make the correct understanding and effective application to the system [5].

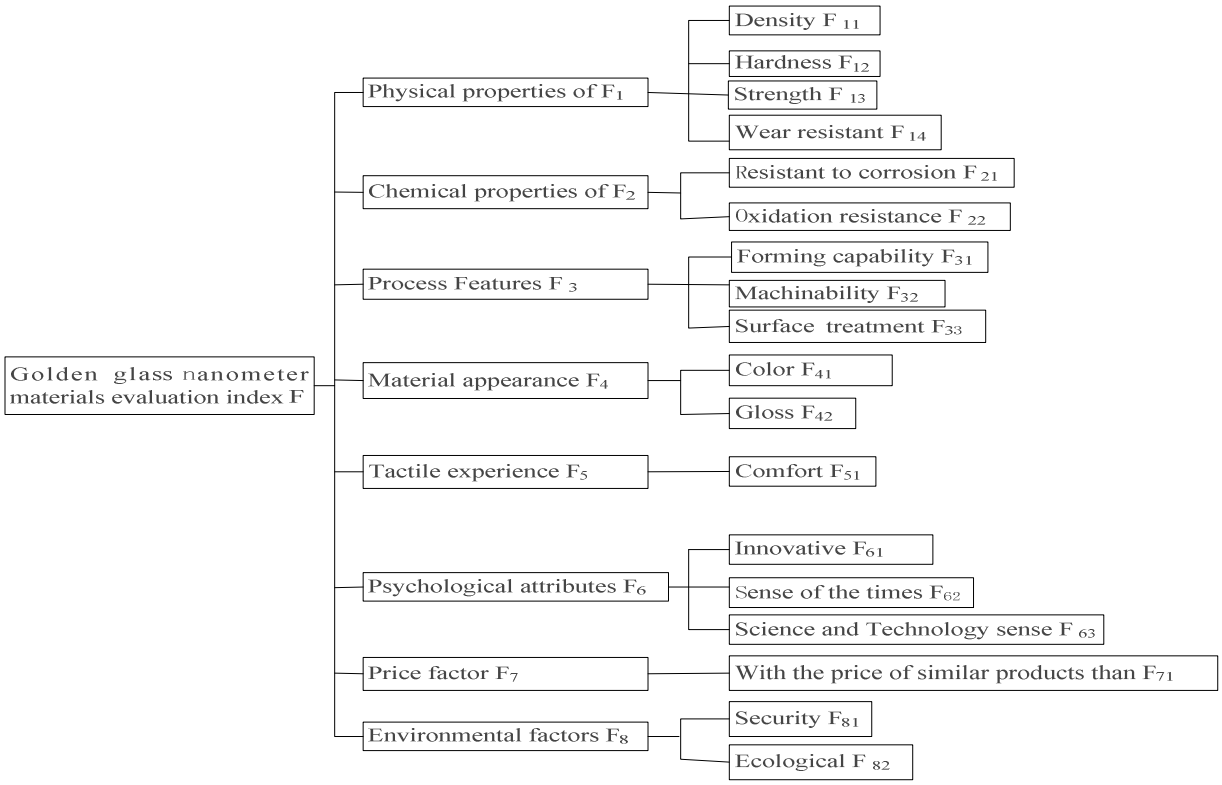

Fig.1 Evaluation index of nanometer diamond glass

The evaluation indicators at different levels are divided into 7 classes. The standards of grading are drawn up with the score of 9, 7, 5, and 3. When the target level is between two adjacent levels, the score of 8, 6, 4 are defined. Invitation to 5 industrial designers is invited to make an evaluation to materials. The steps are as follows:

Identifying weight vector of evaluation indicators.

$W = (0.211,0.087,0.0\ 62,0.188,0\ .137,0.162\ ,0.050,0.1\ 03)$, $W_1 = (0.104,0.325,0.175,0.396)$, $W_2 = (0.405,0.595)$, $W_3 = (0.421,0.367,0.212)$, $W_4 = (0.356,0.644)$, $W_5 = (1)$, $W_6 = (0.335,0.431,0.234)$, $W_7 = (1)$ $W_8 = (0.591,0.409)$.

Evaluators score and establish evaluation sample matrix, as shown in table 1.

Table 1 Materials evaluation sample

	F_{11}	F_{12}	F_{13}	F_{14}	F_{21}	F_{22}	F_{31}	F_{32}	F_{33}
E_1	5	8	6	8	6	8	4	4	5
E_2	6	7	7	9	5	7	6	3	4
E_3	6	8	8	9	5	7	4	6	6
E_4	7	8	7	8	6	8	5	4	5
E_5	6	7	6	9	5	7	5	5	6
	F_{41}	F_{42}	F_{51}	F_{61}	F_{62}	F_{63}	F_{71}	F_{81}	F_{82}
E_1	7	9	7	6	7	9	4	6	5
E_2	8	8	8	5	6	8	3	8	4
E_3	8	8	6	7	6	7	3	7	6
E_4	7	9	7	7	7	9	4	8	6
E_5	6	9	7	6	5	8	4	7	5

Determine the gray class.

Set up “excellent, good, medium, poor”4 evaluation level in class. Corresponding gray number and whitening weight function is: the first gray class is “excellent”(e=1), gray number $\otimes_1 = [9,\infty]$,whitening weight function f_1; the second gray class is “good” (e=2), gray number $\otimes_2 = [0,7,14]$, whitening weight function f_2; the third gray class is “medium” (e=3), gray

number $\otimes_3 = [0,5,10]$, whitening weight function f_3 ; the fourth gray class is "poor" (e=4), gray number $\otimes_4 = [0,3,6]$, whitening weight function f_4.

Calculating the number of gray evaluation.

Evaluation of the material F11 (density) belong to class e evaluation of ash gray evaluation $X_{11e}^{(1)}$:

e=1, $X_{111}^{(1)} = \sum_{k=1}^{5} f_1(d_{11k}^1) = 3.33$; the same way: e=2, $X_{112}^{(1)} = 4.286$; e=3, $X_{113}^{(1)} = 4$; e=4, $X_{114}^{(1)} = 0.333$.

For indicators F_{11}, overall gray evaluation factor for: $X_{11}^{(1)} = X_{111}^{(1)} + X_{112}^{(1)} + X_{113}^{(1)} + X_{114}^{(1)} = 11.952$.

Vector and matrix of gray evaluation.

On the indicators F_{11}, in the first paragraph that the e evaluation of gray class of gray for evaluation $r_{11e}^{(1)}$:

$e=1$, $r_{111}^{(1)} = \frac{X_{111}^{(1)}}{X_{11}^{(1)}} = \frac{3.333}{11.952} = 0.297$; the same way: $e=2$, $r_{112}^{(1)} = 0.359$; $e=3$, $r_{113}^{(1)} = 0.335$; $e=4$, $r_{114}^{(1)} = 0.028$.

Evaluation indicators F_{11} for the gray of gray class evaluation vector:

$r_{11}^{(1)} = \left(r_{111}^{(1)}, r_{112}^{(1)}, r_{113}^{(1)}, r_{114}^{(1)}\right) = (0.279,0.359,0.335,0.028)$, the same way: $r_{12}^{(1)}$, $r_{13}^{(1)}$, $r_{14}^{(1)}$, $r_{21}^{(1)}$, $r_{22}^{(1)} \ldots r_{81}^{(1)}$, $r_{82}^{(1)}$, get gray evaluation matrix $R_i^{(1)}$.

Comprehensive evaluation to F_i:

$B_1^{(1)} = W_1 \bullet R_1^{(1)}$, $B_2^{(1)} = W_2 \bullet R_2^{(1)} \ldots B_8^{(1)} = W_8 \bullet R_8^{(1)}$.

Comprehensive evaluation to F:

$B^{(1)} = W \bullet R^{(1)} = (0.316,0.383,0.373,0.186)$.

Calculating the evaluation value.

$F^{(1)} = B^{(1)} \bullet C^T = (0.316,0.383,0.373,0.186) \times (9,7,5,3)^T = 7.948$.

The figures prove the gray comprehensive evaluation of nanometer diamond glass material value is higher and it should be used in household appliances, such as refrigerators, freezers, microwave ovens and outdoor surfaces.

Conclusion

Product forming design is based on the present and future-oriented design. In the design, selection of materials and material properties analysis become important part of product design. By evaluation of gray theory, the paper made a representative studies to the new material, and verified if the materials are suitable for product design.

Keywords: $Sr(OH)_2$,$SrCO_3$, Nanopowder, Super gravity

Abstract: $SrCO_3$ were synthesized using $Sr(OH)_2$ solution and CO2 in super gravity reactor of carbide. It studied $SrCO_3$ powder morphology by the dosage of the appearance agent Ethylene Diamine Tetraacetic Acid(EDTA), material flow and flow velocity and the speed of the rotating packed bed. Samples were characterized using X-ray powder diffraction (XRD) and scanning electron microscope(SEM). These products were found to be orthorhombic SrCO3 nanoparticles with 90–110 nm ranges.

1.Introduction

SrCO3 is an important chemical raw material, be used as additive production of color TV picture tube and as ferrite Production [1-2], small dc motor has been widely used in the production of special glass, dye, paint, fireworks, strontium and other metal strontium metal compounds [3-4]. Nanoscale SrCO3 ultrafine particles, the crystal structure of the surface electronic structure changes, the quantum size effect, small size effect, surface effect and macroscopic quantum effect, made of nanoscale SrCO3 product has high permeability, low loss, high saturation magnetization, such as performance, also used for chemical sensors [5] and [6] of catalyst

1.Introduction

$SrCO_3$ is an important material in the production of glass for color television tubes and ferrite magnets for small DC motors[1-2],and also used in the production of iridescent and special glasses， pigments,driers,paints,pyrotechnics,catalysts and chemical sensors [2].Nanoscale SrCO3 ultrafine particles made change the crystal structure of the surface electronic structure. It own the quantum size effect, small size effect, surface effect and macroscopic quantum effect.Nanoscale SrCO3 manufactured products with high magnetic permeability, low loss, high saturation magnetization intensity and other performance[3].

At present, a variety of methods for the fabrication of $SrCO_3$ such as self-assembled monolayers,ion entrapment method,hydrothermal method, micro-emulsion mediated solvothermal method,homogeneous precipitation by enzyme-catalyzed reaction, biological synthesis using the fungus fusarium oxysporum have been reported[4-5]. Du[6] reported the synthesis of mesoporous SrCO3 spheres by using SrCl2·6H2O, NaOH, and CO2 in1,1,1,3-3-tetramethyl-guanidinium lactate. This work synthesized SrCO3 nanopowder with spherical morphology in super gravity reactor using hydroxide strontium solution and CO2.This method is simple,fast,low-cost and suitable for large-scale production of $SrCO_3$ nanostructures with spherical morphology.

2Experimental

All chemicals used were analytical grade reagents and used as received without further purification. All experiments were conducted under air atmosphere.

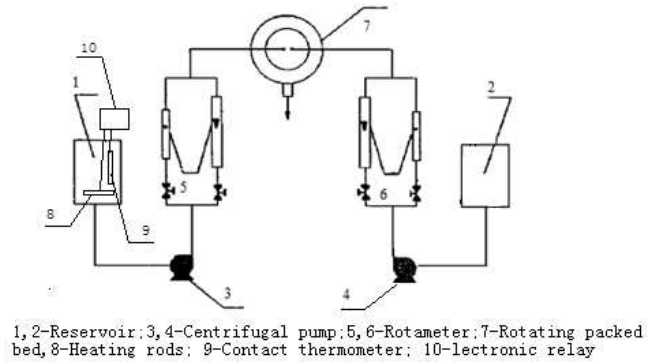

Fig.1 Diagram of experimental device

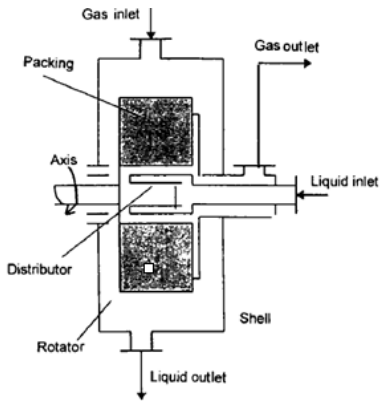

Fig.2 Schematic of rotating packed bed

Fig.1 is super gravity after reforming reactor, increasing the heater, contact thermometers and electronic relay. heating rods heat materials within the reservoir ,contact thermometer testing raw material liquid temperature snd electronic relay to control its temperature. reaction temperature is invariable and can make the uniform concentration of feed solution with no concentration gradient.Contact the temperature of the thermometer is 60 ℃ and add 1000 ml of distilled water in reservoir 1 whit turning on the electronic relay.After a certain time, the temperature of the distilled water achieve 60℃,join $Sr(OH)_2 \cdot 8H_2O$(130g) in the reservoir 1 and stir to dissolve.Solution was added EDTA(59g) after Completely dissolved Sr(OH)2 and stirring dissolved to make Configuration fluid materials.

The Sr (OH) 2 solution made from feeding pump the storage tank 1 through pump 3 by regulating the flow of rotameter 5 to control solution. It enter from figure 2 into the inlet into the rotating packed bed and carbon dioxide enter from the air tank by the pressure reducing valve flow in figure 2 to unreacted carbon dioxide vent discharge from figure 2.

FM instrument were adjusted to control the speed of the rotating packed bed after raw material into the super gravity reactor.Liquid was forced the action of centrifugal force along the packing porosity by the rotor to the rotor outer rim around the inner flow, and during time, raw material liquid are mixing reaction in packing layer. Raction products were made finally influx to the shell in the outer packing to get slurry by super gravity. Slurry was be disposed by centrifugal and washing by anhydrous ethanol.It was characterized using XRD and SEM.

2. Results and discussion

2.1 Reaction principle

Hydroxide strontium solution reacts with CO2 in the water phase and reaction is as follows:

$$Sr(OH)_2+CO_2=SrCO_3+H_2O$$

2.2 The influence of flow rate and rotating speed on nanopowder

Rotameter sets raw material liquid flow rate of 200 ml/l and CO_2 flow rate of 2 l/min adding a certain amount of morphology to react.FM frequency was 13Hz,20Hz, 25Hz, 30Hz, 35Hz and 40Hz,respectively.It corresponds to speed 780 r/min,1080 r/min,1200 r/min,1500 r/min,1800 r/min , 2100 r/min and 2400 r/min, respectively.strontium carbonate slurry was centrifugal separate by under different rotational speed to get samples that was washed by ethanol,and than ultrasonic dispersion for SEM analysis.fig. 3 was shown that from A-1 to A-5 in fig.3 was SEM analysis picture after the different rotational speed of rotating packed bed. It can draw the conclusion that the rotational speed between 780-2100 r/min get spherical strontium carbonate powder material that the granularity and the dispersivity is good. from A-6 to A-7 in fig.3 is SEM analysis of pictures,if rotating speed is more than 2100r/min, spherical particles was broken and reunited, the particle size is not uniform.The rotating bed inner pressure was increased while the rotating bed speed was increasing to lead to inner cavity by the nozzle spray sprinkled on the rotor point. The rotor circumferential velocity was increased by into liquid under the effect of the filler inside the rotor, that it can the liquid turbulent degree increases and the fluid shear force quickly. The centrifugal

force will have just generated in the process of it to the rotor outer spherical powders were shattered by subsequent liquid again with the rotating packed bed cutting of high speed spinning and scattered. Therefore, the speed of the rotating packed bed is less than 2100 r/min in the preparation of strontium carbonate powder materials.

Flow of carbon dioxide has a major impact for the strontium carbonate powder morphology. From B-1 to B-2 in fig.3 get analysis of the SEM images by hydrogen strontium oxide solution flow rate for 200ml/min, the flow rate of the carbon dioxide for 9l/min and rotating packed bed is 1080 r/min,which the spherical particles is broken and reunited, the particle size is not uniform.It do the single factor experiment to the above enumerated different rotation speed after the flow of hydroxide strontium solution for 200ml/min and the flow carbon dioxide for 9l/min. All samples was analyzed by SEM and other SEM images is without insert for limited the article number.SEM images are similar with B-1 and B-2 and to get the spherical strontium carbonate powder particles has been broken.

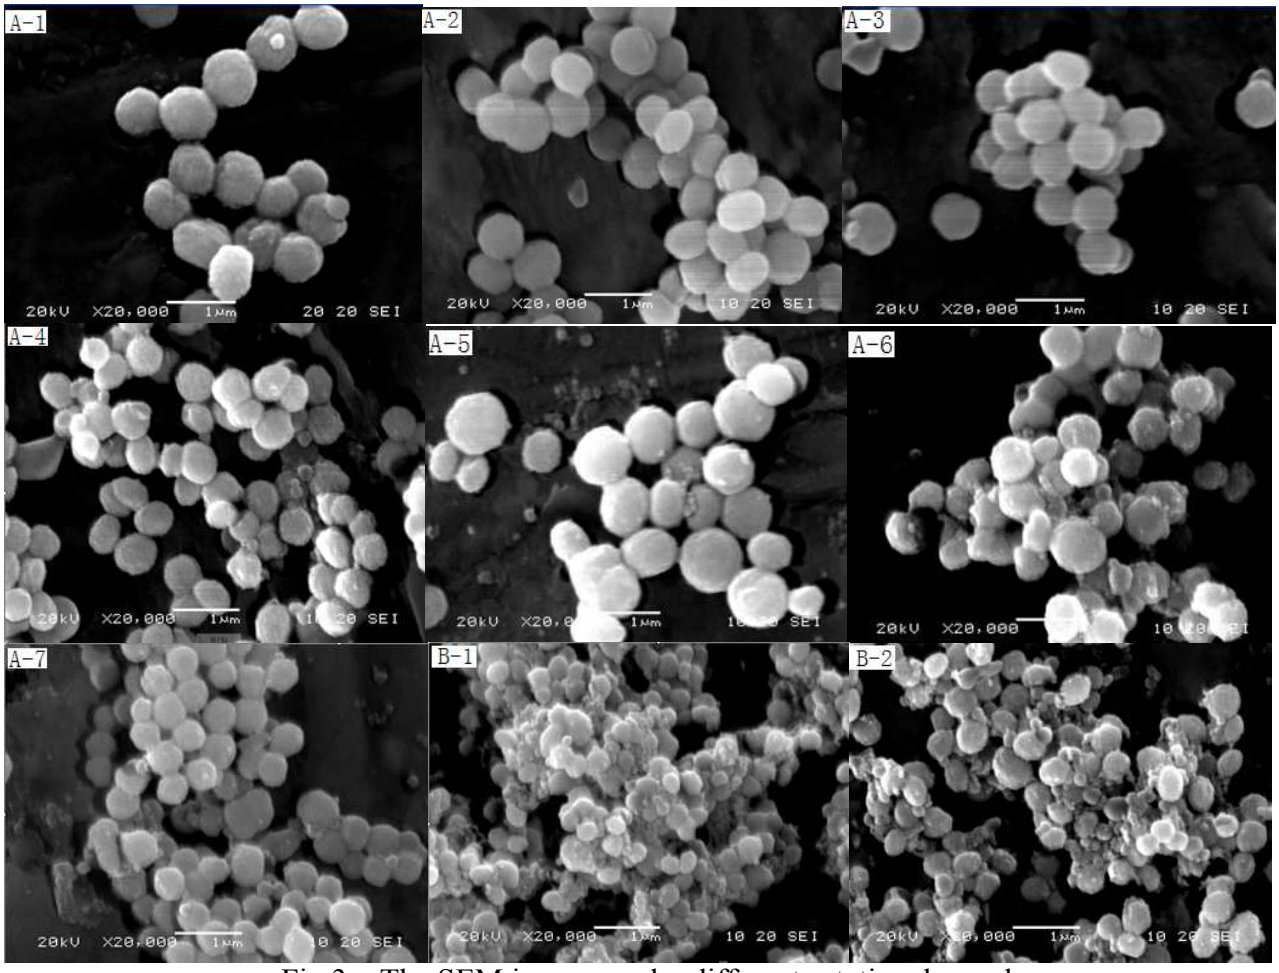

Fig.3 The SEM images under different rotational speed

2.3 The influence of morphology agent for $SrCO_3$ powder

EDTA is an effective for complexant Sr^{2+},EDTA can form the stable Sr-EDTA complexes with Sr^{2+}. Carbon dioxide react with water to form carbonic acid root when bubbled into carbon dioxide, at the same time, Sr^{2+} will release from the Sr-EDTA complexes to form SrCO3. The chemical reaction principle is as follows:

$$Sr^{2+} + EDTA \rightarrow Sr\text{-}EDTA \qquad Sr\text{-}EDTA + CO_3^{2-} \rightarrow SrCO_3 + EDTA$$

The different n_{Sr2+}/n_{EDTA} molar ratio was synthesized by hydroxide strontium solution flow rate of 200ml/l, CO2 flow rate of 2l/min and the speed of 1500 r/min to choose the mole ratio of 0.25 and 0.5 for experiments,respectively.EDTA had a greater influence on the morphology of strontium carbonate. Mole ratio was 0.25 by SEM image contrast synthetic powder morphology which was no rules. Mole ratio was 0.5 to obtain spherical nanometer strontium carbonate powder materials.

EDTA control the release rate of Sr^{2+} to contribute to separation the nucleation and growth of two phase.Mole ratio is small, which can not effectively control the release rate of $Sr2^{+}$ to lead to without separation nucleation and growth.

2.4 The XRD analysis of the sample

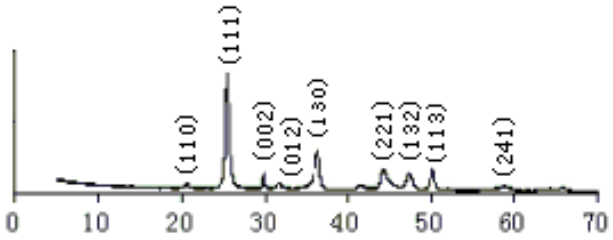

Fig.4 XRD patterns of $SrCO_3$

Typical XRD patterns of the as synthesized $SrCO_3$ nanopowder are shown in Fig.4,which is n_{Sr2+}/n_{EDTA} value equal to 0.5, the rotating speed of 1500 r/min, flow rate of 200 ml/l $SrCO_3$ solution and CO2 flow rate of 2l/min.All diffraction peaks were identified to be orthorhombic $SrCO_3$-compared to the JCPDS No. 05-0418(a=5.1039A，b=8.4022A,c=6.0210A,$\alpha=\beta=\gamma=90^{o}$). Slightly broadened diffraction peaks with 2θ(°) of 20.34, 25.39, 29.63, 31.75, 36.52, 44.47, 47.18, 50.08 and 58.63 were readily indexed as the(110), (111), (002), (012), (130), (221), (132), (113)and(241).

3 Conclusion

Spherical $SrCO_3$ nanopowder were successfully synthesized by the super gravity reactor.Raw materials is the $Sr(OH)_2$, CO2 and EDTA.For the best reaction conditions is that hydroxide of strontium solution temperature was 60℃ and the flow rate was 200 ml/min, joining n_{Sr2+}/ n_{EDTA} is equal to 0.5,the flow rate of CO_2 was 2l/min, the speed of the rotating packed bed was 1500 r/min. Samples were characterized using XRD and(SEM). These products were found to be orthorhombic SrCO3 nanoparticles with 90–110 nm ranges.

Keywords: donor unit; organic molecule; light-emitting material

Abstract. A novel electron donor unit based on phenothiazine has been designed and constructed. The target compound 10-octyl-3,7-di(thiophen-2-yl)-10H-phenothiazine was easily synthesized in high yields with a milder and efficient route via the Suzuki coupling reaction. Optical spectra show that, from the solution to the solid state, both the absorption and fluorescence spectra of the target compound are small blue-shifted. Moreover, the fluorescence spectra exhibit the emission maxima of the target compound ranging from 485 nm to 496 nm, which belongs to blue-green light region. As expected, the target compound should be a promising donor to construct D-A type materials for applications in organic light-emitting diodes (OLEDs).

Introduction

The D-A type molecules have attracted much academic and technological research attention during the past decade because of their great potential applications as photoactive materials in molecular electronics, such as biochemical fluorescent technology,[1] electrogenerated chemiluminescence,[2] organic light emitting diodes (OLEDs),[3] and photovoltaic cells.[4] Compared to other materials, the donor-acceptor materials have an advantage on their physical properties easily being tuned over a wide range by appropriate chemical modification to the structures of donors or acceptors.[5] Recently, Donor-acceptor (D-A) molecules are of great interest as light-emitting and electroluminescent multifunctional materials for organic light-emitting diodes (OLEDs).[6] To make a improvement of the property of OLEDs, the feature of emissive materials we desired should be highly capable of accepting both electrons and holes while exhibiting high luminescence quantum yield.[7] That's to say, we should explore a new molecular design approach to combine distinct electron-donating and electron-accepting units into a suitable emissive D-A molecule to improve functions of OLEDs. A plenty of carbazole, triarylamine and their derivatives have been extensively studied as electron donors in emissive materials in OLEDs.[8] Although triarylamine and carbazole designed as a donor for many D-A molecules have been explored in OLEDs, phenothiazine and phenoxazine are potentially better electron donors , due to their 0.7 eV lower ionization potentials and more stable radical cations.[9] These results motivate us to design new donors based on phenothiazine and its derivatives for D-A type materials in OLEDs.

Herein, we design and synthesize a novel donor based on phenothiazine to construct D-A type molecules through a Suzuki reaction, The optical properties in solution and in the state were characterized by means of UV-vis and fluorescence spectroscopy, which exhibit that 10-octyl-3,7-di(thiophen-2-yl)-10H-phenothiazine should be promising candidates for light-emitting diodes because of its relatively good electronic and optical properties.

Experimental Section

Characterization: ^{1}H NMR and ^{13}C NMR spectra were collected on a Bruker AM-400WB spectrometer in chloroform-d as solvent and tetramethylsilane (TMS) as the internal standard. The mass spectra were obtained by using a Bruker Daltonics Autoflex II TOF system. FT-IR spectra were

recorded using a Bruker Vertex 70 FT-IR spectrometer with samples in KBr pellets. Materials: Diethyl ether and tetrahydrofuran (THF) were dried over sodium benzophenone and distilled under argon atmosphere before use. $CHCl_3$ and DMF were dried over CaH_2 and then distilled under nitrogen atmosphere and deoxygenated by purging with nitrogen for 30 min before use in monomer synthesis. Films were easily formed by spin coating from PMMA-THF solution (1 mg ml-1, quartz substrate). Other chemicals were purchased from Acros and used without further purifications.

2.1 Synthesis of 3,6-dibromo-9-octyl-9H-carbazole 1

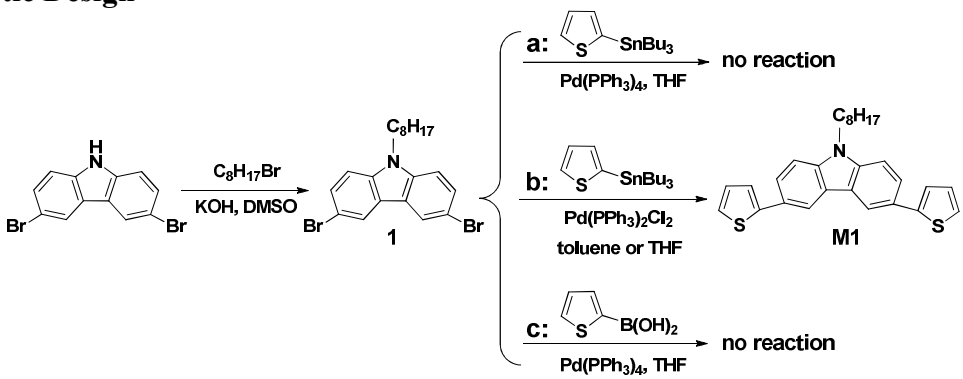
3,6-dibromo-9H-carbazole (2.0 g, 6.15 mmol) and 1-bromooctane (1.43 g, 7.38 mmol) were dissolved in DMSO (40 ml) and stirred for 30 min at room temperature, A sodium hydroxide solution (5 ml, v: 50%) was slowly added and then stirred for overnight at room temperature. Then the reaction mixture was poured into water. The precipitate was filtered, repeatedly washed with distilled water and dried under vacuum. The product was obtained as off-white solids without further purifications. Yield: 2.3 g, (86 %). 1H NMR (400 MHz, $CDCl_3$, ppm): δ= 8.08 (s, 2H), 7.48 (d, J=8.8 Hz, 2H), 7.20 (d, J=7.2 Hz, 2H), 4.16 (t, J=6.8 Hz, 2H), 1.74 (d, J=6.4 Hz, 2H), 1.23−1.15 (m, 10H), 0.79 (t, J=6.4 Hz, 3H). 13C NMR (100 MHz, $CDCl_3$): δ 138.00, 127.76, 122.27, 111.03, 109.01, 42.06, 30.69, 28.15, 27.72, 26.11, 21.54, 13.04 (ppm).

2.2 Synthesis of 9-octyl-3,6-di(thiophen-2-yl)-9H-carbazole M1

A mixture of 3,6-dibromo-9-octyl-9H-carbazole (0.50 g, 1.14 mmol), tributyl(thiophen-2-yl)stannane (1.07 g, 2.86 mmol), and $Pd(PPh_3)_2Cl_2$ (0.09 g, 0.13 mmol) in dry toluene (30 ml) was stirred at 115 ℃ under N_2 for 24 h. After cooling the mixture to the room temperature, the solvent was directly removed, The crude product was purified using column chromatography on a silica gel with petroleum ether as the eluent. The product was obtained as white solid. Yield: 0.40 g, (78%). 1H NMR (400 MHz, $CDCl_3$, ppm): δ= 8.27 (s, 2H), 7.66 (d, J=8.0 Hz, 2H), 7.30 (t, J=7.4 Hz, 4H), 7.19 (d, J=5.2 Hz, 2H), 7.04 (s, 2H), 4.22 (t, J=7.0 Hz, 2H), 1.81 (t, J=6.6 Hz, 2H), 1.31−1.15 (m, 10H), 0.80 (m, 3H). 13C NMR (100 MHz, $CDCl_3$): δ 144.54, 139.21, 127.06, 124.70, 123.37, 122.52, 122.03, 120.94, 116.90, 108.15, 42.01, 30.72, 28.30, 27.89, 26.96, 21.55, 13.05 (ppm).

Results and Discussion

3.1 Synthetic Design



Scheme 1 The synthesis of acceptor monomer **4**

The target compound M1 was synthesized via the Still coupling reaction as illustrated in Scheme 1. First, 3,6-dibromo-9H-carbazole reacted with 1-bromooctane in DMSO under a milder reaction condition and a simple purification process to give **1** in 86% yield. Then, a reaction of 3,6-dibromo-9-octyl-9H-carbazole with 3.0 equiv. of tributyl(thiophen-2-yl)stannane and $Pd(PPh_3)_2Cl_2$ as a catalyst to afford **M1** in 78% yield, which was adopted after a, b and c reaction route selections.

The organic molecule 5,5'-(9,9-dioctyl-9H-fluorene-2,7-diyl)bis(thiophene-2-carbal dehyde) are successfully synthesized over four steps from readily available starting materials, which was freely soluble in most common organic solvents so that it should be a intermediate used to form new

donor-acceptor type oligomers. In view of their relatively good electronic and optical properties, we believe such materials should be promising candidates for light-emitting diodes, field-effect transistors or photocells.

Table1 The synthesis of Compound **3**

Entry	Reagent	solvent	catalyst	Yield (%)
1	Thiophen-2-ylboronic acid	THF	$Pd(PPh_3)_4$	0
2	Tributyl(thiophen-2-yl)stannane	THF	$Pd(PPh_3)_4$	0
3	Tributyl(thiophen-2-yl)stannane	THF	$Pd(PPh_3)_2Cl_2$	48
4	Tributyl(thiophen-2-yl)stannane	toluene	$Pd(PPh_3)_2Cl_2$	78

3.2 Optical properties

The electronic spectra of the compound **M1** were recorded in THF solutions and as PMMA thin films on quartz substrates as shown in Table 2. Fig. 1 shows the UV-vis absorption spectra and fluorescence emission spectra of compound **M1** measured in THF solutions and PMMA thin films. Films were easily formed by spin coating from PMMA-THF solutions (1 mg ml^{-1}, quartz substrate). The absorption spectra (Fig. 1 a) of compound **M1** exhibit two absorption bands in solution, also reveal similar trends in the solid state. Obviously, both of them exhibit the absorption bands at 292-354 nm, which attribute to the localized π-π* transition. In both states, it cannot bring obvious shift of the absorbance band at around 293 nm. However, the absorption band in the solid state exhibit a small blue shift (10 nm), compared to the absorption band at 354 nm in solution. Optical band gaps (Table 2) in solution and solid state were approximated by extrapolation of the low-energy side of the absorption spectra to the baseline.[10] In our expectations, the energy band gaps of compound **M1** is similar, either in solution or in the solid state.

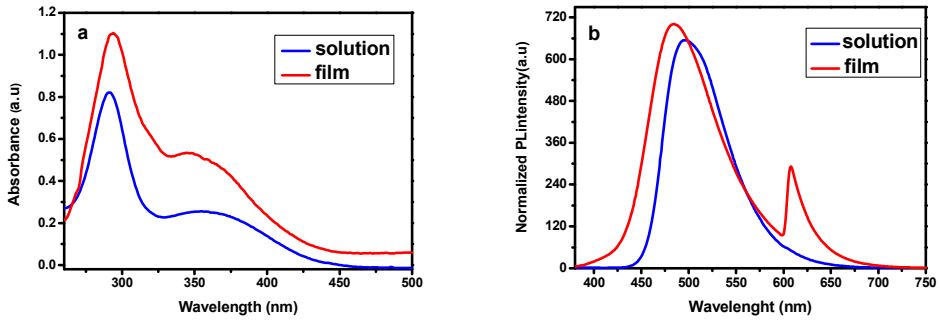


Fig. 1 (a) Absorption and (b) fluorescence spectra of compound **M1** in THF (10^{-5} M) and in PMMA-film.

Table 2 Optical data for compounds **M1**

	Solution				**Film**[d]			
Compds	λ_{abs}[a] /nm	λ_{lum}[b] /nm	Stokes shift/nm	λ_{onset}[a] /nm (Eg[c] /eV)	λ_{abs}[e] /nm	λ_{lum}[b] /nm	Stokes shift/nm	λ_{onset}[a] /nm (Eg[c] /eV)
3	292,354	496	142	434 (2.86)	294, 344	485,608	141	429 (2.89)

[a]Measured in a dilute THF solution (1×10^{-5} M). [b] Excited at the absorbance maxima. [c]Estimated from the onset of absorbance ($E_g=1240/\lambda_{onset}$). [d]Film were drop cast from PMMA-THF solution (1 mg ml^{-1}, quartz substrate). [e]Reported values are the absorbance maxima.

The fluorescence spectra of the compound **M1** have well-resolved vibronic structures in dilute THF solutions and in the solid states, as shown in Fig. 1b. In the solid state, the fluorescence spectra of compound **M1** exhibit an emission maxima at 485 nm with a shoulder at 608 nm, which is relatively small blue-shifted, compared with the emission maxima observed in solution. The phenomenon of blue shifts of the emission maxima is identical to the optical absorption, which could be explained by noncoplanar phenothiazine impacting the interactions between molecules (packing effect) in the solid state. Furthermore, it is obvious that the Stokes shifts of the compound **M1** are large, taking 142 nm in

solution and 141 nm in the solid state. The fluorescence spectra exhibit that the emission maxima of compound 3 from 485 nm to 496 nm belong to blue-green light range. Thus, the target compounds is expected to be a promising blue-green light-emitting material for applications in organic light-emitting diodes (OLEDs).

Conclusions

In summary, we have successfully designed and constructed a novel electron donor unit based on phenothiazine. The target compound10-octyl-3,7-di(thiophen-2-yl)-10H -phenothiazine was synthesized in high yields over three steps with a milder and efficient route via the Suzuki coupling reaction. Optical spectra show that, from the solution to the solid state, both the absorption and fluorescence spectra of the target compound are small blue-shifted. the fluorescence spectra also exhibit the emission maxima of compound **M1** ranging from 485 nm to 496 nm, which belongs to blue-green light range. In our expectations, the target compound should be a promising donor to construct D-A type materials for applications in organic light-emitting diodes. Furthermore, studies on the constructions of distinct donor-acceptor molecules for high-performance photovoltaic materials in organic light-emitting diodes are ongoing in our group, which will be reported in due course.

Key words: Intelligent materials; Self diagnosis; Adaptive; Sensor

Abstract. The background and design idea of the intelligent materials is introduced. Three elements of intelligent materials are given. Then based on classifying of intelligent materials, the features and applications of intelligent materials are researched.Principle and the latest applications of typical intelligent materials such as optical fiber, shape memory alloys, shape memory polymers, piezoelectric, magnetostrictive materials, fluid material and polymer colloid are analyzed simplely. The research difficulties and the future research focuses of intelligent material are pointed out.

Introduction of Intelligent Materials

Intelligent material is the fourth generation materials after the natural materials, polymer materials and artificial materials, it is one of the important development directions of the modern high-tech materials.Concept of intelligent materials was proposed first by Japan scientist in 1989. Intelligent material is called as sensitive material, is combined by sensor or sensing elements with traditional materials. Intelligent materials can feeling the stimuli from environmental then analysis, process, judgment and taking certain measures to moderate response.Idea of intelligent material comes from bionics, its goal is to study a "live" material with variety function similar to the biological therefore intelligent materials must have three essential elements follow as perception, drive and control.

Measure of Intelligent Materials

The measure indicator of intelligent material general used of qualitative indicator, it is measured mainly from following aspects: The perception function which can detect and discriminate outside of stimulus strength.The drive function which can response outside changes.It can select and control response according to set of way.Its reaction compared with sensitive timely and appropriate.It can quickly to recovery to original state after external stimulus elimination.

Classification of Intelligent Materials

Intelligent materials can be divided into intelligent material and non-embedded intelligent material accordance the structure. The embedded intelligent material is made by three kinds of raw materials with sensing, driving sensors and processing functions,it is embedded in the substrate material, sensor collecting and detecting the information from the external environment and control processor incentives driven component performs the appropriate action.The non-embedded intelligent material with intelligent features, can change depending on the environment and time.Intelligent material can be divided into metal intelligent materials, inorganic non-metallic intelligent materials and polymeric intelligent materials according to the sources. Intelligent materials can be divided into optical fiber, shape memory alloys, piezoelectronic materials, magnetostrictive materials and electrostrictive materials etc. according to their different functions. According to the composition of structure intelligent materialscan be divided into driven materials, sensitive materials, substrate material and so on[1].

Function of Intelligent Materials

Intelligent materials have the following functions:A.Sensing function when used as a sensor, it is able to perceive the information from outside or their environmental conditions such as load, stress, strain, vibration, thermal, light, electromagnetic, chemical, nuclear radiation intensity and its variation.B.Feedback function when used as a feedback device,it can compare input information with output information of the system by sensing networks and provide the results to control systems timely and accurately.C.Information identification function and accumulation function,it can identify various types from sensing networks and accumulate the information.D.Response function, it has drive function, according to the external environment and internal conditions change, to make an appropriate response in time dynamically, select and control the response according to the setting of set way and take the necessary action.E.Self-diagnosis function,it can self-diagnose a series of issues such as system failures and misjudgments and correct the issues through comparison and analysis the current situation with the past situation of the system.F.Self-recovery function,it can fix some local damage or destruction after an external stimulus eliminated, and can be quickly restored to its original state through self-breeding, self-growth, in-situ composite mechanism.G.Self-adjusting functions,it can adjust its structure and function automatically in a timely and change their status and behavior, according to the changing external environment and conditions, make material system in an optimal way to proper response to external changes.

Application of Intelligent Materials

Intelligent material is a complex material of system, it collects materials, structures, intelligent processing, implementation systems, control systems and sensing systems in one. Intelligent materials mainly used in the following areas.A.Building area[2]. The fiber with "self-healing" function can feel the information from cracks in concrete and steel corrosion and can bond the cracks in concrete or block the corrosion on reinforcing steel bar automatically.Fiber for binding cracks is made of glass-fiber and polypropylene porous hollow fibers, after mixed in concrete, when it excessive flexed in concrete and is ripped, thereby release chemicals to filling and bonded cracks in concrete.Anticorrosion fiber is placed around steel, when the acidity around the steel reaches a certain value, the fiber coating will be dissolved and release some substances from the fibers to prevent the steel in concrete.B.Aircraft manufacturing.Intelligent materials with "adaptive" function can make a flying aircraft when encounter the vortices or gust, in intelligent materials of wing drive deformation and make the wing shape changes, thus eliminating the effect of vortices or gust, to fly aircraft is able to maintain a steady state. Damage assessment and life prediction of aircraft can be self diagnostic monitoring systems, can judge cumulative damage and structural damage for themselves suddenly, according to the aircraft flight experience and injury data forecast the life of aircraft structures,in the case of security,reduces the grounding repair times and routine maintenance costs significantly, increases the economic benefits of commercial aircraft finally.C. Medical field.Intelligent materials and structures can be used manufacturing artificial limbs with a sense response without the motor control, imitate the smooth movement of muscles of the human body, make use of controllable shape recovery force of intelligent materials, grabs the fragile items deftly.Polymeric intelligent materials with "automatically administer drugs" function can administer drugs automatically according to glucose concentration of human blood.When the glucose concentration is too low, polymers would have collapsed into a small ball, insulin is sealed inside the ball; when glucose concentration at the high level the ball will stretch ribbon, the insulin sealed in small ball is released into the blood, so that the body's blood sugar level is always kept at normal level.D.Military field.Nuclear explosive optic fiber sensors and X-ray optic detectors implanted in the skin of aircraft, can real-time monitoring and early warning of enemy threat, therefore can improve the ability to resistant damage of weapons platform. Intelligent materials can also reduce noise in military systems, intelligent materials coated on the submarine can reduce noise for 60dB and submarine detection time is reduced for100 times.

Design Ideas of Intelligent Material

Design ideals of intelligent materials are relative with the following factors: material development history, influence of artificial intelligent computer, intelligent materials manufacturing, software function material, material aspirations, energy delivery, materials with the timeline. Development and design ideas of intelligent materials should start from two different views, one is the bionic technology, another is structures characteristic of the intelligent material itself.A.Bionic technology.Due to the organism has environmental perception and response, it provides a blueprint for intelligent material design. Intelligent is a characteristic of organisms, the environmental perception and response inspire to explore the adaptive of material systems and structures from bio-science, bio-engineering and approximation to multiple functions of the organism.B.Structure feature of intelligent material itself.Intelligent material structure of total regular is found from the structure characteristics of the intelligent material itself, thus synthesis, processing, design of different properties intelligent materials. Mesoscope dimensions structure plays an extremely important role in the development of intelligent materials, it is a size structure from nanometer to micron, such as the people most familiar with the proteins and enzymes, has a very important physiological function, it belongs to the nano-size of structure material.

Typical Intelligent Materials

At present, intelligent material has been widely used, has formed a separate system according to its intelligent functions. Typical intelligent materials mainly include:optical fiber, shape memory alloy,shape memory polymer,piezoelectronic material,magnetostrictive material, electro-rheological material and polymer colloid.A.Optical fibre.It is used in optical fibers made of glass or plastic, made from the principle of total reflection of light transmission. Conduction losses are far below the wires of the light transmission, therefore,it can be applied in long distance information transmission.B.Shape memory alloys[3].It is heated to a critical temperature above for shape memory heat treatment, formed martensite phase after rush cold, then exert a deformation, shape memory alloy is heated to critical temperature above again, makes crystal phase reverse shift, make the cryogenic martensite phase inverse becomes high temperature austenitic phase and recovery to inherent shape before deformation or return to martensite phase through internal elastic energy is released in follow-up cooling.C.Shape memory polymers[4].It is using modern high-molecular theory in physics and polymer synthesis and modification, molecular combinations of common polymer materials acquired and modified polymers of the kind, with characteristics of plastic and rubber. The relationship between polymer deformation and temperature (refer with Fig.1); the stress-strain curve of high elastic deformation(refer with Fig.2).D.Piezoelectronic material[5].It is a material with piezoelectrnoic effect. When a mechanical deformation is exerted on piezoelectronic materials, an electromotive force is produced in its internal, when the voltage is applied, materials produces a mechanical deformation and change size.Piezoelectronic materials includes piezoelectronic crystal, piezoelectronic fiber,piezoelectronic ceramics,piezoelectronic polymers, piezoelectronic composites etc.Piezoelectronic intelligent materials can be rapidly transformed into electrical signals or transforming the electrical signal into a vibration signal[6].E.Magnetostrictive materials.It is a material within the small magnetic domain deflected by external magnetic field and thereby causing material along the direction of the magnetic field orientation contingency stretch.F.Electro rheological materials.It is a suspension system comprised of electrolyte particles with high dielectric constant and low conductivity spread in insulating liquids of low dielectric constant, it can respond and reversible electric field rapidly.G.Aggregate colloid.It is a homogeneous mixture,it contains two different phases substance,dispersed and continuous. Former is made of tiny particles or droplets, 1~100nm in diameter; the latter is a continuous state of liquid.Aggregate colloid is polymers as the main components which is a typical of the intelligent polymer materials.Chemical energy transformed into mechanical energy to each other in aggregate colloid.

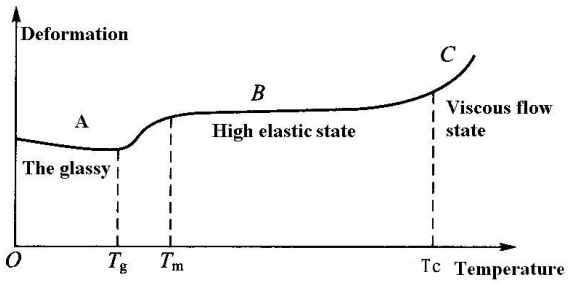

Fig.1. Relationship between polymer deformation and temperature

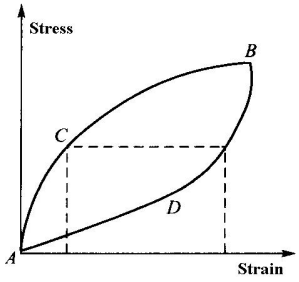

Fig.2. Stress-strain curve of high elastic deformation

Conclusion

Development and widely application of intelligent materials will result in a major revolution in materials science. Intelligent material is an open system that relies on continuous input energy or substance to dynamically adjust the adaptive capacity of outside from the surroundings to maintain its activity similar to organisms, therefore, the primary research difficulty of intelligent materials is energy conversion and storage; another difficulty is that upgrades ability of intelligent materials such as self learning, self judgment and self upgrade. Intelligent materials research focuses on the following aspects future: study of bionics theory on conceptual design of intelligent materials; study of intelligent material intrinsic properties and evaluation system of intelligent quotient; study of dissipative structure theory applied in intelligent materials; principles of complex integration and design theory of intelligent materials; nonlinear theory of integrated intelligent structure; humanoid intelligent control theory.

Keywords: carbazole unit; donor-acceptor; molecule; organic light-emitting

Abstract. A novel D-A type molecule based on carbazole central core and aldehyde terminal groups has been designed and synthesized. Optical properties of the resulting compounds were examined by means of UV-vis and fluorescence spectroscopies. It shows that, the absorption and fluorescence spectra of M2 are large red-shifted relative to M1 in both states, whereas the absorption maximum and emission maxima of M1 and M2 are small blue-shifted, from solution to the solid state. The fluorescence spectra exhibit that the emission maxima of the compounds which range from 419 nm to 472 nm belong to blue light region. As expected, the target compounds should be a promising pure blue light-emitting material for applications in organic light-emitting diodes (OLEDs).

Introduction

Conjugated organic polymers and molecules have attracted a variety of attention during the past decade due to their potential optoelectronic applications in organic light-emitting diodes (OLEDs), organic field effect transistors (OFETs) and organic photodiodes (OPVs) etc.[1] Organic molecules are of great advantages on their clear molecular structure, fixed molecular weight and higher purity, which receive a significant amount of interest by researchers currently.[2] Especially, those with donor-acceptor (D-A) architectures, play an key role in organic materials leading to desirable semiconductor properties for electrical and optical applications. As a result of their properties easily being tuned over a wide range by appropriate chemical modification to the structures of donors or acceptors, donor-acceptor (D-A) organic molecules could be used as light-emitting materials for organic light-emitting diodes (OLEDs).[3] These materials we desired should be donor-acceptor materials that combine high fluorescence quantum yields with low ionization potential or high electron affinity. Thus, exploring new synthesis and investigation of conjugated D-A molecules are essential to improve the electronic and optoelectronic properties of these materials and turn improvement of the performance of the devices.[4]

Conjugated donor-acceptor molecule systems based on thiophene, carbazole, fluorene, or phenothiazine are among the most promising materials for the development of new generation, highly efficient OLEDs devices.[5]

Carbazole and its derivatives, due to their properties of rigid plane, long conjugation length, good hole transporting properties and charge transporting compounds creating free carriers in the visible region through the photo-carrier generation process, are usually chosen to construct donor-acceptor (D-A) organic molecules used in OLEDs.[6] In the context of these, it affords us a motivation to design new molecules based on carbazolyl groups for OLEDs applications.

In this article, we design and synthesize a novel conjugated organic molecule based on carbazole unit as a donor and aldehyde groups as an acceptor to investigate electronic and optical properties of light-emitting materials in OLEDs. The optical properties in solution and in the state were characterized by means of UV-vis and fluorescence spectroscopies, which exhibit that the target compounds should be promising candidates for organic light-emitting diodes because of their relatively good electronic and optical properties.

2 Experimental Section

Characterization: ^{1}H NMR and ^{13}C NMR spectra were collected on a Bruker AM-400WB spectrometer in chloroform-d as solvent and tetramethylsilane (TMS) as the internal standard. The mass spectra were obtained by using a Bruker Daltonics Autoflex II TOF system. FT-IR spectra were recorded using a Bruker Vertex 70 FT-IR spectrometer with samples in KBr pellets. Materials: Diethyl ether and tetrahydrofuran (THF) were dried over sodium benzophenone and distilled under argon atmosphere before use. $CHCl_3$ and DMF were dried over CaH_2 and then distilled under nitrogen atmosphere and deoxygenated by purging with nitrogen for 30 min before use in monomer synthesis. Other chemicals were purchased from Acros and used without further purification. Films were easily formed by spin coating from PMMA-THF solution (1 mg ml^{-1}, quartz substrate). Other chemicals were purchased from Acros and used without further purifications.

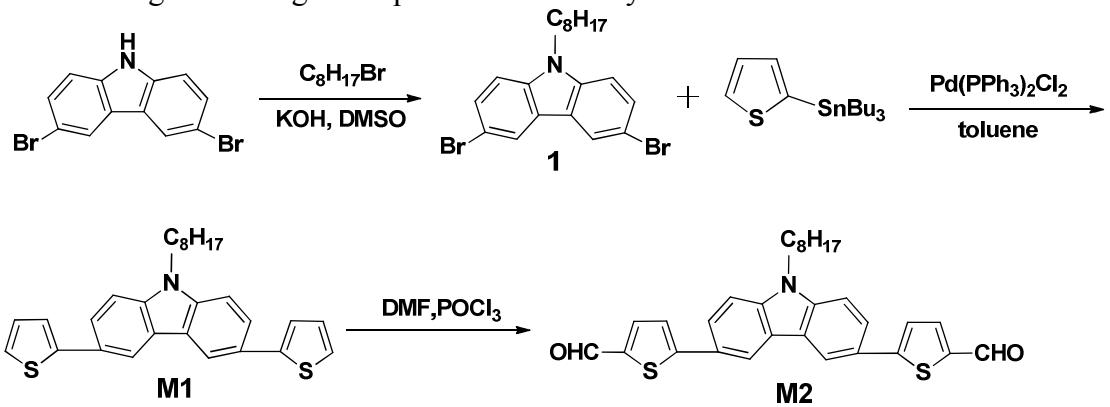
Synthesis of 5,5'-(9-octyl-9H-carbazole-3,6-diyl)bis(thiophene-2-carbaldehyde)(M2)

9-octyl-3,6-di(thiophen-2-yl)-9H-carbazole (0.84g, 1.89 mmol) and DMF (4.0 ml) was dissolved in 1,2-dichloroehane (30 ml) and Phosphorus oxychloride (6 ml) was added dropwise, keeping the reaction temperature below 5 ℃ . After $POCl_3$ added completely, the reaction solution was stirred at reflux for 12h. Then the mixture was poured into a cooled saturated sodium bicarbonate solution, neutralized with odium bicarbonate solution, extracted with dichloromehane and washed with saturated brine. The organic layer separated and dried over anhydrous magnesium sulfite. The crude product was purified using column chromatography with petroleum ether/dichloromethane (11:1, v/v) as the eluent. The product was obtained as yellow solids. Yield: 0.8 g, (84%). 1H NMR (400 MHz, $CDCl_3$, ppm): δ= 9.89 (s, 2H), 8.39 (s, 2H), 7.79 (d, J = 10.1 Hz, 4H), 7.54–7.34 (m, 4H), 4.29 (t, J = 6.6 Hz, 2H), 1.87 (s, 2H), 1.43–1.17 (m, 10H), 0.85 (t, J = 6.2 Hz, 3H). 13C NMR (100 MHz, $CDCl_3$): δ 181.57, 154.67, 140.52, 136.80, 123.97, 122.16, 117.65, 108.74, 42.50, 30.73, 29.90, 28.26, 26.23, 21.56, 13.03 (ppm).

3 Results and Discussion

3.1 Synthetic Design

In our previous report, compound M1 has been synthesized in an acceptable yield via the Still coupling reaction after multiple reaction route selections. In this article, we construct the target compound M2 by using compound M1 as the raw material via the Vilsmeier-Haack reaction, as illustrated in Scheme 1. Firstly, a reaction of 3,6-dibromo-9H-carbazole with 1-bromooctane in DMSO under a mild reaction condition and a simple purification process gave 1 in 86% yield. Then, 3,6-dibromo-9-octyl-9H-carbazole and 2.5 equiv. of tributyl(thiophen-2-yl)stannane reacted in toluene used $Pd(PPh_3)_2Cl_2$ as a catalyst to afford M1 in a yield of 78% . In the last step, DMF and $POCl_3$ were used to give the target compound M2 in 84%yield.



Scheme 1 Synthesis of compound M1 and M2

The target compound M2 5,5'-(9-octyl-9H-carbazole-3,6-diyl)bis(thiophene-2- carbaldehyde) was successfully synthesized from readily available starting materials, which was freely soluble in most

common organic solvents so that it could be a promising candidate for organic donor-acceptor type materials, so as to explore their electronic and optical properties for light-emitting diodes.

3.2 Optical properties

The electronic spectra of compounds M1 and M2 were recorded in THF solutions and as PMMA thin films on quartz substrates as shown in Table 1. Fig.1 and Fig.2 show the UV-vis absorption spectra and fluorescence emission spectra of M1 and M2 measured in THF solutions and PMMA thin films. Films were easily formed by spin coating from PMMA-THF solutions (1 mg ml^{-1}, quartz substrate). The absorption spectra (Fig.1a) of M1 exhibit three absorption bands in both solution and solid state, the absorption band ranges from 257 nm to 313 nm is attributed to the localized π-π* transition. However, the absorption spectra (Fig.2a) of M2 exhibit only one obvious absorption band in both states, the absorption band at 393-395 nm is assigned to an intramolecular charge transfer (ICT) between the aromatic ring donor part and the acceptor end groups.[7] Compared with M1 in solution and in the solid state, respectively, M2 exhibits a large bathochromic shift (81 nm and 82 nm) of the absorbance maximum (Fig.1a, Fig.2a), which is resulted from aldehyde groups taking part in the conjugation as an electron-withdrawing unit and the great stabilization of the LUMO by the electron-withdrawing groups.[8] Furthermore, both M1 and M2, from the solution to the solid state, it cannot bring large shift of the absorbance band. Optical band gaps (Table 1) in solution and solid state were approximated by extrapolation of the low-energy side of the absorption spectra to the baseline.[9] In our expectations, the energy band gaps of compounds decrease in the order, M1>M2, either in solution and in the solid state.

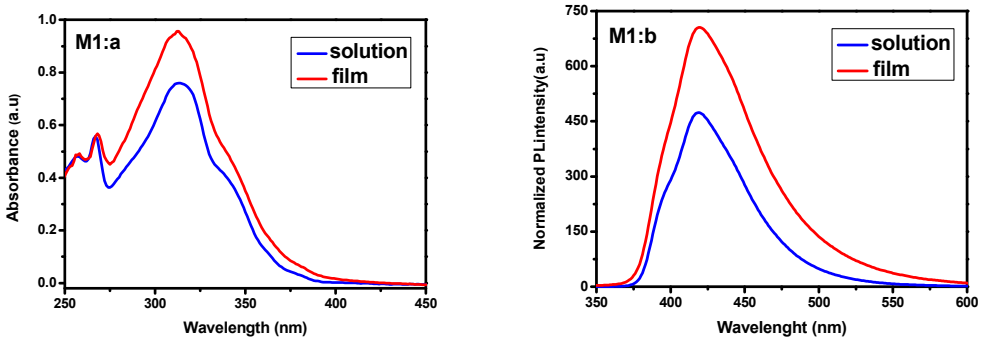


Fig. 1 (a) Absorption and (b) fluorescence spectra of M1 in THF (10-5 M) and in PMMA film.

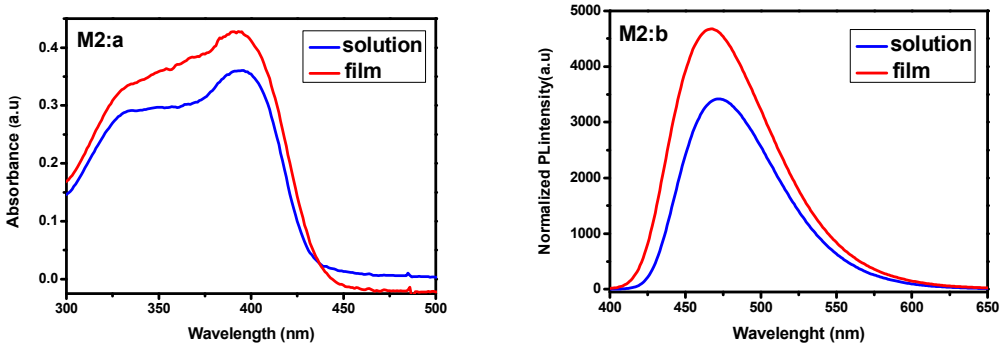

Fig. 2 (a) Absorption and (b) fluorescence spectra of M2 in THF (10^{-5} M) and in PMMA film.

The fluorescence spectra of the compounds have well-resolved vibronic structures in dilute THF solutions, as shown in Fig.1b and Fig.2b. The fluorescence spectra of M2 exhibit an emission maxima at 472 nm, which is relatively large than that of M1. Meanwhile, a bathochromic shift (48 nm) of emission maxima of M2 is more clearly observed in the solid state (Fig.1b and Fig.2b). The phenomenon of bathochromic shifts of the emission maxima is identical to the optical absorption in both states. It is easily obtained that the Stokes shifts of the compounds are relatively large, ranging

from 77 to 106 nm in solution and from 74 to 105 nm in the solid state. Not only M2 has the smallest Stokes shift and M1 has the largest one, either in solution or in the solid state, but also the Stokes shifts of both M1 and M2 in solution are larger than that in the solid state. The reason could be that the dipole moment of M2 in the solid state is much smaller than that of M1 in solution, and the emitting state of the later would be more stabilized by the ICT.10 From the solution to the solid state, the absorption and fluorescence spectra of the compounds are close and some are even blue-shifted (Table 1), which could be explained by the fact that the octyl side chain in the 9-position of the carbazole rings is not optimum charge transport in the solid state.11 The fluorescence spectra exhibit that the emission maxima of M1 and M2 from 419 nm to 472 nm belongs to blue light region. Thus, the target compounds are expected to be promising pure blue light-emitting materials for applications in organic light-emitting diodes (OLEDs).

Table 1 Optical data for compounds 3 and 4

Compds	**Solution**				**Film**[d]			
	Stokes λ_{onset}[a] /nm				Stokes λ_{onset}[a]/nm			
	λ_{abs}[a] /nm	λ_{lum}[b] /nm	shift /nm	(Eg[c] /eV)	λ_{abs}[e]/nm	λ_{lum}[b]/nm	shift /nm	(Eg[c]/eV)
M1	257,267, 313	419	106	375 (3.31)	258,268, 312	419	105	375 (3.31)
M2	395	472	77	432 (2.87)	393	467	437	437 (2.84)

a Measured in a dilute THF solution (1×10-5 M). b Excited at the absorbance maxima. cEstimated from the onset of absorbance (Eg = 1240/λonset). d Film were drop cast from PMMA-THF solution (1 mg ml-1, quartz substrate). e Reported values are the absorbance maxima.

4. Conclusions

In summary, we have successfully designed and constructed a novel D-A type molecule based on carbazole central core as an electron donor and aldehyde terminal groups as an electron acceptor. The target compound M2 5,5'-(9-octyl-9H-Carbazole- 3,6-diyl)bis(thiophene-2-carbaldehyde) was synthesized via the Vilsmeier-Haack reaction from readily available starting materials. Optical properties of the resulting compounds were examined by means of UV-vis and fluorescence spectroscopies. It shows that, the absorption and fluorescence spectra of M2 are large red-shifted relative to M1 in both states, whereas the absorption maximum and emission maxima of M1 and M2 are small blue-shifted, from solution to the solid state. The fluorescence spectra exhibit that the emission maxima of the compounds which range from 419 nm to 472 nm belong to blue light region. As expected, the target compounds should be a promising pure blue light-emitting material for applications in organic light-emitting diodes (OLEDs) and further experiments on electroluminescent properties and film morphology are in progress.

Keywords: Grain growth; WC–Ni_3Al; Grain shape; Sintering

Abstract. Growth behavior of WC grains with two different sizes of 10 μm and 4 μm in the same liquid matrix has been studied in the WC–40vol.%Ni_3Al system. The samples were sintered under a carbon saturated condition. Surfaces of the coarse WC grains are strongly micro-faceted and stepped. With the increase of sintering time, the average size of the fine WC grain increases continuously and very large plate-like triangular prismatic WC grains appear. The present investigation thus shows that the growth behavior of fine WC grain is affected by lower solubility of W in Ni_3Al matrix and the abnormal growth of WC grains is suppressed. However, the growth behavior of coarse WC grain is governed only by the difference in energy between the facets.

Introduction

WC-Co cemented carbides [1] are the most important commercial grades of WC cemented carbides, which are widely used in metal cutting, molds, mineral and petroleum industries. However, the favorable mechanical properties of WC-Co cemented carbides are significantly degraded at elevated temperature. Moreover, WC-Co cemented carbides exhibit poor resistance to corrosion resistance in aqueous and acidic environments. Meanwhile elemental cobalt has environmental toxicity when present as fine particulates.

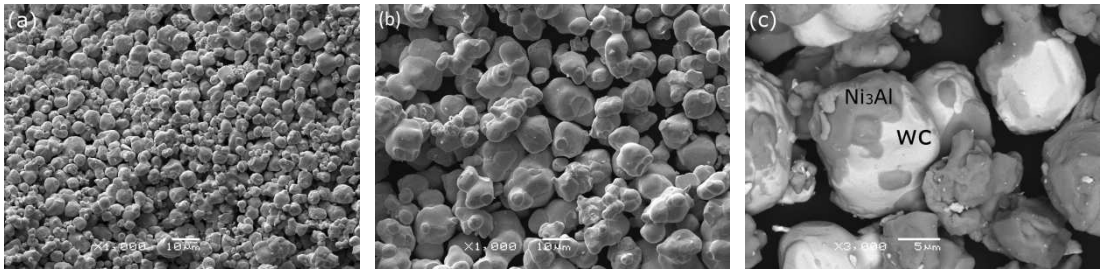
As we all know, the improved properties [2] of hard metals can be achieved by appropriate modification of microchemistry (e.g. the composition of the binder), besides optimizing of the microstructure (e.g. the WC grain size). In order to overcome the shortcomings of WC-Co cemented carbide, recently, Ni_3Al has attracted considerable attention among intermetallic compounds as the new potential binders in WC-based composites due to their certain combination of properties [3-5] such as strength increasing with temperature rising to a maximum at 700-800 ℃, good oxidation resistance and good resistance to aqueous acidic corrosion environments. Thus significant research efforts [3, 5-8] have been made to replace Co with Ni_3Al as the binding metal and some helpful property data have been obtained. Nevertheless the mechanism of WC morphology transformation is still not clear.

As we all know, the WC grain shape is an important parameter to control during sintering since it influences the mechanical properties of the tools. However, little experimental work has been devoted to the effect of the Ni_3Al binder on the WC morphology in WC-Ni_3Al composites. Any theoretical or experimental data should help in understanding the factors influencing the WC morphology during sintering. In this work, the morphology of WC grain is examined in WC-36 vol% Ni_3Al alloy with different sintering time.

Experimental

The starting materials were medium WC powders (4 μm), coarse WC powders (10 μm) and the homogeneous WC+Ni3Al (20 μm) prealloyed powders, as shown in Fig. 1. The WC+Ni3Al prealloyed powders were produced in vacuum heat treatment furnace by reaction synthesis of pure carbonyl Ni, analytical reagent Al and WC powders (10 μm) at 1100-1200℃ using the processing

conditions described in detail in Ref.[9]. Conventional Co powders (1.5 μm) were adopted in this study.



(a) medium WC powder, (b) coarse WC powder, (c) WC+Ni3Al prealloyed powder.

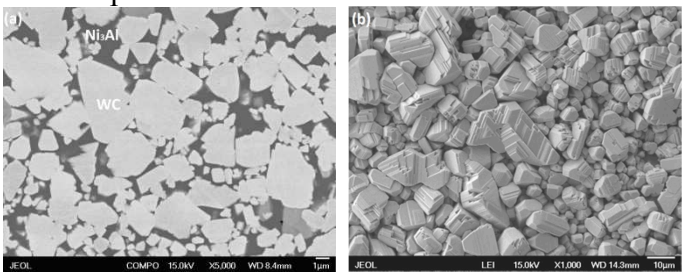
Fig.1. SEM images

Powder technology was used to manufacture the WC-36 vol% Ni3Al composites. Since the medium-grain powders tend to grow stronger than coarser-grain powders, in order to promote WC grain growth and obtain better observation, coarse WC (10 μm) and medium WC (4 μm) particles were used simultaneously in the weight ratio of 2:1. The starting materials were milled in ethyl alcohol in a ball mill at the ball-to-powder ratio of 4:1 for 24 h. WC-6 wt%Co balls with Φ10×20 mm were used. The powder mixture was dried under vacuum at 85 ℃ and sieved. The samples were uniaxially cold pressed to bars of 25×8×6.7 mm at pressure of 100 MPa, and then sintered at 6 MPa low-pressure in a sintering furnace (PVA, Germany) with graphite heating elements, for 1 h at 1450 ℃. In order to further investigate the effect of sintering time on WC grain shape, the sintered samples were re-sintered at 1450 ℃ for 8 h again.

The sintered samples were cut, ground and polished and mirror polished with diamond pastes. SEM imaging was performed on etched sections (10 wt% NaOH and K3Fe(CN)6 solution ; 20 s) using a scanning electron microscope (Model JSM-6701F, Jeol, Japan) with an X-ray energy dispersive spectroscopy (EDS) system. The chemical compositions of binder phase were characterized by energy dispersive spectroscopy (EDS). For a clear observation of WC grain shape by scanning electron microscopy, WC grains in the sintered samples were extracted by removing the binder matrix with saturation hydrochloric and Fe3Cl solution in supersonic cleaner (Branson B3500S-MT) for 5 min. The high-magnification WC morphology was measured using transmission electron microscopy (TEM).

Results and discussion

Fig. 2(a) shows the micrograph of the WC-36 vol% Ni3Al compositions sintered at 1450 ℃ for 1 h. Each microstructure belonges to two-phase region consisting of WC and binder γ. In these cases, a bimodal WC grain size distribution is formed during sintering due to two kinds of WC raw materials. WC-36 vol% Ni3Al compositions consist of faceted WC grains embedded in Ni3Al binder. Fig. 2(b) shows the results obtained from re-sintered experiments. It shows that faceted steps on the large WC grains become prevalent in Ni3Al binder.

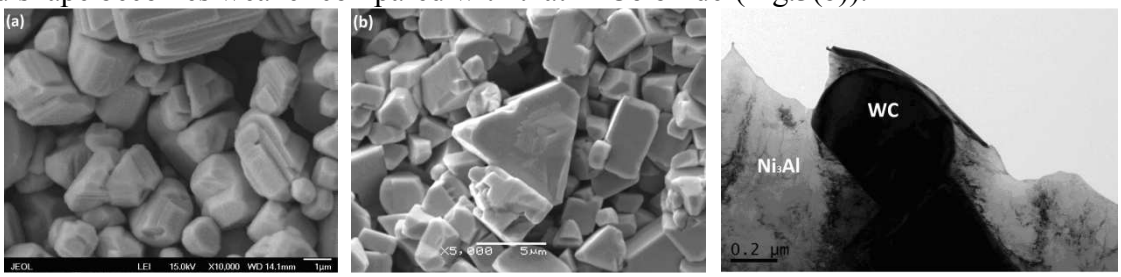


(a)1450 ℃ for 1 h, (b) 1450 ℃ for 8 h (after binder etched)

Fig.2. Micrographs of the WC-36 vol% Ni3Al composites sintered at

Fig.3 shows the WC grains extracted from the WC-36 vol%Ni3Al and WC-36 vol%Co composites sintered at 1450 ℃ for 8 h. The results in Fig.3(a) are direct evidence showing the WC grains in the Ni3Al binder exhibit distinct growth trace and the faceted steps on the surface begin to

appear. Generally, the shape of WC grain becomes rounder in the Ni3Al binder and the degree of faceted shape becomes weaker compared with that in Co binder(Fig.3(b)).



(a)WC-36Ni3Al, (b) WC-36Co. (c) TEM image of WC grains in WC-36Ni3Al

Fig.3. The WC morphology extracted from the composites with different binder metals. All the samples were re-sintered together at 1450 ℃ for 8 h(after binder etched).

Fig.3(c) shows TEM image of WC grains re-sintered at 1450 ℃ for 8 h. Generally, the WC grain in WC-Co composites has three long facets and three short facets and sharp corners. However, round grains in WC-36 vol%Ni3Al composites are more often observed in the largest grains of the Ni3Al binder alloys.

The W contents in the binder were examined by EDS. The results show that the W content in Co binder phase is approximately 22.4 wt% and that in Ni3Al binder phase is approximately 9.0 wt%. From the EDS microanalyses results obtained so far, it is reasonable to suggest that the amount of W dissolved in the Ni3Al binder metal is lower than that found for pure Co binder metal.

WC crystal has a $P_{\bar{6}}m2$ crystal symmetry [10]. The cell dimensions are a=0.2906 nm and c=0.2837 nm with c/a=0.976. The carbon atoms take the asymmetric position of (1/3, 2/3, 1/2) in the unit cell and this asymmetric occupation of carbon atoms divides the prismatic planes into two different families of planes with different atom arrangements. The structure of WC contains three kinds of dense planes formed, namely $\{0001\}$ and two different prisms planes $\{10\bar{1}0\}$ and $\{01\bar{1}0\}$.

These two families of prismatic planes can have a different affinity to carbon because W atoms on each plane have a different number of W–C bonds [11]. The planes with high affinity to carbon grow preferentially in the saturated carbon conditions and disappear finally leaving triangular prism in shape.

In case of the $\{10\bar{1}0\}$ planes all W atoms on the surface form only two W-C bonds, whereas in case of $\{01\bar{1}0\}$ planes four W-C bonds are formed on the surface. The planes with two bonds left have a higher surface energy than those with four, that is responsible for the characteristic trigonal shape of the WC formed during liquid phase sintering.

The shape change of WC grain in WC-36 vol%Ni3Al composites is possiblly attributed to the change of the solubility of W in binder. As for WC-Co cemented carbide, the carbon content in cemented carbide plays an important role on WC grain growth [12] and shape of WC [11]. However, the solubility of W in cobalt increases with decreasing carbon content and has been reported to vary, accordingly, between 2 and 15 wt% at 1250°C [13]. However, there is significantly lower solubility of W in Ni3Al in comparison with the solubility of that in cobalt [14]. The solubility of WC of Ni3Al was found to be 3-4 at.% at 1500°C [15]. It is likely that the lower solubility of W in binder will result in slowing down solution/re-precipitation processes during sintering. So the WC grain growth is inhibited and finer small WC grain will exist in Ni3Al rich binder alloys. However, when given enough sintering time, one of two families of prismatic planes will grow preferentially and/or more rapidly and the steps will form.

Conclusion

(1) The WC grains in the Ni3Al binder become rounder compared with that in Co binder. The dependence of WC grain shape on the Ni3Al content is attributed to the different solubility of W in binder.

(2) With the increase of sintering time, surfaces of WC grains are strongly micro-faceted and stepped.

Keywords: Solvothermal synthesis; Characterization; Nano melamine phosphate

Abstract. Nano melamine phosphate (NMP) flame retardant was synthesized by means of a solvothermal method, and was characterized by Fourier transform infra-red spectroscopy, X-ray diffraction, and scanning electron microscopy. Effects of reaction temperature and reaction time on the morphology of reaction products were investigated. It was observed that the morphology of the products changes greatly as reaction temperature or reaction time changes.

Introduction

There are increasingly concerns about the use of halogen-containing flame retardants because they can produce a lot of smoke and toxic gases on heating or during fires. In recent years, researchers pay more attention to intumescent flame retardation (IFR) of polymers. Generally, an IFR system usually consists of three components, i.e. an acid source, e.g. ammonium polyphosphate (APP) and melamine phosphate (MP), a carbon source, such as pentaerythritol (PER) and pentaerythritol derivatives, and a blowing agent, e.g. melamine (MEL). MP is a commonly used IFR flame retardant, and it exerts an excellent flame retardant role in many polymers, e.g. poly(vinyl alcohol), polylactide, polypropylene, polyamide, epoxy resin, and so on [1-5]. However, the particle size of the commonly used MP products is at the micro scale, and the addition of MP into polymers usually deteriorates mechanical properties of the filled polymers.

In the present work, nano melamine phosphate (NMP) was first synthesized by using a solvothermal method. To our knowledge, there are no reports on the preparation of NMP previously.

Experimental

Materials

Phosphorus acid (85%), sodium dodecyl sulfate (SDS) and benzene were all analytical reagents, obtained by Sinopharm Chemical Reagent Co. Melamine was bought from Anhui Hongsifang Company.

Synthesis of NMP

Nano MP (NMP) particles were prepared by using a solvothermal method. Firstly, melamine (12.6g, 0.1 mol), phosphorus acid (11.5g, 85%, 0.1 mol), 0.48 g SDS, and 200 ml benzene were placed in a teflon-lined cylinder (autoclave). After 30 minutes of stirring, the closed autoclave was placed inside a furnace at a preset temperature (120-180°C) and heated for 1-5 h. The chamber was left overnight to cool. The white precipitate was filtrated and washed with water. Final product was dried in a vacuum oven at 80 °C for 48 h.

Characterization

The Fourier transform infrared (FTIR) spectra of samples were recorded by using a spectrophotometer (Equinoxss/Hyperion 2000, Bruker, Gemany). The X-ray diffraction (XRD) data were obtained at room temperature by using an X-ray diffractometer (D/max2550VB3+/PC, Rigaku International Corporation). The morphology of nano powders was investigated by a scanning electron microscope (S4800, Hitachi, Japan).

Results and Discussion

Fig. 1 shows FTIR spectrum of nano MP (NMP) prepared by means of a solvothermal method at 150 °C for 3h. The peaks at 3400 cm^{-1} and 1050 cm^{-1} are the absorptions from OH. The absorptions at 3140 cm^{-1} and 1664 cm^{-1} are assigned to stretching vibration and deformation vibration of NH_2, respectively. The 1559 cm^{-1} and 1515 cm^{-1} peaks are the typical absorptions of triazine rings. The absorptions at 1245 cm^{-1}, 1100 cm^{-1} and 950 cm^{-1} are attributed to absorptions of P=O, P-O and P-OH groups, respectively [6,7].

XRD patterns of NMP are shown in Fig. 2. The main diffraction peaks at 12.2º, 19.0º, 22.2º, 24.5º, and 26.3º in Fig. 1B can be indexed as the (110), (120), (1-20), (220), and (030) planes of MP, respectively, which are in agreement with the literature (JCPDS 44-1707).

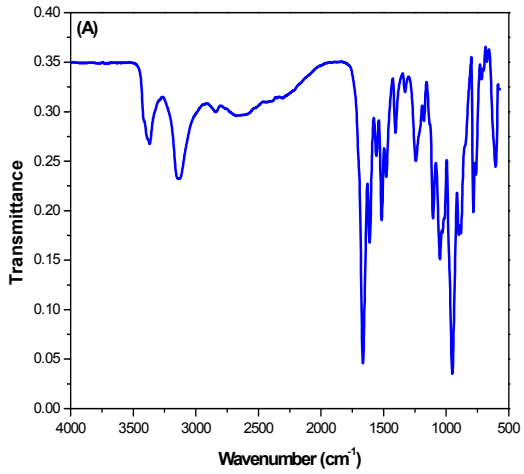

Fig.1 FTIR of NMP

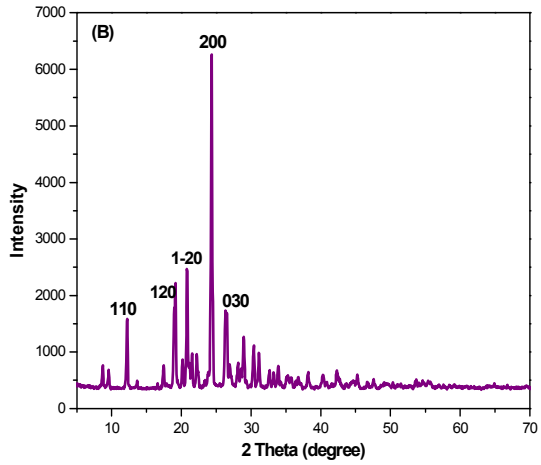

Fig.2 XRD of NMP

The morphology of the NMP particles was further observed by SEM. Fig. 3 shows the SEM images of reaction products prepared at different reaction temperatures for 3h. As can be seen from Fig. 3A and Fig. 3B, the size of particles prepared at 120 ºC and 150 ºC is at the nano scale (below 100 nm). When the reaction temperature is 180 ºC, the shapes of reaction products become irregularly rod-like and their diameters reach up to several hundred nano meters (Fig. 3C).

As for the effect of reaction time on the morphology of the reaction products, it was observed from Fig. 4A and Fig. 4B that the particle size of the products prepared at 150 ºC for 1h and 3h is also below 100 nm. A further increase of reaction time to 5h leads to a great increase particle size and a change in shape. The products become rod-like in shape, with a diameter of 100-200 nm and a length up to 1 mm as shown in Fig. 4C. Our results agree well with the previous reports where researchers in the preparation of titanium dioxide (TiO_2) nano powders by the solvothermal method found that the average particle size increased with an increase in the reaction temperature and reaction time [8,9]. In hydrothermal or solvothermal synthesis, there are many factors affecting crystal growth and morphology, such as characteristics of reactants and reaction conditions [10,11]. It was reported that the crystal growth and morphology evolution are possibly controlled by the well-known Ostwald ripening process [12], namely the dissolution of fine particles and their redeposition on larger particles. In this study, Ostwald ripening may be a dominant mechanism of the formation of NMP. At lower temperatures or shorter reaction time, the shape of NMP particles is spherical, with a diameter of about 50 nm. When the reaction temperature increases or the reaction time is prolonged, the fine spherical NMP particles may undergo aggregation due to higher free energy as shown in Fig. 4C and Fig. 4C.

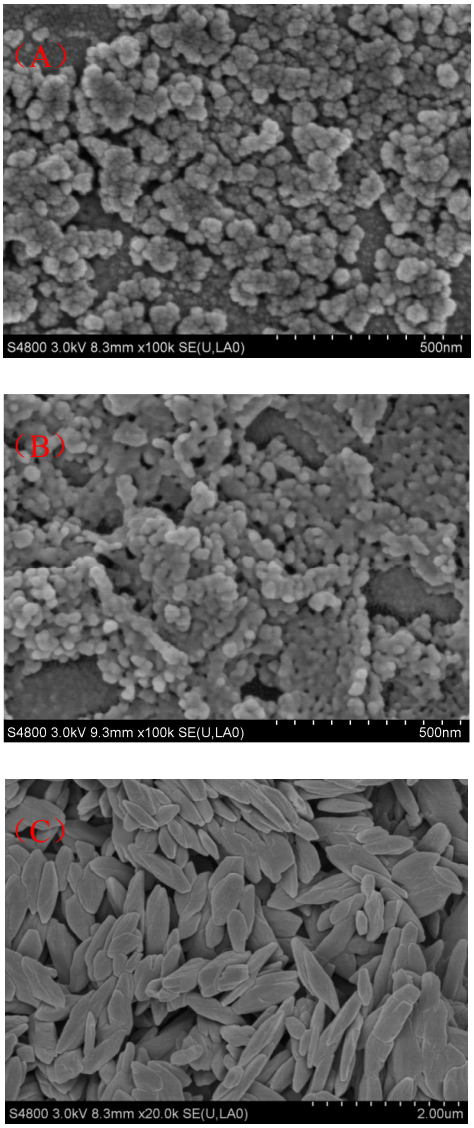

Fig. 3 SEM of MP prepared at different temperatures, (A) 120 ℃; (B) 150 ℃; (C) 180 ℃

Conclusion

In this work, nano melamine phosphate (NMP) was synthesized by a solvothermal method, and it is found that reaction temperature and reaction time have a great influence on the particle size of the product. The suitable reaction conditions for the preparation of NMP are 120-150 ºC and 1-3 h.

Preparation and Characterization of Transparent Oxyfluoride Tellurite Glass-ceramics Containing CaF_2 Nanocrystals

Zhaoxia Hou[1,a], Hangxin Li[1,b], Shaohong Wang[1], Meihan Wang[1], Xiaodan Hu[1]

[1]Liaoning Province Key Laboratory of New Functional Materials and Chemical Technology, Shenyang University, Shenyang 110044, China

[a]email:Luckyxia2007@126.com,[b]email:lihangxin@126.com

Keywords: Tellurite; Glass-ceramics; CaF_2 Nanocrystals

Abstract. Transparent oxyfluoride tellurite glass-ceramics containing CaF_2 nanocrystals were prepared by high temperature melting method. The glass-ceramics were characterized by Differential scanning calorimetry, X-ray diffraction and scanning electron microscope, respectively. The results showed that the CaF_2 nanocrystals were spherical and the average size was found to be 60 nm.

Introduction

Tellurite glasses have more advantages than silicate and borate glasses because of the physical properties such as low-melting temperature, high-refractive index, high-dielectric constant and good infrared transmissivity. Oxyfluoride Tellurite Glass-ceramics is a new type of material which based on tellurite glass and nanocrystals separated out in the substrate material. Due to the unique properties, tellurate glass-ceramics have great application potential in the fields such as pressure sensors, data storage, optical displays, optical amplifiers or as new laser hosts, optical modulators, and optical memory storage systems[1-4]. Nowadays, fluoride oxide tellurite glass and glass-ceramics become a hot research topic domestically and abroad[5-7].

Experiments

The oxyfluoride tellurite glasses used in this work were prepared with the following composition in mol%: $60TeO_2$-$15Al_2O_3$-$15CaF_2$-10NaF by using high purity TeO_2 (99.99%), Al_2O_3 (99.99%), CaF_2 (99.99%) and NaF (99.99%)) as raw materials. Batches of about 100 g of staring materials were fully mixed and melted in covered corundum crucibles at 1100 ℃ for 30 min in air. The melts were poured onto a preheated stainless steel plate followed by annealing at 200 ℃ for 2 h, and then cooled down to room temperature. The glass samples turned yellow. The obtained glass samples were then respectively polished and heat treated at 550℃ for 2 h, 3 h and 4 h to prepare transparent GC1, GC2 and GC3 samples.

GC sample	Heating temperature	Holding time
GC1	550℃	2h
GC2	550℃	3h
GC3	550℃	4h

Differential scanning calorimetry (DSC) experiment was carried out on the powder glass sample at a heating rate of 10K/min. X-ray diffraction (XRD) measurements were performed on a Philips Model PW1830 diffractometer with $CuK_{á}$ radiation. The microstructures of the samples were studied by scanning electron microscope (SEM).

Results and discussion

DSC curves were showed in Fig.1. Based on the DSC curve showed in Fig.1, there was a intense endothermic peak at 470 ℃ and exothermic peak at 550℃, so Tg(glass transition temperature) and Tx(glass crystallization temperature) were found to be 470 ℃ and 550 ℃.

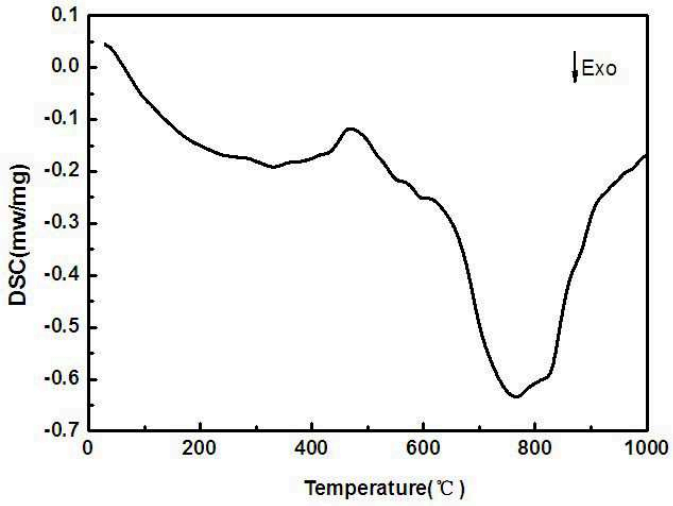

Fig.1. DSC curves of tellurite glass

It is observed that the GC1 is completely amorphous with no diffraction peaks. After crystallized by thermal treatment at 550 ℃ for 3 h or 4 h, the XRD profiles show intense diffraction peaks, which could be all assigned to the well crystallized cubic CaF_2 phases (JCPDS Card No. (35-0816)[8-9]. Diffraction peaks of GC3 are more acute than GC2.

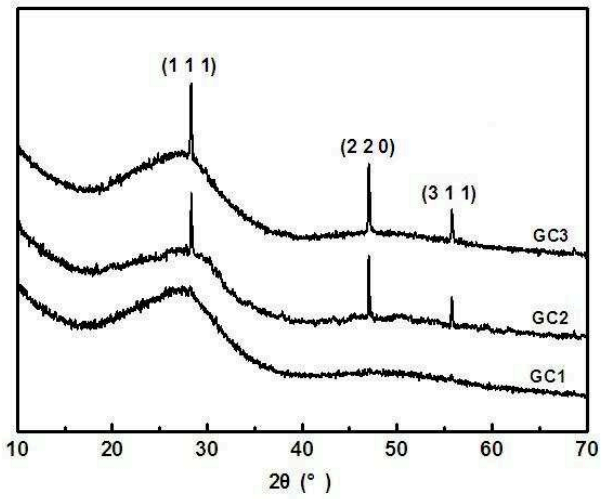

Fig.2. XRD patterns of glass-ceramics

The morphologies of GC were showed in Fig. 3. It can be seen that spherical-like parcels homogeneously dispersed in the amorphous glasses. The SEM image reveals that the nanocrystals distributed evenly in GC2 and the aggregation of nanocrystals appears in sample GC3.The average size of the nanocrystals was estimated from the line broadening of the XRD peaks and Scherrer's equation[10]:

$$d = 0.89\lambda / \beta \cos \theta_B$$

the average particle size was calculated to be 60 nm.

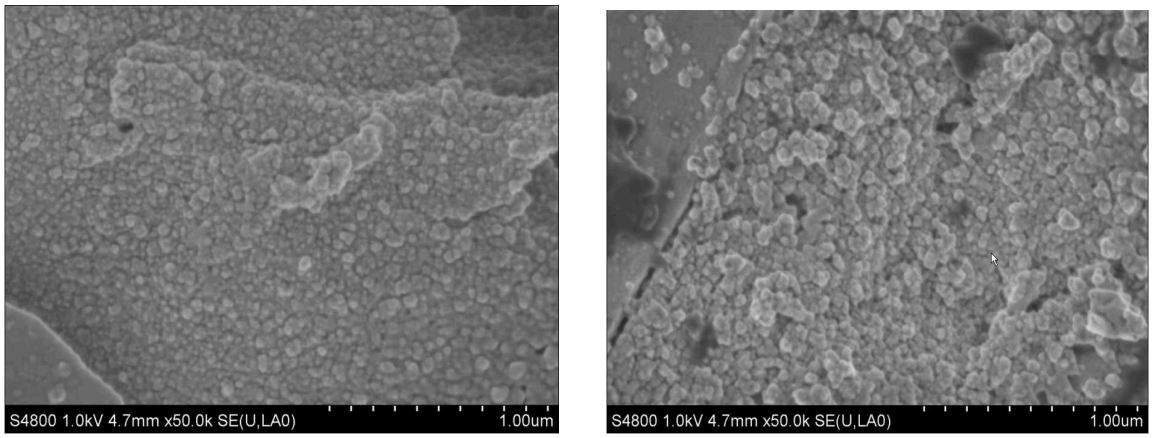

Fig.3. SEM images of sample GC2 and GC3

Conclusion

In this paper, transparent oxyfluoride tellurite glass ceramics containing CaF_2 nanocrystals were prepared by high temperature melting method. Tg(glass transition temperature) and Tx(glass crystallization temperature) were found to be 470 ℃ and 550 ℃. With the increase of the holding time, the diffraction peaks of CaF_2 nanocrystals became sharper. The nanocrystals were spherical and the average size was calculated to be 60 nm.

Keywords: Electrolysis and Plasma Polishing; Stainless Steel; Roughness; Corrosion Resistance

Abstract. Polishing was performed by using a self-made 40kw electrolysis and plasma polishing machine, and the test specimens were SUS304 stainless steel sheets. Roughness, micro-morphology, surface chemical composition and corrosion resistance of the specimens were analyzed. The results show the surface roughness value decreases quickly from R_a=0.573μm to R_a=0.115μm in first 10 minutes polishing. After 30 minutes polishing, the surface roughness value decreases to R_a=0.066μm. Microdefects on the surface are removed obtaining the smooth surface and Cr content of the surface increases slightly as well as the other elements content is nearly unchanged after the polishing, so the corrosion resistance measured by electrochemical analyzer is improved.

Introduction

Electrolysis and plasma polishing (EPP) is a new green polishing technique which can be applied in polishing metal workpieces. This processing technique with the characteristics such as polishing no mechanical stresses, high machining efficiency and high uniform polishing quality can polish the workpieces with complex shape. Polishing solution of EPP is salt solution with low concentration (3-6wt%)[1], which is non-pollution and recycling, therefore it can solve the pollution problems brought by electrolytic polishing and chemical polishing[2]. The method can be widely used in polishing, removing burr and oxidation layer, cleaning welding seam and surface stain, and so on. It can play an important role in machinery manufacturing, aviation industry, ship building, chemical industry, food industry, etc.

Mechanism

The workpiece soaked into the polishing solution is linked with DC power positive pole. Meanwhile, polishing solution and polishing cell is linked with negative pole (see Fig.1). At the beginning, because of instantaneous short circuit of the system, a large amount of heat quantity is released so that the solution is evaporated to form a gas layer, which will segregate the workpiece and the polishing solution completely. Discharge channel will be formed in the gas layer under voltage application. The collision between electrons and positive ions moving with high speed in discharge channel produces a large amount of heat energy to the workpiece surface, with heat radiation and gas expansion energy. The involving energy removes the surface melt rapidly. In the convex zone on the undulate surface, the gas layer is thinner, which causes stronger electric field, and electrons with higher speed will reach the surface rapidly, so discharge channel will preferentially form in the convex zone, and material in this location is removed earlier and more.

Experiment

Polishing was performed by using a self-made 40kw EPP machine and ammonium sulfate solution with concentration 0.4% was chose as polishing solution, solution temperature was kept in the range of 79^{o}C-81^{o}C. The material during the polishing was SUS304 stainless steel and was cut into test specimens of 50×20×1.8mm^3. Polishing voltage was 280V. Polishing lasted about 40 minutes. The surface properties before and after polishing were analyzed.

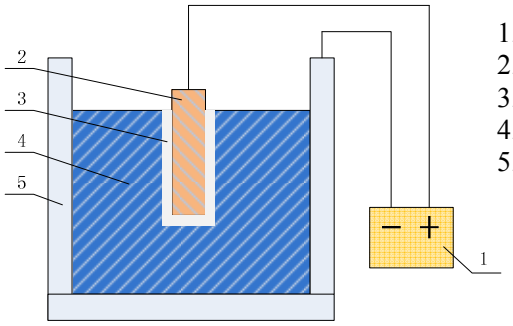

Fig.1. Schematic of EPP

Results and Discussion

Roughness. The initial roughness of the specimens is R_a=0.573μm. Roughness was measured at short intervals during the polishing to obtain the curve of surface roughness with polishing time, as shown in Fig.2. In the first ten minutes, the roughness value decreases quickly from R_a=0.573μm to R_a=0.115μm. While the roughness value decreases to R_a=0.066μm after subsequent 30 minutes, and roughness gradient is small. The larger initial roughness is, the faster roughness decreases. Larger roughness means larger difference of electric field between convex and concave during the polishing, discharge channel forms more easily in the convex places, and more material is removed here, so roughness value decreases faster. Oppositely, difference of electric field is insignificant in flat surface, so the roughness change is small correspondingly.

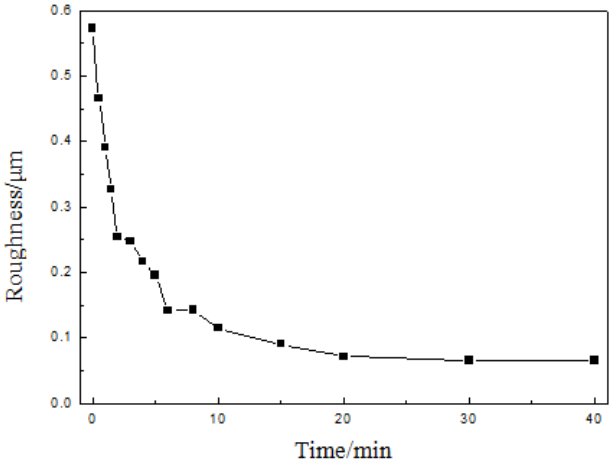

Fig.2 Curve of roughness with polishing time

Micro-morphology. The surface outline of the specimens before and after polishing is measured, as shown in Fig.3. The initial outline curve fluctuates in the range of 5μm. After 10 minutes polishing, sharp location of surface outline is disappeared, the outline curve fluctuates in the range of 1μm and surface is smooth, which is one of the reasons obtaining mirror surface [3]. Fig.4 shows the initial and polished SEM micro-morphology. The specimens are cleaned by acetone before being examined. By looking at the SEM micro-morphology (500x), we can see there are many convexities distributing on the surface of the initial specimen obviously, and after 10 minutes polishing, the convexities are disappeared. Grain boundary is also clear and no corrosion micro-pits on the surface of the polished specimen. The results show the microdefects of the surface can be removed well by EPP.

Surface Chemical Composition. During the polishing, the chemical reactions occur between gas and workpiece, which leads to the change of chemical composition of surface inevitably. The initial and polished chemical composition is analyzed by EDS, as shown in Fig.5. After 10 minutes polishing, the mass percentage and atomic number percentage of Cr increase slightly, but the percentage of other chemical elements almost remains unchanged. This phenomenon depends on

high inertia of Cr, and chemical reaction is preferential to occur between gas layer and low inertia elements such as Fe. The reaction products adhering to the surface are removed by discharge, leading to the relative increase of Cr, which is beneficial for improving corrosion resistance of the stainless steel, as enough Cr in steel is easy formed passivation layer on surface to protect steel from oxidation [4].

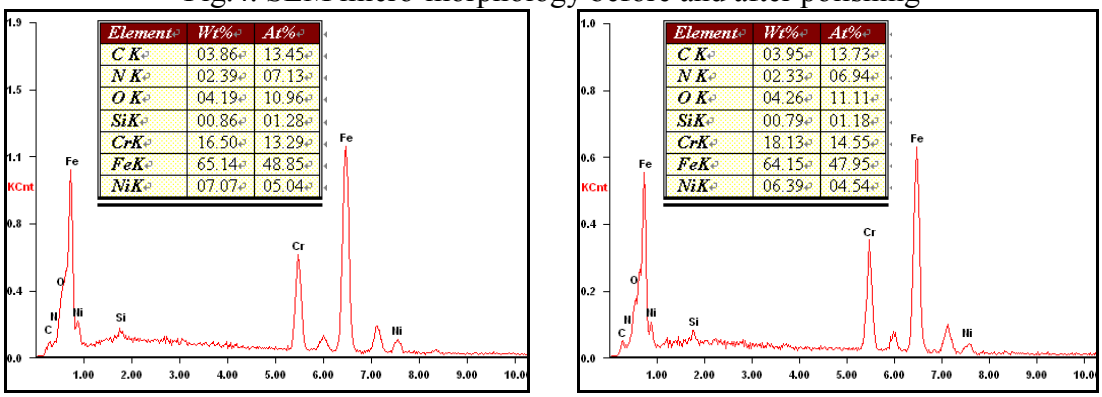
Fig.4. SEM micro-morphology before and after polishing



(a) Initial specimen (b) Polished specimen

Fig.5. Change of chemical composition before and after polishing

Corrosion Resistance. The corrosion resistance of the specimens before and after polishing were measured in NaCl solution with concentration 0.9% by electrochemical analyzer. The scanning speed of the polarization curve was 5mV/s, and the scanning margin is the open-circuit-potential plus or minus 0.25V. The corrosion potential E_{corr} and current density J_{corr} can be obtained through polarization curve in test. The more the E_{corr} offsets towards positive direction, the smaller corrosion tendentiousness is. The smaller corrosion current I_{corr} is, the lower rate of corrosion is [5]. The polarization resistance R_p is given by

$$R_p = \frac{b_a b_c}{2.303(b_a + b_c) J_{corr}} \tag{1}$$

where b_a and b_c are positive Tafel gradient and negative Tafel gradient, respectively.

Fig.6 shows the polarization curves before and after polishing. The polarization curve of the polished specimen offsets towards right obviously. The parameters of b_a, b_c, E_{corr}, I_{corr} can be got by fitting polarization curves before and after polishing, as shown in Table 1. Solving equation (1) with above parameters, polarization resistances R_p are fixed.

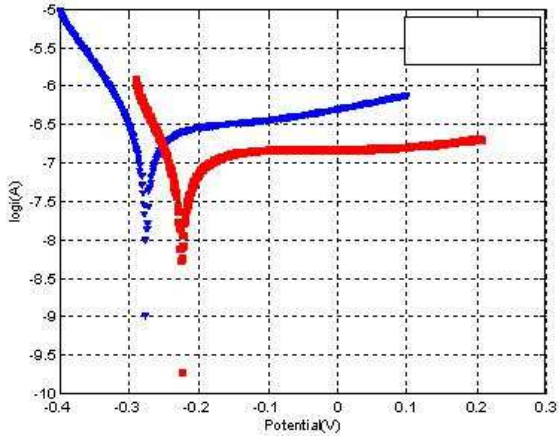


Fig.6 Polarization curves before and after polishing

Table 1. Polarization curve -fitting results before and after polishing

Specimen	E_{corr} (V)	I_{corr} (μA)	b_a	b_c	R_p(Ω)
Inintial	-0.276	2.786e-7	1.337	12.786	110500.4
Polished	-0.224	8.611e-8	1.215	0	247452.0

As observed in Table 1, the corrosion potential of the polished specimen offsets towards positive direction more than the initial specimen's, while the corrosion current is found to be smaller. The results just show the surface corrosion resistance is improved indeed after EPP. On the one hand, the increase of Cr content is beneficial to improve corrosion resistance as discussed above. On the other hand, the surface is smooth after the polishing and microdefects are removed, which prevent corrosion propagation happening on the surface and decrease the corrosion inducements.

Conclusion

SUS304 stainless steel sheets were polished using the new technique of EPP. Surface properties are improved after polishing.

(1) Surface roughness value decreases from R_a =0.573μm to R_a =0.066μm after 40 minutes.
(2) Microdefects on surface are removed well obtaining mirror surface.
(3) The mass percentage and atomic number percentage of Cr increase slightly.
(4) According to electrochemical analyzer, surface corrosion resistance is improved after polishing.

Keywords: Hydroxyapatite; Initial Concentration; Copper Ion; Adsorption;

Abstract: Hydroxyapatite (HAP) is an effective adsorbent for removing heavy metal ions. In this study, HAP was prepared by sol-gel method and used for removing Cu^{2+} from aqueous solution. Initial concentration of Cu^{2+} in the aqueous solution was evaluated as an important parameter determining uptake. The removal efficiency and the adsorption capacity of HAP for Cu^{2+} were investigated. EDS analysis indicated the presence of Cu^{2+} on the HAP surface.

Introduction

Heavy metals pollution is a worldwide environmental problem. The hazardous heavy metals are not biodegradable and tend to accumulate in living organisms, causing various diseases and disorders[1,2]. Therefore, effective strategies for removing heavy metal ions from water and various industrial effluents have attracted considerable research and practical interest[3]. As one of the important toxic heavy metal, copper finds its way to the industrial effluents includes metal cleaning and plating bath, mining, iron and steel production, wood pulp production and fertilizer industry[4,5].

Although previous research has mentioned that HAP had higher efficiency in the removal of heavy metals (Pb^{2+}, Cd^{2+}), little research has investigated the detailed adsorption characteristics of heavy metals removal by HAP[6,7]. Cu^{2+} sorption onto HAP particles has not been studied in detail.

The main aim of this work was to study the efficiency of HAP for Cu^{2+} removal from aqueous solution. Furthermore, we also investigated the influence factor of initial concentration on the removal efficiency of Cu^{2+}.

1. Materials and methods

1.1 Materials

The synthetic HAP was prepared using the standard procedure published in rare metal materials and engineering [8]. The powder was calcined in air at 600°C for 2h. X-ray diffraction (XRD) analysis conformed with the literature and the JCPDS card No. (07-0747). There are no calcium hydroxide and calcium phosphates phase present in the XRD, implying that pure HAP phase was prepared under the present experimental conditions.

The synthetic solution were all prepared by diluting the stock solution (concentration 1000 mg/L) obtained by dissolving $Cu(NO_3)_2$ in deionized water. Before mixing the adsorbent, the pH of each last solution was adjusted to the required value with dilute solutions of 0.1mol/L HNO_3 and 0.1mol/L NH_4OH. All reagents used in this experiment were of analytical grade or better.

1.2 Sorption procedure

Sorption experiments were carried out in batch. The HAP (0.5g) was added into a 100ml metal solutions with the concentration range of 20-200mg/L, was agitated for a specified period of contact time at 600rpm and room temperature. At the end of the adsorption process adsorbent was separated from the solution by centrifuge (TGL-16G). The concentration of Cu^{2+} was measured by atomic

adsorption spectroscopy (AAS, Varian AA220, USA). The copper ions measurements were repeated three times and the results given were the average values. The percentage ions removal by the adsorbent was calculated using the following equation:

$$Y = \frac{C_0 - C_e}{C_0} \times 100\%$$

Where Y is the ions removal, C_0 and C_e are the concentration of metal ions in solution before and after adsorption (mg/L).

The adsorption capacity of HAP was calculated using the general equation:

$$q = \frac{(C_0 - C_e) \times V}{m}$$

Where q is the uptake capacity (mg/g), V is the volume of the solution (ml), m is the amount of the HAP used in the reaction mixture (g).

2. Results and discussion

2.1 Effect of initial concentration of Cu^{2+}

The effect of initial concentration of Cu^{2+} was investigated in the range of 20~200mg/L. the results are presented in Fig.1. The removal efficiency at 240min decreased from 99.64% to 76.68% as Cu^{2+} concentration increased from 20mg/L to 200mg/L. The results indicate that there was a reduction in Cu^{2+} adsorption, owing to the lack of available active points required for the high initial concentration of Cu^{2+}. However, the sorption capacities of the HAP at 240min from increased from 4.18mg/g to 30.17mg/g as Cu^{2+} concentration increased from 20mg/L to 200mg/L (as shown in Fig.2). The reason may be due to increasing the mass transfer driving force.

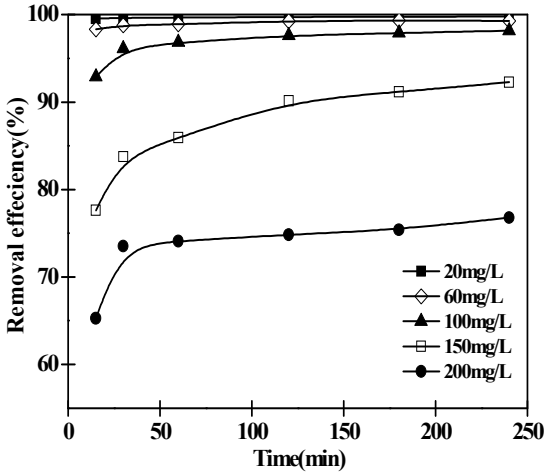

Fig. 1. Effect of initial concentration of Cu^{2+}on the removal efficiency

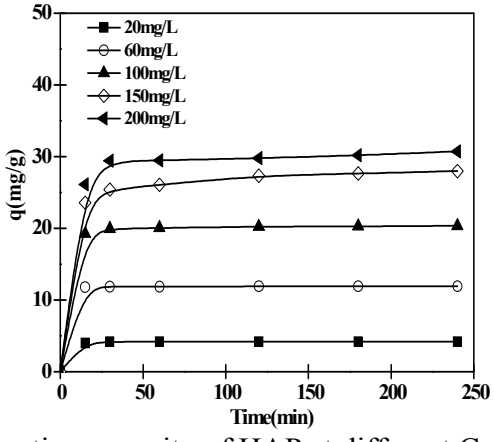

Fig. 2. The adsorption capacity of HAP at different Cu^{2+} concentration

2.2 SEM-EDS analysis

The adsorbent shape and size impact the adsorption capacity of the adsorbent. SEM micrographs of HAP are shown in Fig.3(a). It was observed that the HAP particles are spherical shape with a mean diameter approx. 100nm. This small HAP particles size provides a larger surface area for contaminant adsorption. Fig.3(b) show the micrographs of HAP after the adsorption of Cu^{2+} ions. It can be seen that the HAP became denser and there are some needle-like substance appear. The morphology change of the composite before and after Cu^{2+} treatment indicates the structural changes of the sorbent. The EDS analysis provides direct evidence for the sorption of Cu^{2+} onto the HAP (See Fig.3(c) and (d)).

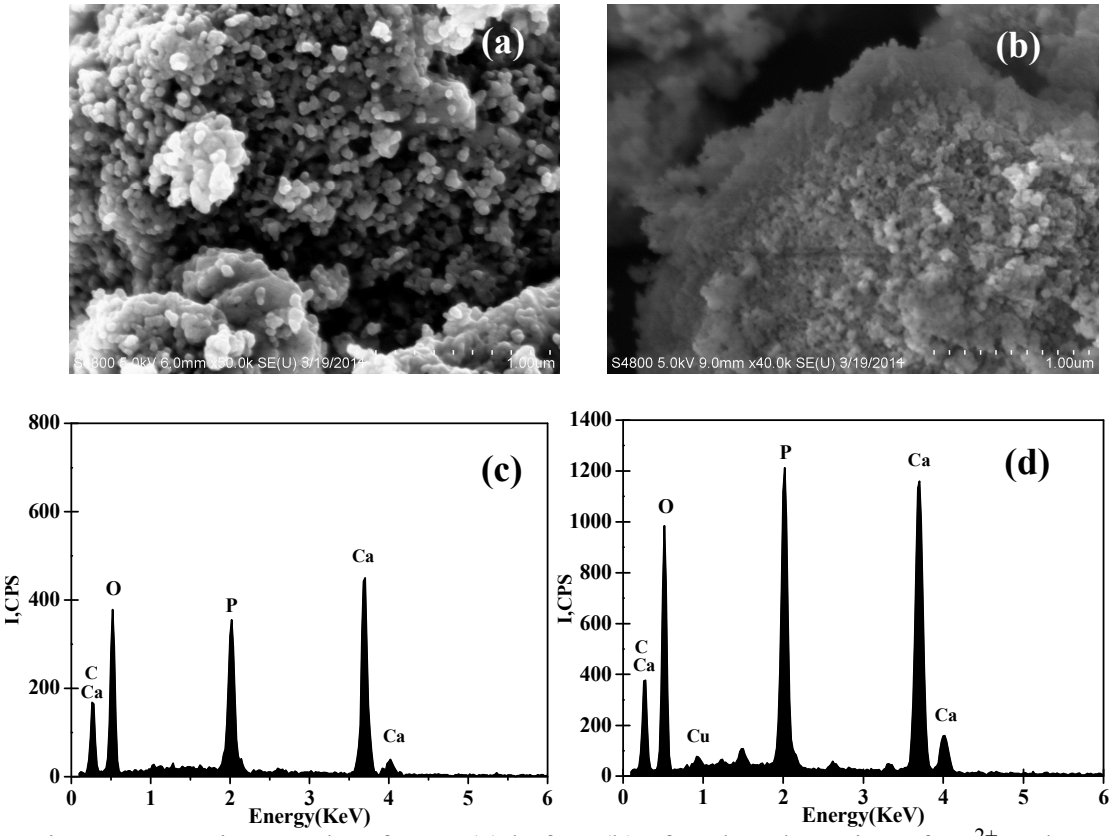

Fig. 3. SEM micrographs of HAP (a) before (b) after the adsorption of Cu^{2+} and EDS analysis of HAP (c) before (d) after the adsorption of Cu^{2+}

3. Conclusions

The present studies clearly reveal that HAP can be used as an effective adsorbent for removing Cu^{2+} from aqueous solution. The sorption performances were affected considerably by the initial concentration of Cu^{2+}. With the increasing of the concentration of Cu^{2+}, the removal efficiency gradually goes down at a specific time. It is speculated that the driving force of adsorption in the process is the concentration gradient. The absorption effect significantly increased due to higher concentration gradient of Cu^{2+}.

KeyWords: Aqueous Lithium batteries; anode material; $Li_{0.95}Na_{0.05}Ti_2(PO_4)_3$/C; Carbon coating

Abstract: $Li_{0.95}Na_{0.05}Ti_2(PO_4)_3$/C nanocomposite was prepared by sol-gel method.The structure and morphology of the samples were characterized by XRD, SEM which showed the particles had typical NASICON structure and diameter range from 400~500nm. The electrochemical performance were tested by cyclic voltammetry and galvanostatic charge–discharge. Results show $Li_{0.95}Na_{0.05}Ti_2(PO_4)_3$/C nanocomposite exhibitsmuch better electrochemical performance than bare $Li_{0.95}Na_{0.05}Ti_2(PO_4)_3$.

1.Introduction

The demand for lithium ion batteries for low cost, high safety and high energy density is more and more urgent. Most of the commercial lithium-ion battery uses the organic electrolyte, which is toxic and flammable. During the large-scale use and high rate discharge situation, the overcharge or short circuit will cause the security problems. Additionally, the high price of organic electrolyte, low ionic conductivity and the strict manufacturing requirements, resulting in high cost of the whole battery. Aqueous lithium ion battery can overcome the shortcomings, save the cost and simplify the process. The NASICON-type $LiTi_2(PO_4)_3$ was proposed as an promising anode material for aqueous lithium ion battery. The theory capacity of $LiTi_2(PO_4)_3$ is 138.3 $mAhg^{-1}$,with stable charge discharge platform. But the electrochemical performance is still not satisfactory because of the capacity fading during cycling[1-3]. In this work, Sodium ion was doped to improve the conductivity and carbon used as conducting additive also acts as a coating prohibiting the dissolution of active mass.

2. Experiment

2.1 Preparation of Li0.95Na0.05Ti2(PO4)3/C

The $LiTi_2(PO_4)_3$/C and Na-doped $Li_{0.95}Na_{0.05}Ti_2(PO_4)_3$/C used as anode active material in this work was prepared by sol–gel method accord-ing to reference[1]. Stoichiometric amounts of tetrabutyl orthotitanate，lithium carbonate，sodium carbonate, and ammonium dihydrogen phosphate were used as starting materials; citric acid was adopted as a chelating agent. The sol was dried 140°C for 12 h, heating at 350°C for 2h and 800°C for 12h. The $Li_{0.95}Na_{0.05}Ti_2(PO_4)_3$ was obtained. Then the powder and glucose milled for 12h ,and heating under the protection of nitrogen atmosphere at 700°Cto get $Li_{0.95}Na_{0.05}Ti_2$ $(PO_4)_3$/C.

2.2. Characterization of the prepared anode materials

Crystal structures of the prepared $Li_{0.95}Na_{0.05}Ti_2(PO_4)_3$/C nanocomposite were characterized by X-ray powder diffraction(XRD) using a Bruker Analytical X-ray System with CuKa radiation source. Scanning electronmicrographs(SEM) were obtained on a Hitachi-S4800 scanning electron microscope.

For electrochemical tests, anodes were prepared by pressing a powdered mixture of the sample, acetylene black, and poly(tetrafluoroethylene) (PTFE) in a weightratio of 80:10:10, stainless steel net as current collector. A two-electrode simulated battery consisting of the $LiMn_2O_4$ cathode and the prepared anode was used to test the electrochemical properties of the materials.Galvanostatic charge and discharge were performed on LAND-CT2001 Charge-discharge Test System in aqueous 5M Li_2NO_3 solution of pH=7. Discharge/charge cut-off voltages were set at 0.3 and 1.6 V.

Cyclic voltammetry was carried out with an electrochemical work station (Zahner-IM6e).A saturated calomel electrode (SCE) and a stainless steel mesh were used as reference and counter electrodes, respectively.

3. Results and discussion

SEM micrographs of $Li_{0.95}Na_{0.05}Ti_2(PO_4)_3$ and $Li_{0.95}Na_{0.05}Ti_2(PO_4)_3$/C nanocomposite are shown in Fig. 1. Evidently, the as-prepared materials with uniform particle size by sol-gel method. The size is about 300~400 nm. And The particle size increased to 400~500 nm after carbon coating.

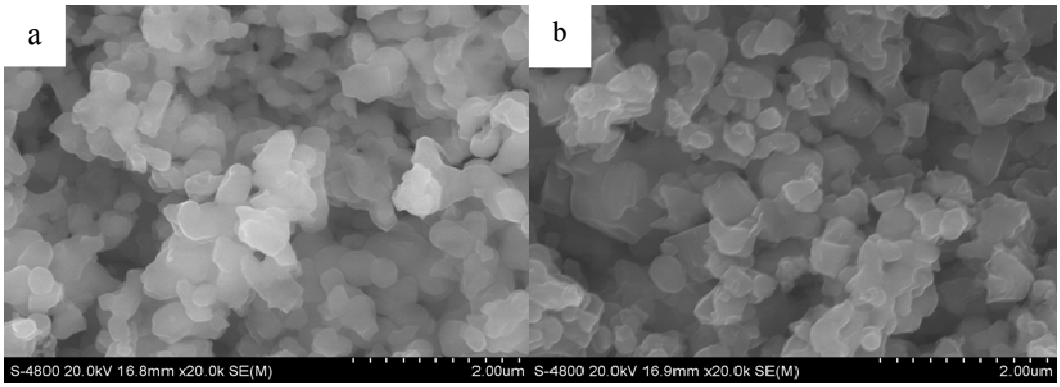

Fig.1 SEM images of $Li_{1-x}Na_xTi_2(PO4)_3$ (a) and $LiTi_2(PO_4)_3$/C(b) samples

The XRD pattern (Fig.2)shows that the characteristic peak positions of both $Li_{0.95}Na_{0.05}Ti_2(PO_4)_3$ and $Li_{0.95}Na_{0.05}Ti_2(PO_4)_3$/C coincide with the standard card. The main peaks are high intensity, narrow half-peak width, which indicated the as-prepared materials described full NASICON structure, polymorph complete development. The diffraction peak intensity of carbon coated materials decreases slightly.

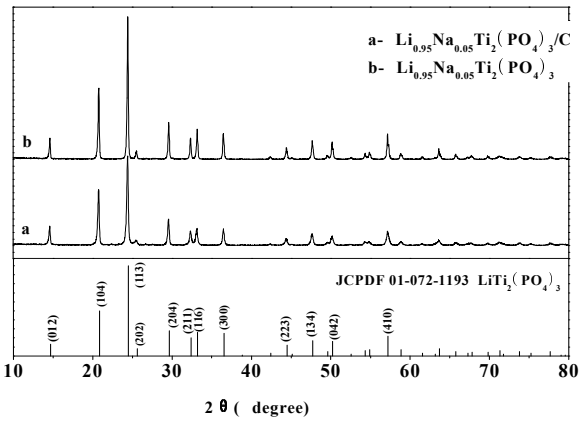

Fig.2 XRD pattern of $Li_{1-x}Na_xTi_2(PO4)_3$/C and $LiTi_2(PO_4)_3$/C samples

Cyclic voltammetry curves of $Li_{0.95}Na_{0.05}Ti_2(PO_4)_3$/C with different scan rates were measured. In order to prevent the hydrogen evolution reaction, scanning potential limitation in -0.8~0.2 V （vs.SCE）,as shown in Fig. 3. Obviously, the nanocomposite present one pair of sharp redox peaks that corresponds to the insertion and extraction of Li ions into and from the $Li_{0.95}Na_{0.05}Ti_2(PO_4)_3$/C structure.With increasing of scanning speed, the shape of peak changed, and the peak current is increased. The oxidation peak and the reduction peak respectively to the positive and negative direction, △U between oxidation potential and reduction potential increases (Figure 3). Shows that the electrode materials have a certain polarization phenomenon. Lithium ions diffusion coefficient in the electrode have great influence on charge discharge performance and battery polarization.

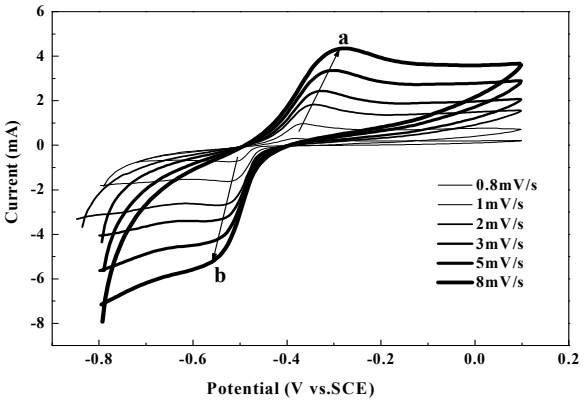

Fig. 3 Cyclic voltammograms of $LiTi_2(PO_4)_3/C$ at different scan rate

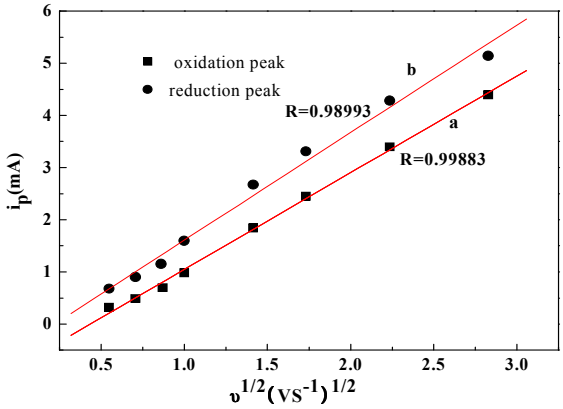

Fig. 4 Relationship of peak current (i_p) vs the square root of scan rate ($\upsilon^{1/2}$)

Relationship between the peak current and the scan rate was shown in Fig. 4. There is a linear relationship between the peak current (i_p) and the square root of the scan rate ($\upsilon^{1/2}$). The diffusion coefficient D_{Li} can be calculated under different peak values. According to Equation: $I_p = (2.69\times10^5)n^{3/2}AC_{Li}^{*}D_{Li}^{1/2}v^{1/2}$

In the experiment A=0.3cm^2，n=2，C_{Li}^{*} is calculated as follows:

$$C^{*}=\frac{n}{V}=\frac{6/6.02\times10^{23}}{1.31\times10^{-27}}=0.761\times10^{4}\ \text{mol/ m}^3$$

According to the Randles Sevcik equation

$$D=\frac{I_P^{\ 2}/v}{2.09^2\times10^{10}\times n^3A^2C^{*2}}$$

The diffusion coefficients of the Li ions were obtained for substitution parameters：4.302×10^{-5}cm^2/s，2.44×10^{-5}cm^2/s，which shows the diffusion coefficients of the oxidation and reduction reaction was basically in the same magnitude. But in the high-speed scanning, the reduction peak of each cycle of the area is larger than the oxidation peak area. The reversibility of material deteriorate in the fast charge-discharge cycle. Dissolution of the electrode material occurs so that the electrolyte becomes yellow, which may be one reason for the fast decay cycle capacity of the material in an aqueous solution. And in the slow scan, the reduction ratio of the peak area of the peaks and the oxidation is nearly equal, indicates that when a small current discharge $Li_{0.95}Na_{0.05}Ti_2(PO_4)_3/C$ material having good reversible deintercalation of lithium.

Fig.5 shows the initial charge-discharge curves of the materials with saturated $LiNO_3$ aqueous solution electrolyte. The initial discharge capacityof $Li_{0.95}Na_{0.05}Ti_2(PO_4)_3$ and $Li_{0.95}Na_{0.05}Ti_2(PO_4)_3/C$ obtained at this condition was 52.9mAh/g,47.6 mAh/g. Fig.6 shows the cyclling performance of $Li_{0.95}Na_{0.05}Ti_2(PO_4)_3$and $Li_{0.95}Na_{0.05}Ti_2(PO_4)_3/C$. The data were obtained at a current density of 0.2mA/cm^2 over the potential range0.3~1.6V.Evdently,discharge capacity of two anode materials were reduced with cycles, but $Li_{0.95}Na_{0.05}Ti_2(PO_4)_3/C$ material capacity fading slowly than $Li_{0.95}Na_{0.05}Ti_2(PO_4)_3$.

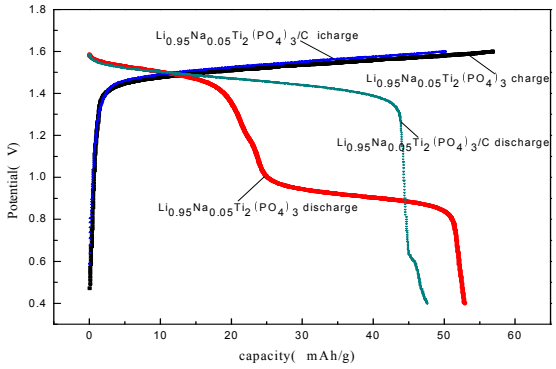

Fig.5 The initial charge-discharge curves of the materials

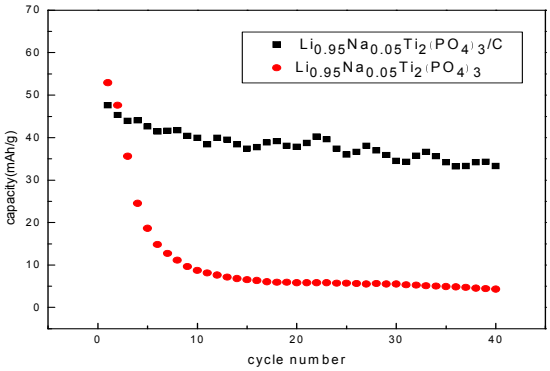

Fig.6 Cycling performance of the materials

The $Li_{0.95}Na_{0.05}Ti_2(PO_4)_3$/C anode materials simulated battery initial discharge capacity of 47.6 mAh/g, after 40 cycles, the discharge capacity of 33.3 mAh • g-1, the capacity retention rate of 70%. Although $Li_{0.95}Na_{0.05}Ti_2(PO_4)_3$ shows hihger capacity of 52.9mAh/g, 4.3 mAh/gremained after 40 cycles, the capacity retention rate of 8%.The possibility of the decomposition of water and the dissolution of $Li_{0.95}Na_{0.05}Ti_2(PO_4)_3$ lead to the capacity fading.

4.Conclusion:

$Li_{0.95}Na_{0.05}Ti_2(PO_4)_3$ prepared by sol-gel method shows completely NASICON structure , the size is about 300~400 nm, the carbon coated particle $Li_{0.95}Na_{0.05}Ti_2(PO_4)_3$/C size increased to 400~500 nm. By comparing the results of CV test, $Li_{0.95}Na_{0.05}Ti_2(PO_4)_3$/C material has good lithium reversible, but in the rapid scanning, Li^+ can not diffuse to the electrode surface, the polarization increases, which may be one of the reasons for capacity fading. Capacity of $Li_{0.95}Na_{0.05}Ti_2(PO_4)_3$/C the first discharge capacity of 47.6 mAh/g after 40 cycles, the discharge specific capacity is 33.3 mAh • g-1, the capacity retention was 70%.

Keywords: melting temperature; in-situ; TiC/Al composite; Al_4C_3; Al_3Ti

Abstract. Formation mechanism of TiC in Al matrix at a rather low melting temperature using in situ technology was studied. And effect of the melting temperature on the microstructure of in-situ TiC/Al composite was investigated. The results indicate that, the resultants of TiC and Al_3Ti were found out in the matrix; however, no evidence showed that Al_4C_3, a resultant phase existed probably in TiC/Al composite in accordance with the relative reference, was found out. Compared to the sample of T750, more TiC and less Al_3Ti existed in the sample of T850, and morphography of Al_3Ti changed from block to bar with the increasing melting temperature. The melting temperature affected extremely the reaction speed and the resultants.

Introduction

TiC/Al composite prepared with in situ method has been studied for decades and presents broad applications including in automobile, aerospace and military industries due to its remarkable specific strength, stiffness and modulus [1, 2]. However there is no agreement on mechanism of in situ synthesis of TiC reacted in aluminum melt, though it has been investigated for many years [3]. Kun jiang[4] and M. K. premkumar[5] consider that TiC is formed from the reactants of dissolved carbon and titanium; but some studies[6, 7] support that resultant of TiC derives from the reaction of Al_3Ti and Al_4C_3; meanwhile, some researches[8, 9] think the mechanisms mentioned above exist together. Therefore, there is not an unified theory to explain the formation of TiC in TiC/Al composite.

Brittle Al_3Ti is considered as a harmful phase in the TiC/Al composite because it results severely in low properties of both strength and ductility. According to the reference[10], a proper approach to decrease the amount of Al_3Ti is to increase melting temperature of the TiC/Al composite. When the molting temperature was over 1000℃, Al_3Ti was effectively reduced, and the size of the resultant of TiC was 2-3μm[11]. The brittle phase of Al_3Ti disappeared when the melting temperature was above 1200℃[12]. However, two disadvantages are inevitable using this conventional method: waste of energy and rapid growth of TiC grains at a high melting temperature [13].

This paper presents a fabricating process of TiC/Al composite using in situ technique. The conventional Al-Ti-C mixed powder was used as the reaction system. A special device was designed to introduce the green contacts into the molten. The aim of our research is to discuss the mechanism of the formation of TiC in the system of Al-Ti-C by means of analysis of the change of the microstructure of the composites fabricated at different melting temperature, and effect of the melting temperature on the microstructure of TiC/Al composite was discussed. Two different melting temperatures of 750℃ and 850℃ were considered.

Experimental procedure

Commercial pure aluminum was used as the matrix, titanium powder (99.5% pure, 325 mesh), aluminum powder (99.5% pure, 200 mesh), graphite powder (99% pure, 200 mesh) were considered

as additives for the in situ reaction system. A mixture of powders was pressed into a cylindrical contact with a diameter of 10mm and a height of 10mm at 20MPa, in which the molar ratio of Ti:C was 1:1.2 and the content of aluminum powder was 30wt.%.

A pure aluminum ingot was first molten in a graphite crucible in the furnace, and then the contacts were put into the liquid Alumina. The schematic of the fabricating equipments was shown in Fig.1. After 15min, a stainless steel stirrer was used to improve the uniformity of the melting composite. The melt was held for 10min to release the gas and slag, then the melt was cast into a steel mold preheated to 200℃. The composite samples prepared at 750℃ and 850℃ were designated as T750 and T850, respectively.

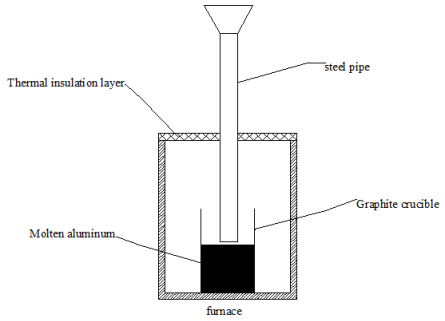

Fig.1Schematic diagrams of fabricating device for in situ TiC/Al composites

The microstructure was investigated by means of the optical microscope (OM), the scanning electron microscope (SEM) equipped with energy dispersive spectroscope (EDS). Phase analysis was performed using X-ray diffraction (scan rate was 0.02^{o}/s).

Results and discussion

In the process, the contacts were rapidly dropped into the liquid Alumina and the in situ reaction took place inside the liquid, and no visible spark appeared.

The XRD pattern (Fig.2) shows that there are four phases in the product of T750 and T850, i.e. Al, Al_3Ti, TiC and C , The emergence of graphite in the sample of T750 and T850 indicates that the reactions has not took place completely, but it worth noting that the amount of graphite is very little in T850. The diffraction peak of Al_3Ti in the T850 is weaker than that in the sample of T750, indicate that the amount of Al_3Ti in the product of T850 is lower.

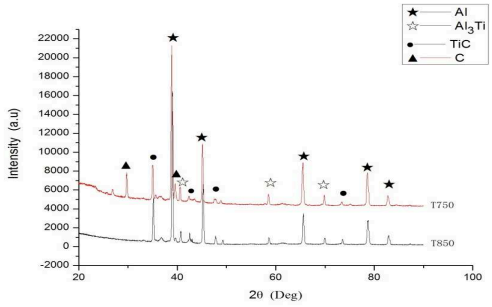

Fig. 2 XRD patterns of the sample T750 and T850

Fig.3 (a) shows the micrograph of sample T850. The grain boundary is clearly delineated by some tiny second phases, it was considered that these tiny particles were pushed by grain boundaries during solidification, Rod-like Al_3Ti was also founded in sample T850 (Fig.4). Combining XRD patterns in Fig. 2 and EDS results in Fig. 5, these tiny particles distributing at the grain boundary were confirmed as the compound of Al_3Ti and TiC.

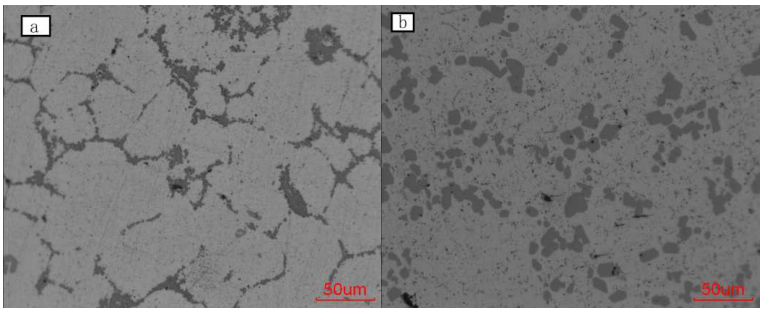

Fig.3 (a) OM micrograph of T850; (b) OM micrograph of T750

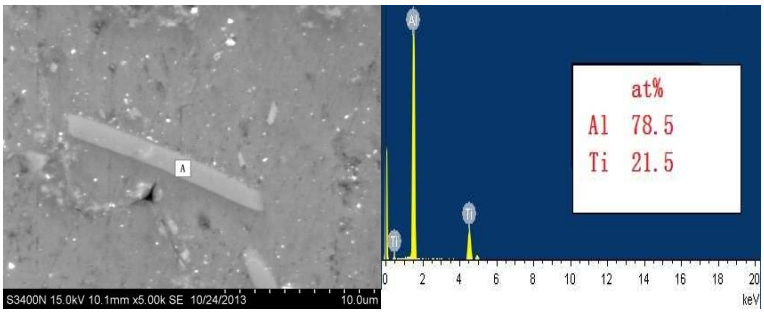

Fig.4 SEM photographs of the rod phase in T850, the composition of A was listed in right table

Fig.3 (b) shows the OM micrograph of T750. It was found that there were many block-like Al_3Ti in the matrix as well as some graphite phase. The interface and the map scanning distribution of elements of the dark zones in sample T750 was shown in Fig.6, Graphite phase was surrounded by a layer which was rich in titanium. It was confirmed as the mixture of Al_3Ti and TiC.

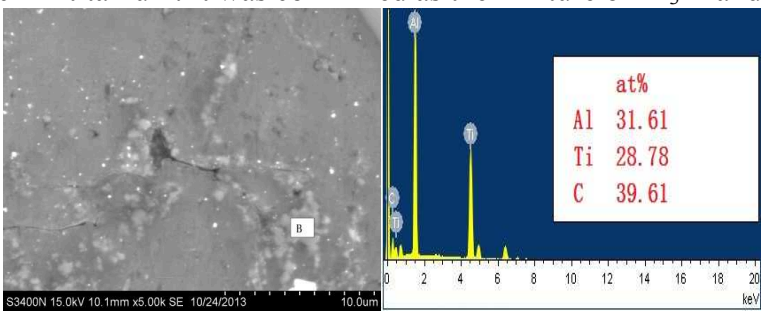

Fig.5 SEM photograph of the phase assemble at the boundary, EDS results of point (B) is listed on the left photograph.

The TiC/Al composite system has been investigated by many researchers, but the mechanism of the reactions is still unknown. Some reactions may take place as the follows equations:

$$Ti(s) + C(s) \rightarrow TiC(s) \quad (1)$$

$$Al(l) + Ti(s) \rightarrow Al_3Ti(s) \quad (2)$$

$$Al(l) + C(s) \rightarrow Al_4C_3(s) \quad (3)$$

$$Al_4C_3(s) + Ti(s) \rightarrow Al(l) + TiC(s) \quad (4)$$

$$Al_3Ti(s) + Al_4C_3(s) \rightarrow Al(l) + TiC(s) \quad (5)$$

$$Al_3Ti(s) + C(s) \rightarrow Al(l) + TiC(s) \quad (6)$$

Reaction (1) would not happen if the temperature under 1873K. In the early stage of the reaction, the temperature was low, the condition of the Thermodynamic was not enough, this reaction is not the main source of the TiC. The Gibbs free energy of reaction (2) is negative. Moreover, it is known that the reaction (2) occurs between 890~990K, and this reaction will release huge energy, the vast heat coming from the reaction (2) would accelerate the formation of TiC, there is no evidence (4) , (5) and (6) which reaction is the source of TiC. For reaction (4), firstly, whether the reaction (4) occur or not depend on the reaction (3), secondly, it is known that at the beginning of the reaction, almost all of the titanium is consumed by the reaction (2). So there is almost no Ti was left for the

reaction (4), the XRD pattern (Fig.2) and EDS indicate that there is no Al_4C_3 exist in the composites, in spite of some articles [14, 15] reported that Al_4C_3 was found in the product of TiC/Al composite. This phenomenon may have three assumptions:

1. The amount of Al_4C_3 is too little to be found.
2. The produced Al_4C_3 has been consumed by other reactions.
3. Al_4C_3 has not been produced.

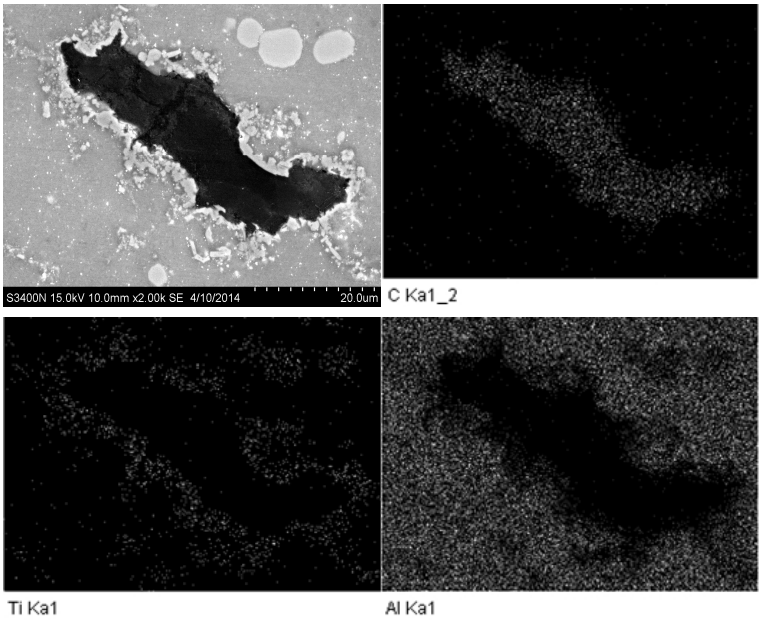

Fig.6 The interface and the map scanning distribution of elements of the black area in T750

There is no sign of Al_4C_3 neither in EDS nor in XRD pattern, so the first assumption is too farfetched; As for the second assumption, for the sample of T750, the melt temperature was only 750℃, and the mojority of the second phases is Al_3Ti, so it is highly unlikely that the reaction completed totally, and this assumption can be denied according to the direct proportional relationship of Al_3Ti and C in T750 and T850. The third assumption is the best answer for the absent of Al_4C_3. In that case, Reaction (6) is the source of TiC. This conclusion can be explained by the information of Fig.6. It is very clear that graphite is surrounded by Al_3Ti and TiC, it seems that the reaction has not totally complete before solidification. Meanwhile, the amount of TiC has increased along with the decrease of Al_3Ti. This fact is confirmed by the XRD pattern (Fig.2) analysis.

The reactions take place once the contacts were introduced into the aluminum melt. Al_3Ti was formed firstly from the reaction between aluminum and titanium, with the help of the huge energy released from the reaction (2), reaction (3) occurs, due to the low melt temperature, the speed of the reaction (2) is slower in T750 than T850, and the ultimate temperature of T750 is lower than T850, the reaction (3) is more completely in T850 , so there is more TiC and little Al_3Ti in T850; the consume of Al_3Ti result in the decrease of the amount of Al_3Ti and the change in morphography of Al_3Ti, this is confirmed by the phenomenon of tiny Al_3Ti and TiC was assembled around the graphite while other Al_3Ti was bigger in size which was far away from the graphite (Fig.6).

Conclusions

TiC/Al composites were successfully fabricated using in situ method, formation mechanism of TiC was investigated, and effect of the melt temperature on the microstructure of the composite was also discussed. The results indicate that two step of the reaction for the formation of TiC are inevitable in low melt temperature, i.e., Al_3Ti was firstly formed, then the reaction between Al_3Ti and graphite occur, this reaction is the source of TiC. When the melt temperature was 750℃, there are a lot of unreacted block-like Al_3Ti in the composite, when the temperature was increased to 850℃, the amount of Al_3Ti decreased and its shape changed into bar-like. In addition, in the whole

process, the resultants of TiC and Al_3Ti were found out in the matrix; no Al_4C_3 phase was found out, which means the study is opposite to some reference. Compared to the sample of T750, more TiC and less Al_3Ti existed in the sample of T850, and morphography of Al_3Ti changed from block to bar with the increasing melting temperature. The melting temperature affected extremely the reaction speed and the resultants.

Key words: Al-3.2Mg alloys; microstructure; alloy element; tensile property

Abstract: Effect of Cr element on microstructure of Al-3.2Mg alloys was investigated using optical microscopy, scanning electron microscopy (SEM) and EDS. Moreover, the tensile and hardness test were carried out. The results show that a minor additive of Cr can refine effectively the secondary dendrite arm spacing and decrease the number of coarse interdendritic structures. In the whole series of the alloys, the secondary dendrite arm spacing of Al–3.2Mg-0.1Cr alloy was the smallest, and the spacing presented an increasing trend with the Cr content. With high levels of Cr, the intermetallic compounds are formed by Cr with Al, Mg and Fe, the shape of the second phase particles were transformed from bulky bone shape to fine bone shape and long striped. The strength and the hardness of Al–3.2Mg alloys were greatly improved when the additions of Cr were 0.05% and 0.1%, but the ductility of the alloys remained at a low level by adding 0.05%Cr. Therefore, combining with the comprehensive properties and the microstructure, the best addition of Cr in the alloy was 0.10% in the whole series.

1. Introduction

Al-Mg series alloys are very important light-weight structure materials among advanced engineering materials, attracting more and more interest due to their remarkable mechanical properties. The alloys have been widely used in aerospace industries, transportation, ship structure, wire and cable fields with respect to their advantages, such as favorable strength, high ductility, low density, good workability and good corrosion resistance, etc [1–3].

Al-Mg series alloys have been widely studied for a long time, Al-3.2Mg alloy belongs to the alloy that can not be strengthened by heat treatment. In general, in order to broaden the application of Al–Mg series alloys, mechanical properties need to be further improved. Currently, micro-alloying and pre-strain have been used to improve the mechanical properties of Al–Mg series alloys. Mg is the main alloying element, the favorable strength of Al-Mg alloy derives from the solid-solution strengthening of magnesium [4]. Other alloying elements such as chromium and zirconium are also very important in strengthening. One approach toward improving the strength of Al-Mg alloys is to add small quantities of Cr. Cr is the common alloying elements in Al-Mg and Al-Mg-Si alloy, because it can improve and enhance the mechanical properties of the alloy [5-7]. While several researchers have indicated that Cr element can increase the strength of Al-Mg alloys, but the relationship between Cr content and the mechanical properties of Al-3.2Mg alloy have not been systematically reported. So this study was attempted to find the optimal formula of alloy content and investigate the effects of Cr on the microstructure and mechanical properties systematically.

2. Experimental

A series of Al-3.2Mg alloys were produced by pure Al, pure Mg and Al-10%Cr master alloy. The normal compositions of the studied alloys are listed in Table 1. The alloys were melted in graphite crucible in an electric resistance furnace, the melting temperature of the alloy was kept at 780 °C and casting was kept at 710 °C. After the process of C_2Cl_6 addition, the alloy melt was held

for 5 min and then cast into an iron mold. The specimens of metallographic analysis were cut from the center of the ingot. Cylindrical tensile specimens were machined from the as-casting specimens.

The Olympus optical microscope (OM, OLYMPUS BX51M, Japan) was used to observe the metallurgical microstructure of the specimens. The micrographs of fractures were observed by scanning electronic microscope (SEM, HITACHI-3400N, Japan) in order to evaluate the fracture mechanisms. Microstructure examination and composition analysis were carried out using scanning electron microscope (SEM, HITACHI-3400N,Japan) coupled with energy-dispersive spectrometry (EDS, Horiba-EX250, Japan).Tensile tests using a tensile test machine (INSTRON-3367, USA) at room temperature. Hardness was determined in HBE-3000A brinell hardness machine.

2	3.2	0.05	Bal
3	3.2	0.10	Bal
4	3.2	0.15	Bal
5	3.2	0.20	Bal
6	3.2	0.25	Bal
7	3.2	0.30	Bal

3. Results and discussion

3.1 As-cast microstructures

Fig.1 shows the optical microstructure of the as-cast Al-3.2Mg (-Cr) alloy. As shown in Fig.1(a), dendritic structures can be observed clearly in No.1 alloy, the coarse dendrite was found in cast structure of the Al-3.2Mg alloy. As shown in Fig.1 (b)-(g), it can be seen that the microstructure of the alloys was still the dendritic structures, but the coarse dendritic structure became less. The nano particle size of the measurer analysis software was used to measure the secondary dendrite arm spacing of alloy. As shown in Table 2, the secondary dendrite arm spacing of the as-cast Al-3.2Mg-(Cr) was decreased. Table2 shows that the increase of Cr element from 0.05% to 0.1% can reduce the secondary dendrite arm spacing markedly. However, increasing the percentage of Cr element from 0.15% to 0.3% makes the secondary dendrite arm spacing showing a trend of coarsening. The secondary dendrite arm spacing of No.1 alloy was the largest, and the average size of No.1 alloy was about 17.269 μm. The secondary dendrite arm spacing of No.3 alloy was the smallest, the average size of which was about 14.583 μm. The results show that a minor additive of Cr can refine the secondary dendrite arm spacing effectively and decrease the number of coarse interdendritic structures.

The process of alloy solidification is usually conducted from surface to the center, and the final morphology of grain depends on the front liquid condition of the interface of solidification [8-10]. Dendrites usually appear in the large and wide area of constituent supercooling [11]. Cr element is known to have greater affinity with aluminum. Thus Cr element enters the groups of atoms formed by melt structure and melt energy easily. The structure of the atoms cluster containing Cr is proved to be more stable. What's more, the atoms cluster is easier to grow up to be the basement of the nucleation. Therefore, Cr element can refine the growth of the as-cast grain effectively to some extent. But excessive amount of Cr element would greatly increase the degree of supersaturation of solid solution. It will lower the constituent supercooling of the solidification front in the liquid phase, which will lead the embryos of solidification interface to continue growing in liquid phase. In this way, the bulky dendrite will finally appear in the ingot casting organization [11-14]. At the same time, excess Cr can also form bulky intermetallic compounds. When the bulky intermetallic compounds become nucleation particles, the as-cast organization will coarsen. It is the reason that

increasing Cr from 0.15% to 0.3% makes the secondary dendrite arm spacing showing a trend of coarsening.

Size(μm)	17.269	15.349	14.583	15.762	15.442	16.320	16.745

Fig.2 shows the high magnification optical microstructure of as-cast Al-3.2Mg (-Cr) alloy. As shown in Fig.2, the intermetallic compound formed at the grain boundaries as well as around the dendrites. SEM image of as-cast microstructure is shown in Fig.3. Combining with Fig.2 as well as Fig.3, it can be seen that the bone shape second phase particles are found. With high levels of Cr, the shape of the second phase particles were transformed from bulky bone shape to fine bone shape and long striped. But in excess of Cr can also form a small amount of bulky intermetallic compounds. The results of each EDS analyze of the four alloy show that the main elements of the intermetallic compounds are Al, Mg, Fe in No.1, No.2 alloy. And the main elements of the intermetallic compounds are Al, Mg, Cr, Fe in No.7 alloy. It can be deduced that the intermetallic compounds are formed by Cr with Al, Mg and Fe.

3.2 Mechanical properties

Tensile and hardness tests were performed to acquire the effect of Cr on mechanical properties of the cast aluminum alloy. Fig.4 shows the mechanical properties of the as-cast alloys. Both brinell hardness and tensile strength increased with addition of Cr, but the elongation was somewhat decreased. When Cr element content was 0.05% and 0.1%, the brinell hardness and the tensile strength both increased greatly, but elongation was greatly reduced by adding 0.05%Cr. Comprehensive consideration, the best content of Cr to the mechanical properties was 0.10%. The ultimate tensile strength and the tensile strain of the Al-3.2Mg-0.1Cr alloy were 197.7MPa and 37.4%. Compared with Al-3.2Mg alloy (185.5MPa and 39.2%), the tensile strength was increased by 6.6% and the tensile strain was decreased 4.8%.

Combined with optical microstructure and EDS spectrum of particle, the dendrites were refined with the addition of Cr in some degree. With the increase of Cr content, the secondary dendrite arm spacing increased first and then decreased. When the content of Cr element was 0.1%, the secondary dendrite arm spacing was the smallest, and the tensile strength was the largest. With the increase of the secondary dendrite arm spacing, the tensile strength showed a trend of falling. But when the Cr element added too much, the dendrites were coarsen and the coarse grain had more

dislocation pile-up than fine grain, therefore, it was easy to produce larger stress concentration and generate crack initiation, which lead to the decrease of the ductility [15-17].

Part of Cr element can functioned as solution strengthening elements. With the increase of Cr content, the intermetallic compounds are formed by Cr with Al, Mg and Fe. The shape of the second phase particles are transformed from bulky bone shape to fine bone shape and long striped. The fine bone shape and long striped intermetallic compound and the dendrites play a role as barriers to the transmission of the dislocations and hinder the crack propagating [18].

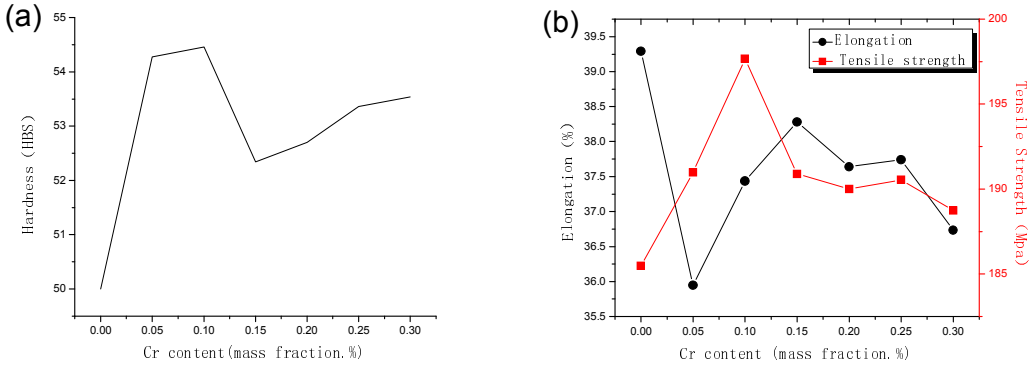

Figure.4 Mechanical properties of studied alloys: (a) Brinell hardness of alloys at different Cr content; (b) Tensile properties of alloys at different Cr content

4. Conclusions

（1）The secondary dendrite arm spacing of the as-cast alloy will decrease with adding a small amount of Cr content. But excessive amounts of Cr element would greatly increase the degree of supersaturation of solid solution, In this way, the bulky dendrite will finally appear in the ingot casting organization.

（2）With increasing Cr content, the shape and size of the second phase are transformed from bulky bone shape to fine bone shape and long striped. But at the same time, excess Cr can also form bulky intermetallic compounds.

（3）Brinell hardness and tensile strength increased with addition of Cr, and the elongation was somewhat decreased. Comprehensive consideration, the best content of Cr was 0.10%.

Keywords: Melting-Casting; Al_2O_3-metal coating; Microstructure; Element distribution.

Abstract: A sort of Aluminum-metal coating, which is characterized by a bi-layered structure of Fe_2O_3+Cr_2O_3+Al plus NiO+Al layers, was successfully prepared on steel substrate by melting-casting technique. The microstructure, the bonding status of the interface between the coating and the substrate, and the element distribution of the coating were studied. The results indicate that, there is an excellent bonding between the coating and the substrate, and no hole and gap in the composite is found out. Moreover, there is obvious element diffusion in the interface. The coating is composed of block phase, columnar grain, and dendrites. In addition, the elements present a uniform distribution in the interface but an obvious segregation in the middle of the coating.

1. Introduction

In modern industry, many metal components of machinery are often surrounded by some harmful media such as corroded gas, water or chemical medium. They are also suffered from severe wear due to their relative motion. The surface failure is easily caused by the mentioned factors. Correspondingly, low working life or high maintenance cost becomes inevitable [1].

The cermets coating has exhibited excellent properties on resistances against wear and corrosion. Therefore, preparation of cermets coatings on the components is an effective method to reduce wear and corrosion [2]. A number of coating techniques like atmospheric plasma spray [3-4], High Velocity Oxy-fuel [5-6], laser cladding [7], plasma cladding [8], vapour deposition [9-10], and so on, have been investigated to produce cermets coating used in abrasive and erosive wear.

Self-propagating high-temperature synthesis (SHS) is an advanced technology to produce ceramics, cermets and intermetallic materials. Materials prepared by SHS are reported to be purer and require less energy than conventional methods, which are generally energy and time-intensive processes [11-13]. Researchers have tried to obtain ceramic, cermets and intermetallic coatings on metal substrates by SHS. This is a novel coating technology, which combines the fabrication of a material with its coating process. Thick coatings could be produced by it, too [14].

This study was attempted to prepare Al_2O_3 ceramic-metal coating on steel substrate with SHS process at a static condition, which meant that no complicated equipment and strict working conditions were necessary. The morphology, combining condition of interface between the Al_2O_3-metal coating and substrate were investigated in detail, as well as organizations and the distribution of elements in the coating.

2. Experimental method

2.1 Coating preparation

The characteristics of the experimental raw materials are shown in Tab. 1

Table 1 The characteristics of experimental raw materials

Raw material	Fe_2O_3	Cr_2O_3	Al	NiO
Purity（wt.%）	99.0	99.0	99.0	99.0
Particle size（μm）	0.2-0.8	0.5-2.0	4-70	0.3

The ingredient of the SHS system was based on the chemical reaction equations (1)-(3) and a little more Al powders were added to ensure the reaction completely. So the molar ratio of Fe_2O_3: Cr_2O_3: Al was 6:4:21, and the molar ratio of NiO: Al was 3:2. The powders were mixed for 6 hours in a ball-mixed mill. Carbon steel Q235 was used as the substrate with dimension of 50mm×40mm ×6mm and it was sandblasted and cleaned before coating.

$$Fe_2O_3 + 2Al \rightarrow Al_2O_3 + 2Fe \quad (1)$$

$$Cr_2O_3 + 2Al \rightarrow Al_2O_3 + 2Cr \quad (2)$$

$$3NiO + 2Al \rightarrow Al_2O_3 + 3Ni \quad (3)$$

The transition layer and working layer powders were mixed evenly with alcohol respectively, forming a paste. Put the obtained paste transition layer on the pre-treatment steel substrate surface with a thickness of about 5 mm. Bake them in an oven at 100 ℃ for two hours; Put the working layer paste on the above of transition layer with thickness of approximately 22 mm. Then bake them at 100 ℃ for six hours. Then the coated sample was placed in a resistance furnace heated to 500 ℃. Trigger the synthesis reaction system by igniting the magnesium ribbon.

2.2 Analysis and test equipment

The surface morphology and microstructure of the coating, the interface of the coating and substrate were observed by means of Hirox KH-7700 Digital Microscope, Olympus BX51M microscope (OM) and Hitachi S-3400N Scanning electron microscopy (SEM) respectively. The distribution of chemical elements was ascertained with Horiba EX-250 energy dispersive spectrometer (EDS).

3. Results and Discussion

3.1 Morphology of the interfacial region

Fig. 1 shows the interface figure of coating-substrate region after etching. It was clear to find three regions in fig. 1, labeled A, B, C, respectively. The A, B, C regions were analyzed by energy dispersive spectrometer, and the results were shown in Table 2. Point A was mainly composed of Al and O elements. Some Fe, Cr, Ni elements also dissolved in point A. It could be inferred that zone A was Al_2O_3-metal coating. Point B was mainly composed of Fe (53.3 wt. %), Ni and Cr, as well as a small amount of Al and O elements. It could be inferred that area B was the steel substrate, which penetrated a lot of Ni and Cr elements. Therefore, the region B was called the diffusion layer. Point C was mainly composed of Fe (89.52 wt. %), as well as a small amount of Ni, Cr, Al, and O elements. Thus it can be inferred that area C was steel substrate.

Therefore, the area from left to right is steel substrate, diffusion layer and coating, respectively. As can be seen from Fig. 1, the coating combined the substrate well at the interface. Neither cracks nor large pores appeared and the bonding interface was jagged. One of the reasons may be that the surface of steel substrate was uneven itself. The other reason was that micro-melting of a partial substrate occurred. This could be further seen from the data in Table 2. Large numbers of elements spread between A and B region.

Since the reaction system released tremendous heat, which not only made the final product completely in the molten state, but also made steel substrate surface in micro-melting state. At high temperature, Ni and Cr elements were easily to diffuse from coating to the steel substrate, forming the diffusion layer. Further, since the poor wettability of metal and ceramic, metal and ceramic phase separation occurred during solidification process. So the formation of aggregates of metal particles present in the coating.

Table 2 EDS results of points A B C in Fig. 2

Elements	A		B		C	
	mass%	at%	mass%	at%	mass%	at%
Al	41.77	41.61	1.94	3.84	2.33	4.56
Fe	8.96	4.32	53.30	50.94	89.52	84.73
Cr	8.56	4.43	15.28	15.67	3.23	3.28
O	25.35	42.61	1.14	3.81	1.25	4.13
Ni	15.36	7.03	28.34	25.74	3.67	3.30

3.2 Microstructure of the coating

Fig. 2 shows the photograph of coating near the interface. From the figure, it can be seen that the coating was relatively dense with almost no pores. The coating had a fine and homogeneous microstructure, only a few metal particles presented in the coating. With increasing distance from the interface of the coating, pores and coarse microstructure began to appear.

Fig. 3 is the SEM of the central coating. It can be seen that the microstructure as a whole showed a certain direction, growing along the direction perpendicular to the interface [15]. However, when growing to a certain extent, the microstructure began to grow in all directions without any regularity. Fig. 4 shows the further amplified columnar grain area. Columnar grains were paralleled to grow in the same direction with uniform thickness. The average thickness of the evenly columnar grain was about 1.5-2 μm. The dendrite arm spacing was about 2.0 ~ 2.5 μm. Another area of the columnar crystals was further amplified in Fig. 5. There were some dendrites appearing in the top of columnar crystals.

Crystallization of the alumina ceramic is also a process of nucleation and growth, just like metal crystallization. The solidification of SHS product is typically a non-equilibrium process [16]. The melting product of complete reaction nucleates firstly on the carbon steel substrate in low temperature. Because of a large undercooling and numerous of nucleation, the nucleus grow rapidly and touch each other. What's more, the timely feeding of products in molten state can get the final products more compact. Thus the small and dense solidification structure without directions is formed. The grain grows along the reverse heat flux extending across the liquid to form columnar crystals. Initially, each dendrite grows in different directions from each other. Only those dendrites growing parallel to the direction of heat flow can be extended forward. The dendrites in unfavorable orientation are not conducive to grow and would be gradually phased out. In this way, the columnar grain structure is gradually formed. Since it is a non-equilibrium process in a rapid cooling speed, and there is still a violent reaction. These factors would disorder the heat flow direction which leads to the columnar crystal growth not in an entirely perpendicular direction to the steel substrate. Since the release of latent heat to the liquid phase during solidification, the liquid in the direction perpendicular to the crystal axis has a negative temperature gradient. Then the crystal axis would appear secondary crystal axis. Similarly, the second crystal axis would grow third crystal axes.

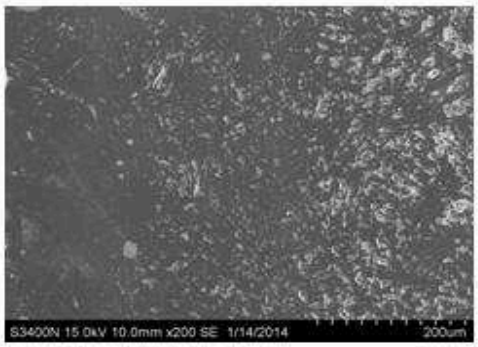

Fig. 2 SEM photograph of coating interface

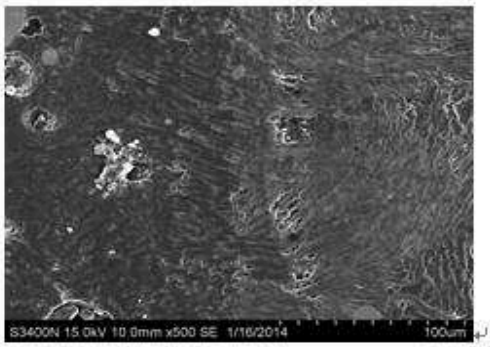

Fig. 3 SEM photograph of the central near the coating

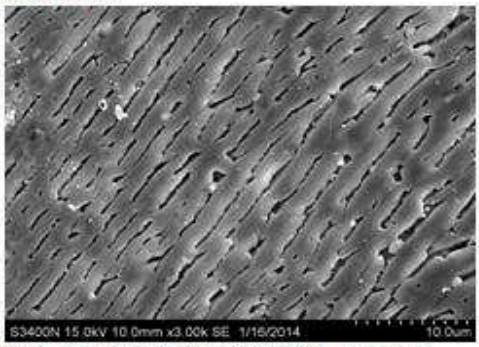

Fig. 4 SEM photograph of the amplified columnar grain

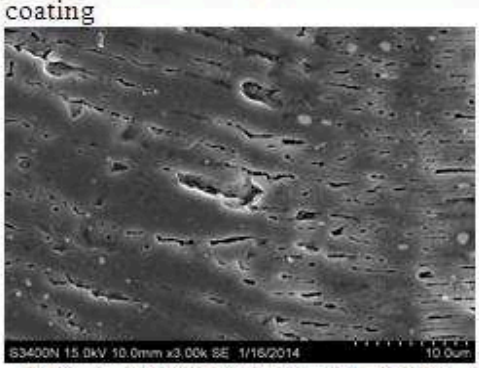

Fig. 5 SEM photograph of the amplified dendrites

3.3 The distribution of elements in the coating

Fig. 6 a) is the SEM photograph of columnar crystal in the middle coating. It can be seen from the figure, there were some bright spots in the internal of the columnar crystals. The columnar crystals and bright spots were analyzed by energy spectrum and the results were shown in Fig. 6 b, c). Combining XRD patterns and data in the table, it can be inferred that the main component of the columnar crystal was Al_2O_3. A small amount of chromium was dissolved in the aluminum. The remainder of chromium and iron aggregated in the form of solid solution.

During the solidification of molten products, alumina is the first to solidify to form a ceramic skeleton because of its highest melting point. Do to the high undercooling, the nucleation rate of metal is extremely high. What's more, the solidified aluminum would block the flow of molten products. In this way, metal elements are too late to escape and forced to dissolve in the ceramics. However, during the process of furnace cooling, staying at high temperature for about an hour provides a good opportunity for the diffusion of elements in solid state due to high temperature.

4 Conclusions

Al_2O_3-metal coating was successfully prepared on the carbon steel substrate using melting-casting method. The microstructure, the bonding status of the interface between the coating and the substrate, and the element distribution of the coating were studied, and the conclusions were dropped as follows:

(1)The coating combined the substrate well with no significant gaps or holes near the whole interface, mainly in mechanical occlusion and metallurgical combination in certain areas;

(2)The components and pores near the interface of coating distributed evenly, and pores were small shaped in round, showing a typical solidification loose structure;

(3)Columnar grain structure was obvious, and developed dendrite appeared in the top of some coarse columnar crystals;

(4)The metal elements mostly distributed in the grain boundary of massive phase or columnar crystals shaped in spherical.

Keywords: Graphene; Composite Materials; Supercapacitor

Abstract. In this paper, inorganic/graphene and polymer/graphene composites are mainly introduced. Compared to single component, the inorganic or polymer additions have great improvement on the electrochemical performance and provide the possibility of their application in supercapacitor. The latest application of graphene based composites in supercapacitor is overviewed as well.

Introduction

Graphene is composed of a single layer of carbon atoms connected together in the 2D plane with SP^2 hybrid orbitals. In graphene, each carbon atom forms three π bonds with the nearest three atoms and the formed C-C bond with strong energy has a rigid excellent structure. The excess P electron of each carbon atom perpendiculars to the plane of graphene, overlaps with its counterparts of the surrounding carbon atoms, and forms conjugated π bonds in the vertical of graphene plane. π electrons that can move freely makes graphene a higher electron mobility. Electrode material is the key material of a super capacitor and needed to be higher specific surface area, good conducting electrical conductivity. In general, the commonly used electrode materials are transition metal oxides (MnO, RuO, etc.), conductive polymers (polyaniline, polypyrrole, etc.) and carbon based active material with higher specific surface area (carbon nanotubes, activated carbon, etc.). The excellent properties of graphene will be drowned if it is made to be electrode material and that is to say that the properties of graphene are not fully used. Therefore, to meet the requirements of electrode materials of supercapacitor, graphene based composites with good conductivity and large surface area with the synergistic effect should be developed to really release the excellent performances of graphene.

Application of inorganic/graphene composites in the supercapacitor

$Co(OH)_2$/graphene composites prepared with ethylene glycol as solvent and ammonia as precipitant by the solvent thermal method has a higher capacitance of 518 F/g than the values of 37 F/g of graphite oxide and 25 5F/g of pure Co $(OH)_2$ when the load ratio is 1:10. Moreover, the particles on the surface of the loads and graphite are of the same size and exhibit a uniform distribution. For the Ni $(OH)_2$/ graphene composite material, the ratio of raw material has great influence on the electrochemical properties of the composite. With the concentration increase of $Ni(NO_3)\cdot 6H_2O$, the specific capacitance of composites increases firstly and then decreases, and the maximum capacitance value is 677 F/g. The same tendency of the specific capacitance appears with the increase of reaction time, and it is 688 F/g when the reaction time is 12h[1]. The electrochemical performances of A_3O_4/GNs composites were tested and the specific capacitances of Fe_3O_4/GNs, CO_3O_4/GNs and Mn_3O_4/GNs are 358, 240 and 708 F/g respectively, while the corresponding energy density are 10, 7 and 20 Wh/kg, respectively. After 1000 times of the charge and discharge for the three materials, the capacitors amount to 67.8%, 95.8% and 73% of their previous values. The good electrochemical performance of A_3O_4/GNs reveals has wide application prospect in the field of the supercapacitor [2]. Increases the power density to 5000 W/kg,

the energy density of RuO_2/GR composites can reach to 15.7Wh/kg, while the value of RuO_2 is only 5.8Wh/kg. As shown from the experimental results, the unique particle-lamellar structure of composite can improve the migration rate of ions, increase the energy storage density and exhibit excellent performances of charge discharge [3]. The specific capacitance of graphene/MnO_2 composites which prepared by microwave assisted synthesis method is 310 F/g under the scanning rate of 2mV/s and it is almost 3 times of the values of pure graphene (104 F/g) and pure MnO_2 (103 F/g) [4]. Graphene/MnO_2 composites prepared by electrodeposition method show excellent electrochemical performance and the specific capacitance is 476 F/g at a current density of 1A/g. Increasing the current density to 10A/g, the specific capacitance maintains at 216 F/g and the capacitance retention rate is 88%, which show the good ratio characteristics [5]. Graphene/Ni $(OH)_2$ composite material prepared by hydrothermal method is to deposit single Ni $(OH)_2$ nanosheets directly on the graphene capacitive performance and the specific capacitance can reach to 1335 F/g when charge discharge current density is 2.8A/g. The specific capacitance can remain to about 953F/g even under the high current density of 45.7A/g. In addition, there is no obvious decrease for the capacitance after a cycle of 2000 at 28.6A/g, which shows the excellent energy, power and cycle performances [6]. Nano Co_3O_4/ graphene composites were prepared by the precipitation and heat treatment process and the aggregation of Co_3O_4 nano sheets were effectively inhibited. The charge and discharge tests show that the specific capacitance of Co_3O_4 nano film are 203 F/g at 0.2 A /g and 173 F/g at 1 A /g and the specific capacitance retention rate is 85%. While the nano Co_3O_4/ graphene composites are 338 F/g at 0.2 A /g and 294 F/g at 1 A /g, and the specific capacitance retention rate is 87%. The the electrochemical activity of composites has a significantly improvement [7].

Application of polymer /graphene composites in the supercapacitor

Polymers can be easily attached to the surface or edge of graphene with covalent bond when they are composited with graphene. It breaks the van der Waals force and makes themodified graphene composite with good conductivity and wide application in the supercapacitor [8]. The electrochemical-capacitance performance tests show that the composites of GSP118 prepared with the ratio of graphene oxide: tin dioxide: aniline ratio of 1:1:8 was good electrochemistry performance under a scanning rate of 5mV/s. The specific capacitance of GSP118 composite electrode can reach to 913.4 F/g while the GSP181 is 177.9 F/g and GSP154 is 467.9 F/g [9]. Using aniline and graphene oxide as raw materials and distributing the polyaniline evenly to the graphene layer, polyaniline / graphene composites were synthesized by electrochemical method. Its specific capacitances are 325 F/g at 0.5 A/g and 315 F/g at 1 A/g. After no less than 1000 times of charge and discharge cycles, the specific capacitance retention rate is still as high as 90%. Moreover, the discharge efficiency is extremely high and the electrolyte ions in the electrode are easy to be diffuse and migrate [10].With the aqueous electrochemical deposition of pyrrole monomer, sulfonated graphene, twelve alkyl basic sulfonic acid, sulfonated polymer / graphene composite thin films are prepared. Due to the addition of sulfonated graphene, the conductivity and electrochemical properties of polypyrrole films are significantly improved. When the ratio of sulfonated graphene in composites is 40%, the specific capacitance of the composite films is 285 F/g on the discharge rate of 0.5 A/g [11]. Enhanced electrochemical performance can be obtained by doping PPY with a small amount of GQD（Graphene quantum dots）and the PGQD50（PPY：GQD is 50:1）will be a good candidate for supercapacitor electrode with a competitive specific capacitance of 485 F/g [12]. Graphene/PPy composites that reduced by ethylene glycol exhibit good capacitance performance. In the H_2SO_4 of 1mol/L, the specific capacitance of the composites is 420 F/g at the current density of 0.5A/g. CFGO/PANI composites which prepared by the carboxyl functionalized graphene oxide/polyaniline (CFGO/PANI) show the excellent electrochemical capacitance performance and cycling performance. In the H_2SO_4 of 1mol/L, the specific capacitance of CFGO/PANI reaches to 525 F/g at the current density of 0.3A/g. After 200 cycles of the constant current charge-discharge, the capacitance retention rate is about 91% [13].

Conclusion

Excellent chemical properties, electrical properties and large specific surface area make graphene be potential material in numerous fields in just a few years. Graphene composites not only maintain original performance, but also show the excellent composite effect, which provides the possibility application prospects for graphene composites in supercapacitor.

Dielectric barrier discharge plasma reduced Pt catalysts supported on activated carbon and their electrocatalytic activity

Keywords: Pt/C, electrocatalyst, dielectric barrier discharge (DBD), atmospheric-pressure cold plasma, supported metal catalyst

Abstract. Atmospheric-pressure dielectric barrier discharge (DBD) plasma was used to fabricate Pt/C electrocatalysts. The influences of the pretreatment of the activated carbon support and the preparing method on the properties of the Pt/C electrocatalysts were investigated. The composition of the Pt/C samples was characterized by X-ray diffraction (XRD). The electrocatalytic activity of the Pt/C samples was evaluating by measuring the cyclic voltammograms. The results showed that higher dispersion of Pt nanoparticles was obtained on the activated carbon support pretreated by HNO_3, and higher reduction rate of Pt ions was obtained in Pt/C prepared by DBD plasma. As a consequence, the Pt/C samples with the activated carbon support pre-oxidized by HNO_3 and reduced by DBD plasma exhibited the highest electrocatalytic activity.

1. Introduction

Pt-based catalysts were widely employed in fuel cells as cathode electrocatalysts [1]. In order to improve their electrocatalytic activity, many efforts had been attempted, including selection of the supports and the preparing methods. Due to the functional groups on the surface of the supports, metal ions could be adsorbed and intercalated into the sheets and pores to form thermal stable composite materials [2-3]. As for the preparation method, cold plasma reduction had been demonstrated as a facile and green method in catalyst preparation [4-7]. However, these plasma reduction methods were usually operated under low pressure and (or) incorporated with sophisticated discharge systems.

In order to solve these problems, dielectric barrier discharge (DBD) cold plasma was employed. DBD was a simple and easily operated approach for generating atmospheric-pressure cold plasma, and has been used to reduce metal ions [8-9]. However, it has not been reported using atmospheric-pressure DBD cold plasma to prepare supported Pt catalyst on low-cost and easy to get activated carbon.

In this study, high performance Pt/C catalysts were successfully fabricated by a simple and environmentally-friendly DBD plasma reduction method, and the influence of the pretreatment of the activated carbon support was investigated.

2. Experimental

Prior to the Pt/C electrocatalysts preparation, the activated carbon (40-60 mesh, Beijing Guanghua Timber Mill.) was pretreated by two methods. One part of them was washed with deionized water and then dried at 120 ^{o}C for 2 h (denoted as C(W)). The other part was pre-oxidized with 30wt% HNO_3 at 85 ^{o}C for 5 h, and then washed by deionized water and dried at 120 ^{o}C for 2 h (denoted as C(H)).

The activated carbon was impregnated with H_2PtCl_6 (99%, Reagent No.1 Factory of Shanghai Chemical Reagent Co., Ltd, China) solution for 12 h and dried at 100 ^{o}C for 2 h. Then the resultant sample was treated by atmospheric-pressure dielectric barrier discharge (DBD) cold plasma. In order to remove the chloride ions, the Pt/C catalysts prepared by DBD plasma were calcined at 300 ^{o}C in H_2 for 2 h (denoted as Pt/C(H)-PC and

Pt/C(W)-PC). For comparison, Pt/C(H)-C sample was prepared by H_2 calcination at 300 ^oC in H_2 for 2 h. All the loading amounts of metal Pt were 5.0wt% in this study.

The atmospheric-pressure DBD plasma device for preparing Pt/C catalyst was the same as described in our previous paper [10]. Both of the high-voltage electrode and the ground electrode were stainless steel plates (Φ=50 mm). A reaction cell made of quartz was placed between the electrodes. The discharge gap was 4 mm. The plate-to-plate DBD employed in this experiment was powered by a sinusoidal high voltage of 36 kV (peak-to-peak) at a frequency of 14.1 kHz without extra heating (CTP-2000K, Nanjing Suman Electronic Co. Ltd). The mixture of Ar and H_2 with a constant total flow rate of 100 ml·min^{-1} (F_{Ar}: F_{H2} = 1: 1) was used as working gases. The treatment was performed for 6 min.

The composition and crystalline nature of the Pt/C samples prepared by different methods and (or) supported on activated carbon treated by different methods were characterized by X-ray diffraction (XRD) using a DX-2700 diffractometer (Dandong Fangyuan, China) with graphite-monochromatized Cu $K_{\alpha1}$ radiation (λ=1.54178 Å).

Electrochemical measurements were performed with a CHI 600C electrochemical workstation (Shanghai Chenhua Apparatus) at room temperature.

3. Results and Discussion

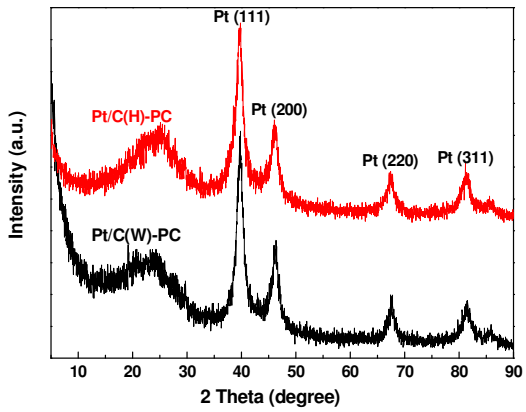

Fig. 1. XRD patterns of Pt/C(H)-PC and Pt/C(W)-PC prepared by DBD plasma with activated carbon treated by water or HNO_3

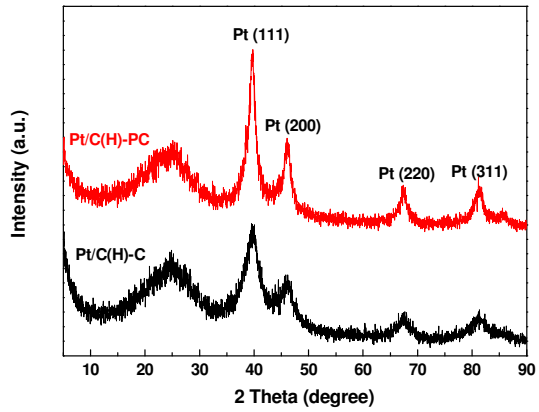

Fig. 2. XRD patterns of Pt/C(H)-PC and Pt/C(H)-C prepared by DBD plasma or thermal reduction

In order to investigate the influence of the pretreatment of the activated carbon support on the properties of the Pt/C catalysts, XRD patterns of Pt/C(W)-PC and Pt/C(H)-PC prepared by DBD plasma with activated carbon treated by water or HNO_3 were shown in Fig. 1. The broad diffraction peaks at 25.0^o for the samples exhibited carbon structure of activated carbon. Peaks associated with Pt (PDF # 04-0802) were observed at 39.8^o (111), 46.4^o (200), 67.8^o (220) and 82.4^o (311) in both of the samples. Compared with Pt/C(H)-PC, agglomeration of Pt nanoparticles appeared for Pt/C(W)-PC. This may be ascribed to the fact that the activated carbon pre-oxidized by HNO_3 was positively charged and the $PtCl_6^{2-}$ ions were uniformly absorbed on its surface, thereby highly dispersed Pt nanoparticles were obtained in Pt/C(H)-PC.

Fig. 2 represented the XRD patterns of Pt/C(H)-PC and Pt/C(H)-C prepared by DBD plasma or thermal reduction. As shown in Fig. 2, the characteristic peaks corresponding to Pt in Pt/C(H)-C were weaker than that in Pt/C(H)-PC, which indicated that a low reduction rate of Pt ions in Pt/C(H)-C was obtained. This may be due to the fact that many oxygen-containing groups were formed on the surface of activated carbon after HNO_3 treatment. These oxygen-containing groups may lead to the low reduction rate of Pt ions [11]. While the Pt/C(H)-PC sample underwent two

reduction processes, DBD plasma reduction and thermal reduction, and therefore a high reduction rate was obtained.

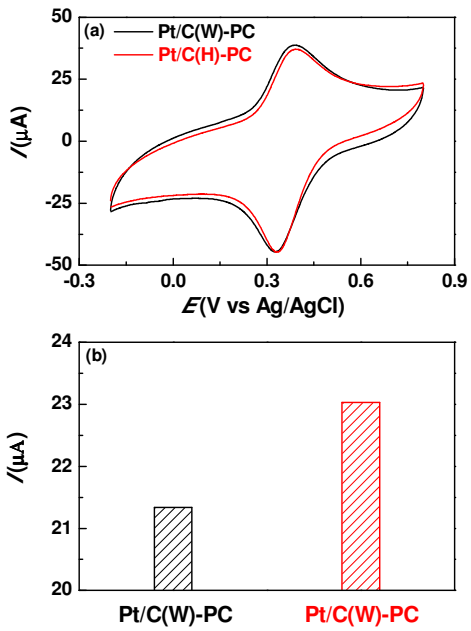

Fig. 3. (a) Cyclic voltammograms of Pt/C(H)-PC and Pt/C(W)-PC and (b) corresponding currents

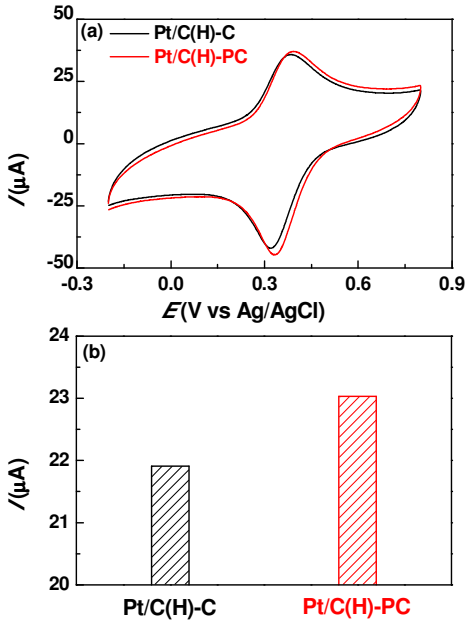

Fig. 4. (a) Cyclic voltammograms of Pt/C(H)-PC and Pt/C(H)-C and (b) corresponding currents

In order to investigate the influence of the pretreatment of the activated carbon support on the electrocatalytic activity of the Pt/C catalysts, cyclic voltammograms of Pt/C(H)-PC and Pt/C(W)-PC and corresponding currents were represented in Fig. 3. It can be seen that high electrocatalytic activity were obtained in both of the two samples, and the Pt/C(H)-PC sample exhibited higher activity than Pt/C(W)-PC, which may be attributed to the small size of Pt nanoparticles (Fig. 1). This indicated that the surface properties of activated carbon played an important role in preparing high dispersion of Pt nanoparticles to obtain high performance Pt/C electrocatalyst.

The cyclic voltammograms of Pt/C(H)-PC and Pt/C(H)-C prepared by DBD plasma and thermal reduction, and corresponding currents were collected and shown in Fig. 4. Pt/C(H)-PC gave an excellent electrocatalytic activity than Pt/C(H)-C, which may be due to the fact that a high reduction rate of Pt ions was obtained in Pt/C(H)-PC (Fig. 2).

In summary, the pretreatment of the activated carbon support play an important role to obtain small size of Pt nanoparticles and atmospheric-pressure DBD plasma was efficient to prepare high performance Pt/C electrocatalyst.

4. Conclusion

High performance Pt/C electrocatalysts were prepared by DBD plasma. The results showed that higher dispersion of Pt nanoparticles was obtained on the activated carbon support pretreated by HNO_3, and higher reduction rate of Pt ions was obtained in Pt/C prepared by DBD plasma. As a consequence, the Pt/C samples with the activated carbon support pre-oxidized by HNO_3 and reduced by DBD plasma exhibited the highest electrocatalytic activity. In conclusion, pretreatment of the activated carbon support play an important role to obtain small size of Pt nanoparticles and atmospheric-pressure DBD plasma was an efficient method to prepare high performance Pt/C electrocatalyst.

Keywords: Au, CO oxidation, dielectric barrier discharge (DBD), atmospheric-pressure cold plasma

Abstract. Atmospheric-pressure dielectric barrier discharge (DBD) cold plasma was used to prepare high performance Au/P25 catalysts (Au/P25-P). XRD and UV-Vis DRS spectra for Au/P25 catalysts were performed. The results indicated that the size of Au nanoparticles in Au/P25-P was smaller than that prepared by conventional thermal impregnation method (Au/P25-H). The temperature-dependent CO oxidation was performed to investigate the activity of Au/P25 catalysts. Au/P25-P gave excellent catalytic activity for CO oxidation than that of Au/P25-H. This may be attributed to the smaller size of Au nanoparticles in Au/P25-P.

1. Introduction

Gold nanocatalysts had drawn much research attention since the pioneering work of Haruta in the 80 s of last century [1]. It had been reported that the optimized size of gold nanoparticles in CO oxidation reaction was ~3 nm [2]. However, it was still a challenge to prepare small size of Au nanoparticles.

Recently, atmospheric-pressure cold plasma techniques had attracted significant attention for preparation of supported metal catalysts since they didn't require sophisticated discharge and vacuum systems. Dielectric barrier discharge (DBD) was a simple and easily operated approach for generating atmospheric-pressure cold plasma, and had been used to reduce metal ions [3-4]. For example, Kim et al. [3] prepared supported metal Pt catalyst by using atmospheric-pressure DBD cold plasma to reduce supported Pt metal ions. The plasma catalytic reaction for methane conversion showed positive characteristics to produce light alkanes when Pt catalyst was used after atmospheric-pressure DBD cold plasma treatment. In our previous work [5-6], atmospheric-pressure DBD cold plasma was successfully applied to fabricate Ag/TiO_2 and Pt/TiO_2 photocatalyst. The results showed that the sizes of Ag and Pt nanoparticles in Ag/TiO_2 and Pt/TiO_2 prepared by atmospheric-pressure DBD cold plasma were smaller than that prepared by conventional method, and the photocatalysts exhibited high activity for methylene blue degradation. These results showed that atmospheric-pressure DBD cold plasma does well in fabricating supported metal catalysts with small size of metal nanoparticles.

In this study, Au/P25 catalysts were prepared by atmospheric-pressure DBD cold plasma using Ar and H_2 mixture gases as working gas. The size of Au nanoparticles in Au/P25 prepared by DBD plasma was smaller than that prepared by conventional method, and they gave excellent catalytic activity for CO oxidation.

2. Experimental

Commercially produced TiO_2 powder was obtained from Degussa (P25 powder). Degussa P25 contains 75% anatase and 25% rutile with a specific BET-surface area of 50 $m^2 \cdot g^{-1}$ and primary particle size of 20 nm [7]. The Au/P25 catalysts were prepared by deposition-precipitation with DBD plasma reduction method (denoted as Au/P25-P) and a conventional thermal impregnation method (denoted as Au/P25-H), respectively. A certain amount of $HAuCl_4$ solution (10 $g \cdot L^{-1}$) was first mixed with 2.0 g P25 and 80 ml deionized water, and then a certain amount of urea with a molar ratio of gold to urea at 1/200 was added as the precipitation agent. The mixture was stirred at 80 ^oC for 8 h and aged for 12 h at room temperature. Subsequently, the precipitate was filtrated from the

solution and dried at 80 °C for 6 h. Finally, Au/P25-P was obtained by reducing the powder with atmospheric-pressure DBD plasma. For comparison, Au/P25 by thermal impregnation method was prepared (denoted as Au/P25-H). The P25 powder was impregnated with $HAuCl_4$ solution for 24 h and dried at 100 °C for 2 h. Then it was reduced in flowing hydrogen gas for 2 h to obtain Au/P25-H catalyst.

The atmospheric-pressure DBD plasma device for preparing Au/P25-P was the same as described in our previous paper [8]. Both of the high-voltage electrode and the ground electrode were stainless steel plates (Φ=50 mm). A reaction cell made of quartz was placed between the high-voltage electrode and ground electrode. The discharge gap was 4 mm. The power source (CTP-2000K, Nanjing Suman Electronic Co. Ltd) was capable of supplying a bipolar sine wave output with 0-40 kV peak-to-peak voltage ($U_{p\text{-}p}$) at a frequency of 7.5-30 kHz. The mixture of Ar and H_2 with a constant total flow rate of 100 ml·min^{-1} (F_{Ar}: F_{H2} = 1: 1) was used as working gases. The treatment was performed for 6 min.

The composition and crystalline nature of the Au/P25 samples were characterized by X-ray diffraction (XRD) using a DX-2700 diffractometer (Dandong Fangyuan, China) with graphite-monochromatized Cu $K_{\alpha 1}$ radiation (λ=1.54178 Å). UV-Vis DRS spectra of the Au/P25-P samples were measured by a UV-Vis spectrophotometer (Varian Cary 100, USA) with a $BaSO_4$ plate as the reference.

The temperature-dependent CO oxidation was performed in a quartz tube (4 mm i.d., 6.0 mm o.d.) at atmospheric pressure with 10 mg catalyst. The reaction was started in flowing CO/O_2 mixture (1.0 vol.% CO, 20.0 vol.%O_2, balance N_2) with a 20 ml·min^{-1} flow rate over the temperature range of 30-300 °C. All data were acquired after 30 min reaction time to allow the attainment of steady state. The effluent was then analyzed online by a gas chromatograph (Agilent 7890) equipped with a TDX-01 column and a thermal conductivity detector (TCD).

3. Results and Discussion

The plate-to-plate DBD employed in this experiment was powered by a sinusoidal high voltage of 36 kV (peak-to-peak) at a frequency of 14.1 kHz without extra heating. The voltage waveforms of the plate-to-plate DBD were shown in Fig. 1a. The corresponding Lissajous figure of the plate-to-plate DBD, as indicated in Fig. 1b, gives 65.6 W of the electric discharge power.

Fig. 2 represented the XRD patterns of P25, 2%Au/P25-P and 2%Au/P25-H. After loading Au nanoparticles, the characteristic peaks corresponding to P25 were weakened. Cubic phase of Au (JCPDS card No. 00-004-0784) was observed in both of the 2%Au/P25-H and 2%Au/P25-P samples. The strong characteristic peaks indexed to Au in 2%Au/P25-H may be attributed to the aggregation of Au nanoparticles. Interestingly, these peaks were weakened in 2%Au/P25-P, which indicated that DBD plasma were highly efficient for preparing small size Au nanoparticles.

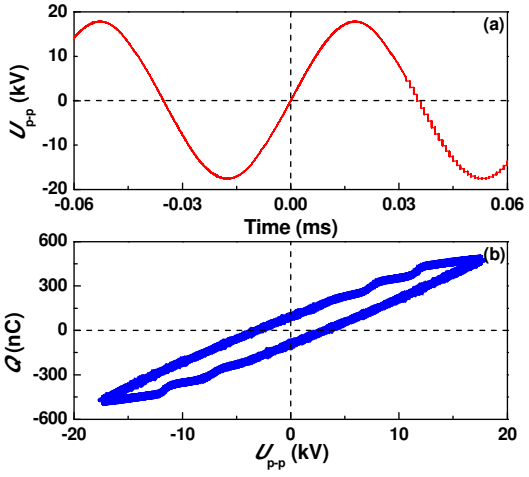

Fig. 1. (a) The waveform of discharge voltage and (b) corresponding Lissajous figure of the DBD for preparation of Au/P25-P

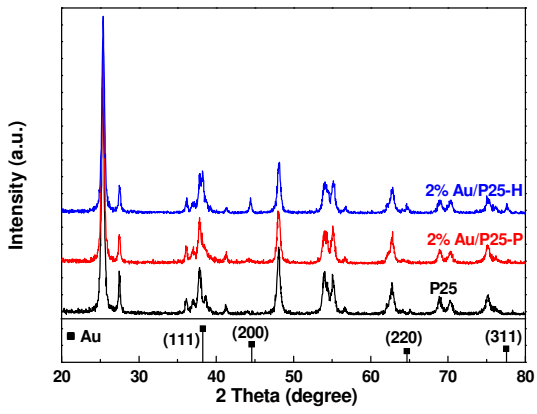

Fig. 2. XRD patterns of P25, 2%Au/P25-P and 2%Au/P25-H

The UV-Vis DRS spectrum for the 1%Au/P25-P sample prepared by atmospheric-pressure DBD cold plasma was shown in Fig. 3. The characteristic absorption around 560 nm was attributed to the surface plasmon resonance peak of the spatially confined electrons in Au nanoparticles [9]. This absorption spectrum indicated that metal Au nanoparticles were present after plasma treatment. Meanwhile, this band was very weak in 1%Au/P25-P compared with previous work, which indicated that small size of Au nanoparticles was obtained by DBD plasma. This was consistent with the results of XRD analysis.

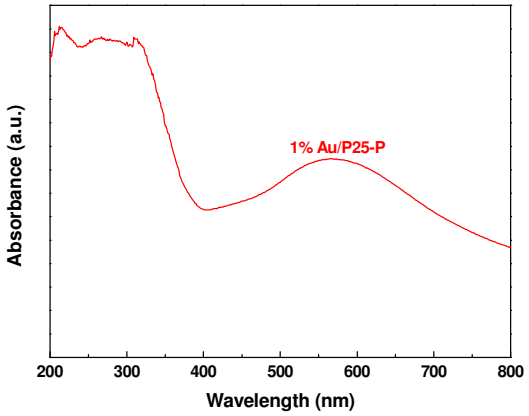

Fig. 3. The UV-Vis DRS spectrum for 1%Au/P25-P prepared by DBD plasma

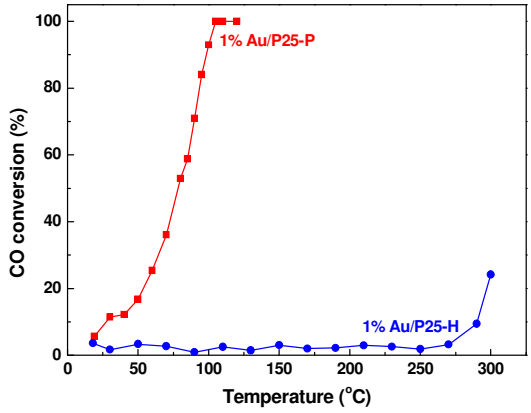

Fig. 4. Catalytic activity for CO oxidation with 1%Au/P25-P and 1%Au/P25-H

Fig. 4 showed the CO oxidation activity of 1%Au/P25-P and 1%Au/P25-H in the temperature range of 30-300 °C. Under the reaction conditions, the CO conversion increased gradually with the increase in temperature. Besides, a sharp increase could be observed for 1%Au/P25-P and the 100% CO conversion temperature was 105 °C, while the CO conversion over 1%Au/P25-H started at about 290 °C. The difference in catalytic activity over 1%Au/P25-P and 1%Au/P25-H may be ascribed to the influence of the size of Au nanoparticles.

In summary, atmospheric-pressure DBD plasma was efficient for preparing high catalytic activity Au/P25 with smaller size of Au nanoparticles. Further progresses will be reported in our future works.

4. Conclusion

High performance Au/P25 catalysts were prepared by atmospheric-pressure dielectric barrier discharge (DBD) cold plasma. The results of XRD and UV-Vis DRS spectra indicated that the size of Au nanoparticles in Au/P25-P was smaller than that for Au/P25-H. The results of the temperature-dependent CO oxidation test exhibited that Au/P25-P gave excellent catalytic activity for CO oxidation than that of Au/P25-H, which may be attributed to the smaller size of Au nanoparticles in Au/P25-P. Atmospheric-pressure DBD cold plasma was efficient for preparing high performance Au/P25 catalysts for CO oxidation.

Keywords: Kinetics; Inverse Emulsion Copolymerization; Dimethyl Diallyl Ammonium Chloride;

Abstract. Inverse emulsion copolymerization of DMDAAC with AM has been investigated by the dilatometer technique using the mixture of Span-80 and Tween-80 as the composite emulsifier and 2,2'-azobis(2-methylpropionconidine) dihydro chloride as the initiator. In inverse emulsion copolymerization, the influences of the concentrations of monomers, emulsifier and initiator and initial temperature on polymerization rate and the intrinsic viscosity of polymer have been examined. Its kinetics can be expressed as $R_p \propto [M]^{2.11}[I]^{1.21}[E]^{0.48}$, $[\eta] \propto [M]^{0.87}[I]^{-0.30}[E]^{0.36}$. The overall activation energy for the rate of polymerization was determined with a dilatometer as 20.33 kJ/mol over the temperature range 35-55℃.

1. Introduction

The cationic copolymer of dimethyl diallyl ammonium chloride (DMDAAC) and acrylamide (AM) has the merits of high molecular weight, good water-solubility, wide usable pH range etc. Therefore it is widely used in the areas of oil exploitation, paper making, mining, printing and dyeing of textiles, daily chemical industry and slurry dehydration, etc. Current main method to produce PAM-DMDAAC is solution polymerization [1]. However, at the end of the solution polymerization, the viscosity of the polymer solution is large, and a gel is easily formed. Therefore, it is difficult to produce the polymer with high concentration and high molecular weight [2]. If the product is turned into a powder, the drying process will consume more energy. Agglomeration often happens, and the quality of the product is poor, which is a familiar problem during solution synthesis of polymers. At present, there are many methods to synthesize the polymer; the more successful one is inverse emulsion polymerization, with which the polymer has the merits of high molecular weight and high content. This method solves the problem of solution polymerization. However, a description of the fundamental polymerization kinetics is scarce in the literature [3].

In order to research the free radical copolymerization theoretically, the kinetics studies of inverse emulsion polymerization were made in this work. In this paper the effects of the reaction parameters on the conversion, intrinsic viscosity and polymerization rate were investigated and the dependence of polymerization rate and intrinsic viscosity on monomer, initiator and emulsifier concentrations were determined. Based on the experimental results, the polymerization mechanisms were discussed.

2. Experimental

2.1. Materials

The monomers AM (40% in water), DMDAAC (60% in water) and 2,2'-azobis(2-methylpropionconidine)dihydro chloride (V50) were kindly provided by Binzhou chemical Co. Ltd. (Shandong province, China). The emulsifier is a blend of Span-80 and Tween-80 both provided by Shanghai Guoyao Co. The oil is kerosene which was filtered before use. The

following chemicals obtained from Guangmang Chemical Co. were of analytical-grade and used as supplied: sodium acetate (HCOONa), sodium chloride (NaCl), poly(vinylpyrrolidone) (PVP), N, N, N', N',-tetramethyl-ethylenediamine (TMEDA), ethanol, acetone, ethylene diamine tetraacetic acid (EDTA). Deionized water was used throughout.

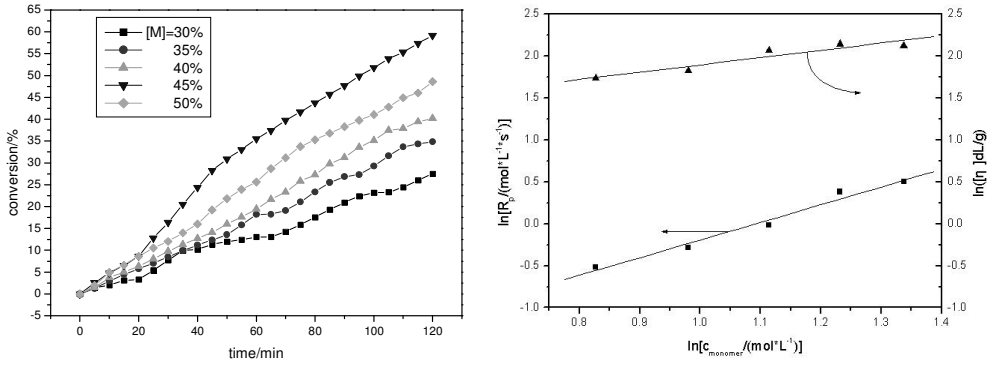
2.2. Copolymerization

Varying quantities of the reagents were added to a 500-mL four-neck round bottom flask equipped with an anchor-like paddle stirrer, a thermometer and a nitrogen inlet tube. After purging with N_2 for 30 min and controlling the temperature at 40°C in a water bath, the polymerization was initiated by injecting the initiator into the reaction mixture under stirring and performed for a given reaction time. The reaction time was controlled to give conversions less than 10 wt% to satisfy the differential copolymerization equation. After the desired time the copolymers were separated by precipitation in ethanol and acetone mixture (volume ratio of 1:1), and was washed with fresh acetone. These operations were repeated several times to remove the unreacted monomers. The copolymer was finally dried under vacuum at 40°C to constant weight. The intrinsic viscosity was measured in 1M NaCl aqueous at 30±0.05℃ using an Ubbelhode viscometer. The polymer conversion was recorded as a function of time with a dilatometer, and the polymerization rate (R_p) was obtained from further differentiation. In this paper, the concentrations of initiator and emulsifier are reported as weight percent based on the monomer and the total solution, respectively.

3. Results and Discussion

In this study, the influences of various polymerization parameters, including the initial temperature, and monomer [M], emulsifier [E] and initiator [I] concentrations were investigated systematically. The standard recipe used in this study is given as follows: [M] = 45% of total, n_{AM} / n_{DMDAAC} = 8/2, $T_{initiation}$ = 40℃, [E] =8% of total, [I] = 0.05% (monomer). The amount of each ingredient was kept constant in all experiments excepted as indicated.

3.1. Effect of monomer concentration on copolymerization



(a) (b)

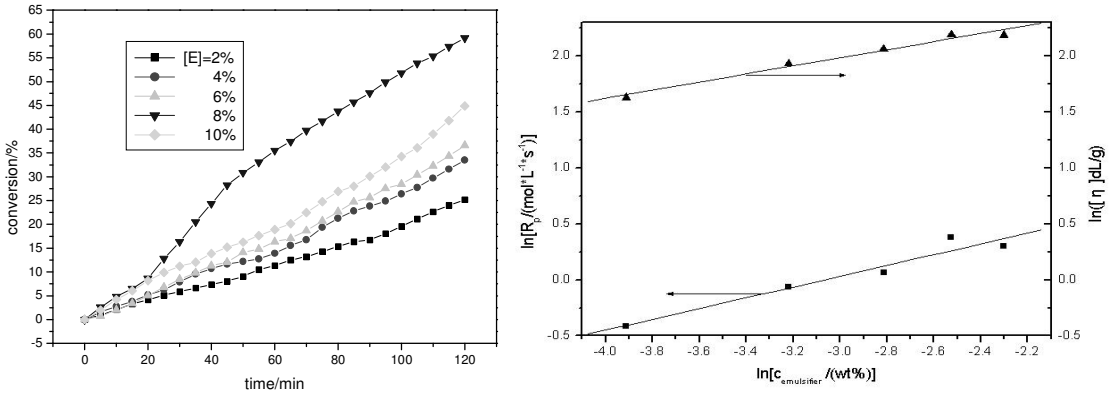
Fig.1. (a) Conversion vs. time curves at different monomer concentrations; (b) the effect of monomer concentration on polymerization.

Fig. 1 (a) and (b) show the dependence of the conversion on the reaction time at various monomer concentrations and the effect of monomer concentration on polymerization kinetics, respectively. As shown in Fig. 1, conversion, polymerization rate and intrinsic viscosity increase with the increase of monomer concentration. The higher the monomer concentration is, the higher the diffusion rate of monomer to microsphere or free-radical active center is, and then conversion, polymerization rate and intrinsic viscosity increase. The effect of monomer concentration on

polymerization rate and intrinsic viscosity can be calculated as: $R_p \propto [M]^{2.11}$, $[\eta] \propto [M]^{0.87}$. The higher monomer order is due to the fact that the gel effect becomes more and more influential with the increase of monomer concentration.

3.2. Effect of emulsifier content on copolymerization

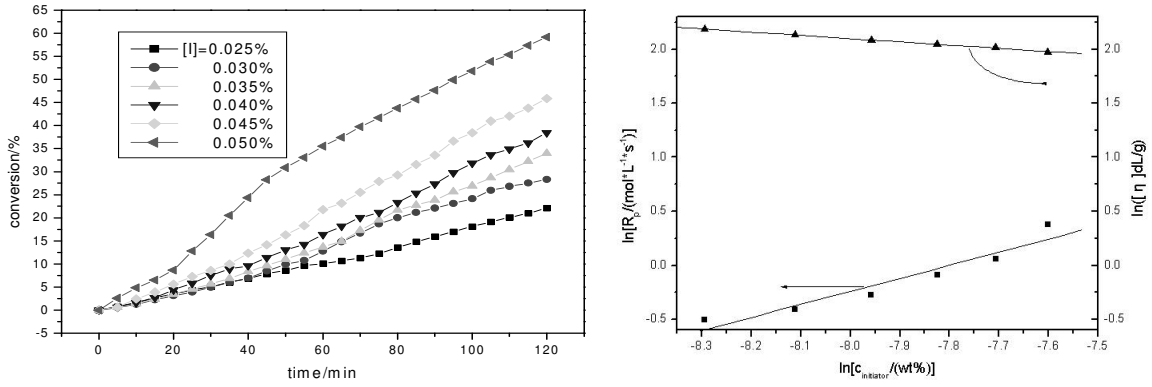
In the present system, the mixture of Span-80 and Tween-80 is used as a composite emulsifier. Fig. 2 displays the effect of emulsifier content on polymerization. The overall polymerization rate increased with the increase of emulsifier content. The effect of emulsifier content on polymerization kinetics is displayed as: $R_p \propto [E]^{0.48}$, $[\eta] \propto [E]^{0.36}$. Higher emulsifier content causes faster emulsifier adsorption, and hence for a given duration a greater number of smaller particles will be emulsified during the primary emulsifying process. As a result, the total interfacial area will be larger, the capture efficiency of primary radicals will rise and the reaction rate will increase.



(a) (b)

Fig.2. (a) Conversion vs. time curves at different emulsifier contents; (b) the effect of emulsifier content on polymerization.

3.3. Effect of initiator content on copolymerization

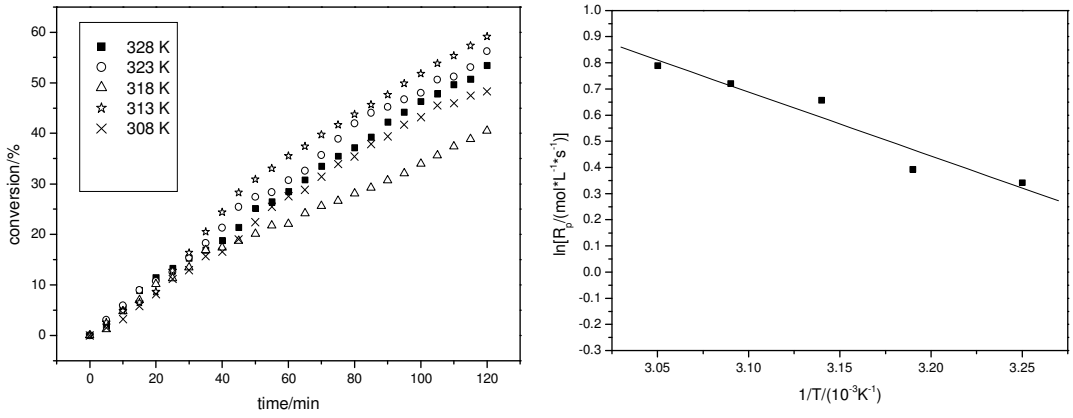


(a) (b)

Fig.3. (a) Conversion vs. time curves at different initiator contents; (b) the effect of initiator content on polymerization.

It was found in Fig. 3 that $R_p \propto [I]^{1.21}$, $[\eta] \propto [I]^{-0.30}$. The overall R_p increases with the increase of initiator content. However, intrinsic viscosity of the polymer formed is found to decreases with increasing initiator content. As the initiator content increases, the rate of free radical formation becomes greater, which leads to faster monomer consumption but also results in a shorter kinetic chain length.

3.4. Effect of polymerization temperature on copolymerization



(a) (b)

Fig.4. (a) Conversion vs. time curves at different initial temperature; (b) the effect of initial temperature on polymerization.

The effect of temperature on the polymerization rate is shown in Fig. 4 (b). With increasing temperature, the radical concentration increases, resulting in an increase in the polymerization rate. According to the Arrhenius equation, the overall activation energy of the present polymerization system ([M] = 45% of total, n_{AM} / n_{DMDAAC} = 8/2, [E] =8% of total, [I] = 0.05% (monomer)) is 20.33 kJ/mol calculated by plotting $\ln R_p$ versus 1/T (K) (shown in Fig. 4 (b)). This value corresponds well with the typical activation energies of propagation in free radical polymerization [4][5]. The lower activation energy of polymerization was attributed to the small energy barrier for the absorption of free radicals by latex particles and it was controlled by the initiation and propagation reactions.

4. Conclusion

In this paper, the influences of the concentrations of monomers, emulsifier and initiator and initial temperature on conversion, polymerization rate and intrinsic viscosity of polymer in inverse emulsion polymerization have been examined. The intrinsic viscosity increased with the increasing concentrations of monomers and emulsifier and the decreasing concentration of initiator. The rate of polymerization (R_p) can be represented by $R_p \propto [M]^{2.11}[I]^{1.21}[E]^{0.48}$. The overall activation energy for the rate of polymerization was determined with a dilatometer as 20.33 kJ/mol over the temperature range 35-55℃.

Keywords: large strain machining, rake angle, multi-deformations, FEM

Abstract. Formation of chip is a typical severe plastic deformation progress in machining which is only single deformation stage. The rake angle of tool is governing parameter to create large strain imposed in the chip. Effect of rake angle and deformation times on effective strain, mean strain, strain variety and strain rate imposed in the chip are researched respectively. The result of simulation have shown that the chip with large strain and better uniform of strain along the longitudinal section of chip can be produced with negative rake angle at some lower cutting velocity by multi-deformations in large strain machining.

Introduction

Formation of chip is a typical severe plastic deformation progress in machining with only single deformation stage. Large plastic strain(1-15) can be imposed in the chip by changing the rake angle of tool, with the wore highly strained chips being generated using tools with more negative rake angles. S.Swaninathan[1-2] reported that OFHC chips which were structured by nanoscale equaixed grains with a significant of high-angle grain boundaries can be received at the speed of 0.02m/s with the tool rake angle of -20°. The vickers hardness of the chips were substantially increased from 50 to 155. While at the speed of 0.01m/s with the tool rake angle of -20°, Al6061 chips were structured by nanograins with 75nm. The chip materials with ultrafine grained and high hardness can be produced with negative tool rake angle at some lower cutting velocity.

Since the application of FEM in machining has been receiving much attention since 1970s, FEM has become the main tool for simulation metal cutting progress with result in plastic deformation of metal materials. M.SEVIER[3] studied the influence of the rake angle and friction at the tool-chip interface on the deformation by FEM. They found that the result of FEM on strain, stress, strain rate and machining temperature in the deformation area are consistent with the result of PIV analysis. W.J.Deng[4] analyzed the effect of rake angle on distribution of effective strain imposed in chips by FEM and found that the distribution of effective strain is consistent with microstructure of chips. In this paper, machining model of large negative rake angle and edge radius of tool is established in order to reveal the formation mechanics on nanostructured chips by multi-deformations based on FEM.

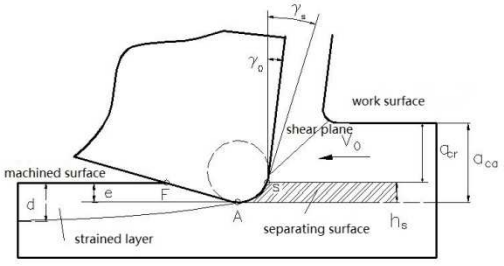

Fig.1 Machining model of large negative rake angle and edge radius of tool

Figure 1 shows the machining model of large negative rake angle and round cutting edge radius of tool. There are three deformation areas during the progress of chip production in the large strain

machining. The chips are produced in the first deformation area under the shear and extraction by large negative rake angle of tool in the large strain machining. In the second deformation area, the chips are undergone extraction and friction from rake flank of tool during they flow along the rake flank and received more sever plastic deformation. In the third deformation area, metal of cutting layer under the shunting point are severely extruded by cutting egde radius of tool, rounded nadir A of cutting edge and sever frictional with rake flank of tool so as to strained larger with sever fibrosis are founded in the work surface which physical and mechanical properties are changed.

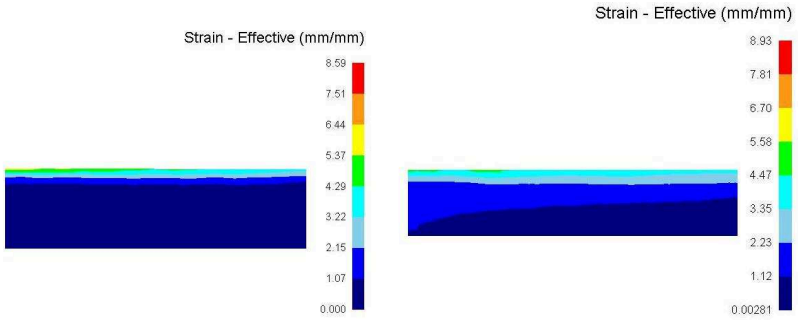

Fig.2 Distribution of effective strain in strained layer

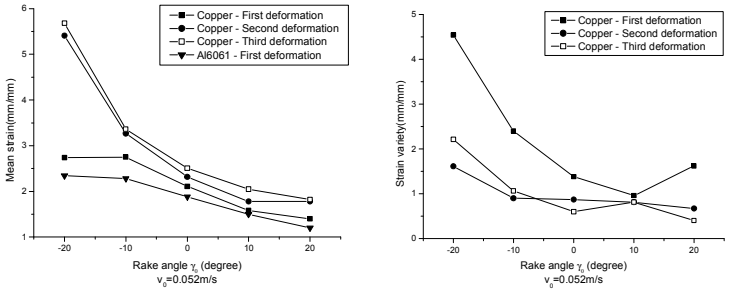
Figure 2 states the distribution of effective strain in strained layer. The height of strained layer is about 0.185mm after the first deformation by the large strain machining with rake angle of -20°. While the height of strained layer is substantially increased from 0.185 to 0.5mm in the third deformation and while the maximum value of effective strain is about 5 in the two deformations. The chip material with larger strain and the improvement of the uniform shear strain distribution in the chip on longitudinal section are produced under the effect of multi cumulative strain.

Result

The simulation of machining was done at the speed of 0.052m/s, with tools of rake angles in the range from 20° to -20° in order to examine the effects of rake angle on the strain, stress and strain rate imposed in the chips and the uniform distribution of shear strain.



(a) (b)

Fig.3 Influence of rake angle on shear strain of chip (a) rake angle-mean strain. (b) rake angle-strain variety.

Figure 3 states the influence of rake angle on shear strain of chip during three deformation stages. The max of effective shear strain are 2.24, 3.02, 4.26 and 5.34 at the rake angle of 10°, 0°, -10°, and -20° respectively in the first deformation. The thickness of chip and the difference of chip form are increased with the decreased rake angle. With more decrease rake angle of tool, the mean strain and strain variety are a little increased in the range of 20°, 10° and 0°. While at the larger negative rake angle, they are substantially increased. Although compared the first deformation, the max of effective strain are only a little increased with the increase of deformation times at the rake angle of 10°, 0°, -10°, the mean value of effective strain is greatly increased and strain variety is greatly decreased along the longitudinal section of chip in the second and third deformation. The

distributions of shear strain are more uniform along longitudinal section of chip. Especially at the rake angle of $^{-20^{\circ}}$, the max value and mean value of effective strain are increased from 5.34, 2.74 in the first deformation to 7.12, 5.68 in the third deformation respectively and the strain variety is decreased from 4.54 to 2.11. It is showed that with the decrease of rake angle, the mean strain and strain variety are a little increased, but at the more negative rake angle, the mean strain is more substantially increased and strain variety is more decreased. Compared the first deformation, at the rake angle of $^{-20^{\circ}}$, the mean strain of chips are substantially increased and the strain variety are decreased by multi deformation which can improve the uniform distribution of strain and microstructure along the longitudinal section of chip. While the effect of deformation times do little to effective stress of deformation area.

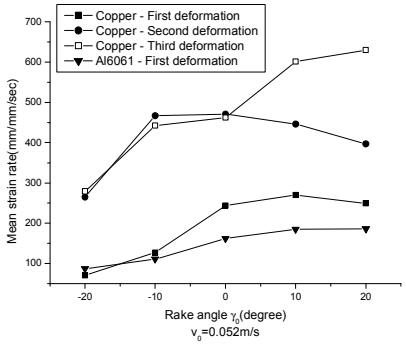


Fig. 4 The effect of rake angle on mean effective strain rate of chips in shear area

Figure 4 shows the effect of rake angle on mean effective strain rate of chips in shear area. With the decreased rake angle, the mean strain rate is decreased at the negative rake angle. Compared the first deformation, the mean effective strain rate are more increased in multi-deformations. At the rake angle of different range, the mean effective strain rate are increased from 249,270,244,127and 70mm/mm/sec in the first deformation to 630,610,462,446 and 279mm/mm/sec in the third deformation at the rake angle of $20°$,10°, 0°, -10° and -20° respectively. It is showed that the strain rate of chips in shear area is higher than the strain rate of material produced by conventionally methods of Severe Plastic Deformation.

Summary

The rake angle of tool is a governing parameter in large strain machining in which chip formation mechanism, strain, strain rate and uniform of strain distribution.

Compared the first deformation, the strain and uniform of strain are improved in the second and third deformation. The increased of deformation times change the machined material to be highly strained material which the chips with larger strain and better uniform of strain can be produced by multi-deformations.

The chip with large strain and better uniform of strain can be produced with negative rake angle at some lower cutting velocity by multi-deformations in large strain machining. The microstructure of chip produced by large strain machining can be greatly fined to be nanoscale which physical and mechanical properties can be substantially improved.

This research is supported by scientific research fund of HuBei provincial education department (No. Q20112602).

Keywords: Lasers and laser optics; Microchip laser; Pumping

Abstract. Single-frequency microchip lasers have been widely used in differential absorption radars, pulse coherent Doppler radars, pumping optical parametric oscillators, and etc. So theoretical analysis and experimental researches on the LD-pumped 2.09 μm microchip laser have important realistic meaning. According to quasi-three-level Cr, Tm, Ho: YAG(CTH:YAG) laser crystal working characteristics, the theoretical expression and relationship curve between the output optical power and 785nm LD-pumped power are obtained by theoretical calculating based on the pumping rate equation. The CTH:YAG crystal with 4mm diameter and 1 mm thickness is used to do experimental test. The corresponding three kinds of particle concentration are 0.85%, 5.9% and 0.36% respectively. When the crystal temperature is controlled at 10 ℃, microchip laser beam output characteristic curve is obtained under different pump spots. The results show that when the pump spot diameter is 75um the maximum single-frequency output power is 32mW and when the pump beam is 100um the maximum single-frequency output power is 30mW. The corresponding optical to optical conversion slope efficiencies are 6.8% and 6% respectively.

Introduction

The single-frequency, diode pumped, and solid-state lasers has been the investigated several decades[1], and the LD-pumped solid-state lasers with wavelength 2μm have been widely used in the areas such as laser medical science, remote sensing, coherent Doppler radar, and differential absorption radar areas [2-5]. Presently, lots of research reports about 2μm microchip lasers have been published [6-8]. There have been a variety of ways to realize 2μm single frequency, for example, Fabry-Perot etalon in the resonant cavity method [9], microchip laser resonant cavity method [10], non-planar ring cavity methods [11], and so on. Simply analyzing all the methods above, it can be easily found that the LD pumped microchip lasers have compact and simple structure characteristics, which is attracting lots of researchers to investigate the microchip lasers. In 1998, Frank F. Heine and his coworkers use external cavity feedback technology to achieve a wavelength tunable single-longitudinal-mode Tm: YAG laser, the wavelength tuning range of which is 15nm and single-frequency output power of 45mW. In 2001, C. Nagasawa and his research team obtained 11mW single longitudinal mode laser output based on a thickness of 0.9mm Tm, Ho: YLF microchip with the 1% output transmittance and 20℃ crystal temperature. In 2009, Beijing Institute of Technology theoretically and experimentally studied the affects of the pumping microchip laser spot size on the single-frequency characteristics in detail [10].

In this manuscript, we make theoretical and experimental investigations on the LD-pumped 2.09 μm microchip laser. Firstly, based on the quasi three-level rate equations the output power and pump power relations of the CTH: YAG laser is deduced and numerical simulation is given. Then, using the LD-pumped 2.09 μm microchip laser with 1mm thickness, the experimental results of the output power and pump power are obtained. At last, conclusions are given.

Principals

In CTH: YAG crystal, the Cr^{3+} and Tm^{3+} are photosensitive ions, and the Ho^{3+} is active ion. Because Cr^{3+} has two very broad absorption bands in the visible optical band, flash lamp is usually used to pump the CTH: YAG crystal. Under the flash lamp pumping condition, Cr^{3+} ion will

produce from $^4A_1$ to $^4T_2$ and $^4T_2$ transitions after absorbing the pumping light. After fast non-radiative relaxation to ^2E state, based on ion-dipole interaction, energy of the Cr^{3+} to ^2E level radiation is transferred to Tm^{3+}, which is transferred from the ground state to the $^3H_4$ state. $^3H_4$ state of Tm^{3+} ion is transferred to $^3F_4$ level through cross relaxation, which has a longer fluorescence lifetime. So the energy can be easily transferred to Ho^{3+} by resonance effect, which can transfer Ho^{3+} from ground state to $^5I_7$. By stimulated radiation, Ho^{3+} is transferred from $^5I_7$ to $^5I_8$ and photons are released, and then laser is generated. If LD pumping form is used, Tm^{3+} can be directly transferred from ground state to $^3F_4$ and the energy is transferred to Ho^{3+} ions, then laser is generated. Because the CTH: YAG crystal has 4nm absorption bandwidth around 785nm and at this wavelength the LD can easily obtain a larger output power at present, 785nm LD pumping technical solution is usually used to pump CTH: YAG or TH: YAG laser to produce a 2.09μm laser. In this case, the impact of the energy transfer between Cr and Tm is little, and the rate equation can only consider the interaction between Tm and Ho. TH: YAG is a quasi-three-level system, according to the reference [12], the rate equation can be written as following.

$$\frac{dN_x}{dt} = R\left(1-(1-f_{Ho})\frac{N_x}{N_{Tm}}\right)-\frac{N_x}{\tau}-k_{\Sigma Ho}N_x^2-\sigma c\left(f_{Ho}(f_u+f_l)N_x-f_lN_{Ho}\right)\Phi \tag{1}$$

where R is the pumping rate, N_{Tm} and N_{Ho} present the Tm and Ho doping concentrations respectively, τ_i present life of the particle energy level i, τ presents the life of laser upper level, k_{ijkl} is the up-conversion coefficient of the energy level i to energy level j and energy level k to energy level l, η_i is cross-relaxation efficiency of energy level i, β_{ij} is spontaneous emission scale factor of the energy level i, f_u and f_l are the upper and lower laser level Boltzmann scores, σ is emission cross section, $f_{Ho}=\frac{N_6}{N_x}$ presents the scale fraction of the total up-level particles of Ho, $k_{\Sigma Tm}$ is the total up-conversion coefficient of Tm, $k_{\Sigma Ho}$ is the total up-conversion coefficient of Ho, Φ is the cavity photon density, and c is the speed of light in vacuum. If laser works in continuous form, $\frac{dN_x}{dt}$ equals zero. The following expression can be obtained.

$$\frac{N_x}{N_{Tm}}=\frac{-(a_2P_1^2+2P_2P_3)\pm\sqrt{\left(a_2P_1^2+2P_2P_3\right)^2-\left(P_1^2-4P_2^2\right)\left(\left(a_1P_1\right)^2-P_3^2\right)}}{2\left[\left(\frac{P_1}{2}\right)^2-P_2^2\right]} \tag{2}$$

where P_p and P_L are the pump power and the output power of the laser, T is the transmittance of the output end, ω_p and ω_L are the radius of pump beam spot and oscillation beam spot, and the significances in detail of the other parameters can be referred to reference [12]. So we will not repeat them here. If another aspect is considered, the laser stability should satisfy the following expression.

$$\frac{N_x}{N_{Tm}}=\frac{(1+r_{HT}\theta)^2N_{Tm}^2-B^2}{\left[2B-2N_{Tm}(1-r_{HT}\theta)\right](\theta-1)N_{Tm}} \tag{3}$$

$$B=\left(1+r_{HT}\theta\right)N_{Tm}-2\left(\theta-1\right)\frac{\frac{\delta}{\sigma l}+f_lN_{Ho}}{f_u+f_l} \tag{4}$$

where δ is single pass loss factor, l is the crystal production, θ is energy transfer coefficients of Tm and Ho, and r_{HT} is the ratio of the concentration of Ho and Tm. Under the steady work condition, expression (2) should be equal to expression (3). After reorganizing, the equation can be obtained as following.

$$\left(\frac{C^2}{4}+a_2C+a_1^2\right)P_1^2-C^2P_2^2+2CP_2P_3-P_3^2=0 \quad (5)$$

According to the theoretical analysis above, the relationship between P_L and P_p can be obtained, as the red curve shown in Fig.2 (a). The black curve presents the experimental relationship between the pumping power and the output power.

Experimentation

The Cr, Tm, Ho doping concentrations of the CTH: YAG crystal used in the experiment are 0.85%, 5.9% and 0.36 % respectively, and the crystal has 4mm diameter and 1mm thickness. The front surface of the crystal is coated with anti-reflection film at wavelength 785nm (T>99%) and high reflection film at wavelength 2.09um (R>99%). The output surface of the crystal is coated with high reflection film at wavelength 785nm (R>93%) and with 1% transmittance film at 2.09um. Under the 785nm LD pumping condition, the experimental absorption coefficient of the crystal is measured 4.3 cm^{-1}. Taking the output surface reflection into account, 1mm thick CTH: YAG crystal absorption rate is about 56%. The experimental setup is shown in Fig.1, which mainly includes a semiconductor laser, focusing system, micro-chip crystal, cooper heat sink, and the infrared filters.

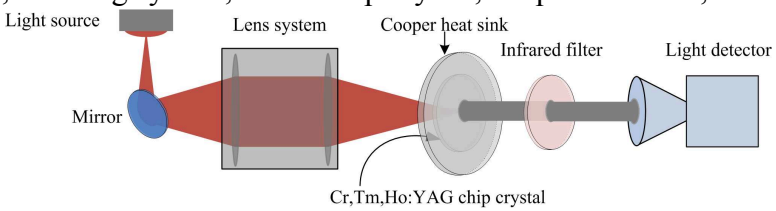

Fig. 1 Sketch of the CTH: YAG micro-chip laser setup

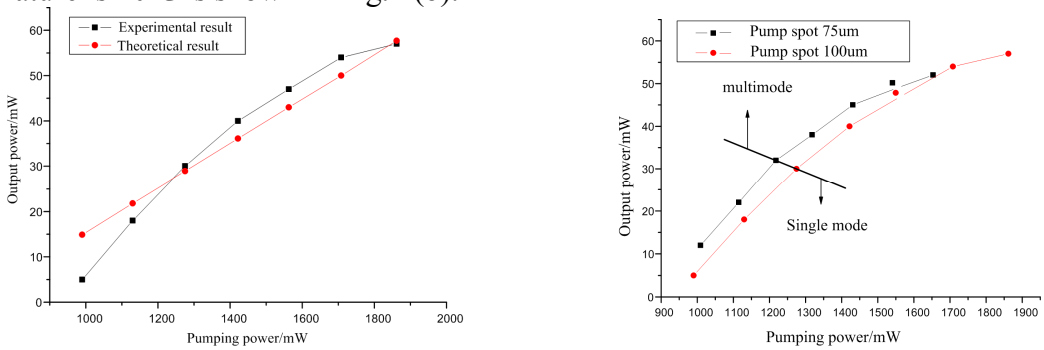
Experimental used pumping maximum power at 785nm is 1.9W, and the light-emitting section is 100um, during which 1:1 and 4:3 focusing systems are used for focusing and the corresponding focused beam diameters is 100um and 75um respectively. Crystal is fixed on the cooper heat sink which is temporal controlled between 10 ℃ and 20 ℃ by a thermoelectric cooler. The infrared filters are used to filter the pump light which is not absorbed. The filter has a high absorption coefficient (T <1%) when the wavelength is shorter than 1um and a high transmittance coefficient (T~90%) when the wavelength is around 2um. A power meter is used to measure the laser output power. The output characteristic curve of the microchip laser at different pumping beam spots when the temperature is 10℃ is shown in Fig.2 (b).



(a) The pumping and the output power (b) Output properties with different beam spots

Fig.2. The theoretical and experimental results

Using a con-focal scanning interferometer, the single-frequency region and multi-longitudinal mode region of the laser are discovered. When the pumping beam spot diameter is 75um, the maximum single-frequency output power is 32mW. When the pumping beam spot diameter is 100um, the maximum output power of the single frequency is 30mW. Correspondingly, the optical to optical conversion slope efficiency is 6.8% and 6% respectively.

Conclusion

In this manuscript, the relationship between the output optical power and 785nm LD-pumped power is obtained by theoretical calculating based on the pumping functions. Then, experimentation is doing to testify the calculating results. The experimental results fit well with the theoretical results and the maximum single-mode output optical power at 2.09μm of the Cr, Tm, Ho: YAG microchip laser is 32 mW .

Keywords: Near Space Airship; Flexible Material; Tear Damage; Space Environment; Multiple Mechanisms Coupling

Abstract. Near space airship increasingly becomes a research hotspot with its inclusive potential military and civilian values. It is necessary to consider single and multiple-coupling space environment effects on evaluating envelope tearing damage mechanisms. The basic characteristics of the space environment and the complexity of tear damage mechanism are introduced, and this presentation also summarizes the research status of the tear damage mechanical mechanism and damage properties under the influence of the multiple space environment factors of high-performance airship envelope. Besides, the main existing problems and prospect in tear damage characterization under real working condition are discussed. The study provides some technical support for high-performance and protecting tearing damage design on airship envelope.

Introduction

With the development of envelope material and solar energy technology, the current ongoing near space airship (floating on the height of 20~30km) projects are practical [1]. many countries such as America, Japan, German, Korea are engaged in studying near space airship. But thermo, temperature, pressure, ozone, UV and other stratospheric environment make it easy to be damaged. Micro cracks or micro holes go expansion, and the result is destruction of envelope material [2].

Considering tear damage mechanical properties, airship envelope material can be seen similar to textile yarn bundle and laminated or coating composite. Combined with flight tests and ground environment chamber simulation tests, there are many researches on macro mechanicals, fatigue life and other aspects to explore the effects of space environment on envelope material [3]. More and more researchers put emphases on micromechanics properties of envelope to reveal its tear failure mechanism under multiple coupling mechanisms and predict fatigue life, which focuses on mesoconstituents of flexibilities and micromechanics characterization and simulation.

Complexities of Airship Envelope Material Tear Damage

Flexible composite material of near space airship envelope is flexible coated fabric or laminated fabric [4]. Its internal reinforced fabric bearing layer and other function layers are combined by coating or laminating adhesive process. Due to fabric bearing layer is one of plain or twill weave, friction and slippage phenomenon occurs when the warp and the weft fiber bundle interact under loading, making its mechanics more complex than other plain or twill weave. In addition, since adhesives substrate plays the role of attaching and bridging, to some extent, function layers elastic-plastic deformation pins down the deformation of bearing layer stretching and bending. Twisted and pre-invaded gum warp and weft yarn bundles add the adhesives friction, making its deformation more complex. From the perspective of meso-tests, it is observed that, yarn bundles fracture caused envelope damage and tearing; the crack tip of tearing appears greater plastic deformation zone than continuum fracture in the course of tearing. It is necessary to take account of such factors as stretch, compression, bending deformation, fracture, friction among layers, substrate crack, benumbing and layered etc. to explore tear mechanism.

Multiple coupling environments in stratosphere make it fatigue and aging; furthermore all constituents go bad and broke one by one. Usually, single or some complex environment not the real space, but the ground simulation tests were adopted to study environment effects on airship envelope material. The differences between simulation environment and real environment add difficulties to analyze its damage and tear. Meanwhile, there are few literatures studying the law of space environment influence on envelope such as surface corrosion, and further researching on failure damage law. However, available information shows that envelope surface deflate, quality impairments, the size and structure local damage because of the vacuum of space environment (≤1.33 mPa) [5]. Affected by ultraviolet ozone factors, high performance yarn bundle presents photolysis; surface morphology change; optical properties; bearing capacity reducing; accelerates aging, degradation and low temperature embrittlement under high and low temperature alternating.

Researches on Mechanical Characteristics of Flexible Material Tear

The particularity of airship envelope molding process and its self-structure makes tear and damage fracture main failure of space airship. Research shows that when the inside and outside overpressure gap reaches certain value, initial defects and micro-cracks begin to expand slowly [6]. Also, it occur that local fiber bundle breakage, matrix cracking and interfacial failure, fiber bundle slippage and reposition in crack tip stress concentration areas, resulting in stress concentration triangle-zone with initial crack damage. In this case, the initial defects and micro-crack stop going spread once overpressure payloads decrease. If the payloads are up to critical value, random crack with a certain shape will expand quickly leading the tear damage of fiber bundles. Initial defects and cracks enlarge dramatically and damage because of pressure resulting from bad working conditions and high-low temperature alternates in a short time. So studies on mechanism of tearing envelope material would lay foundation for optimization of envelope material formation, function design, enhancing its strength and structure layout under complex loads.

The popular ideal fabric reinforced substrate material, PBO, Kevlar and Vectran of near space airship, with the characterization of high strength, light weight, low elongation, corrosion resistance and anti-aging, are weaved as bearing layer of airship envelope. Tear damage strength of textile material is related to singe fiber bundle strength, woven process and substrate features. Although the fiber bundles broke one by one, the crack tip stress spreads out by adjacent bundles shearing, making fiber around the fracture withstanding tensile stress. The number of fiber bundles bearing tensile stress is related to the fiber bundle pitch, the curvature of the fiber, braided angle, cross-sectional shape, fiber twists and other parameters, affecting the tear strength of fabric. Envelope material coating layer (or function layer) not only acts adhesive, air resistance, abrasion resistance and anti-aging but also has great impact on shear properties, limiting the movement of the fiber bundle node, thus affecting tear damage of envelope material.

Tear damage of near space airship envelope is complex. As the stress of envelope material increase to certain value, fiber bundles appear different scales damage in ontology micro-scale and initial crack and defects gradually enlarge. When the stress exceeds the critical breaking strength or elongation, yarn bundle begin to break in succession and slides and relocates in the stress concentration zone, forming triangle stress concentration zone with initial crack and resulting in interface failure and breakage of substrate. With the increase of stress loads, fibers in crack tip zone continuously go fracture. materials go through micro-meso-macro damage, finally get rupture completely. The tearing modal is influenced by components material, coating process, woven forms, interface features and associated with initial defects, crack orientation, environment payloads etc., making it difficult to explore exact mechanism of tear modal.

Envelope structure meso-mechanics can help pursue further study of tear damage mechanism. Scholars develop geometry and mechanical model to investigate envelope mesostructure. Characterization involves in cross-section shape changes and fiber bundle/substrate interface geometry. Researches have presented mosaic, bending and bridging of constituents' structure properties, taking in account fluctuation and pitch in the fiber other factors, to calculate stress and analyze cumulative failure behavioral characteristics. On basis of strain homogenization theory,

effective elastic modulus and thermal expansion coefficient get focus Zhang Yitong etc. put forward fabric oblique heterosexual constitutive equations, studying oblique yarn constitutive behavior under tensile formation. Zhang Chao etc. set method to predict and analyze elastic properties of two-dimensional biaxial woven composite materials based on meso-analysis and volume average method. These efforts provide a valuable reference for studies of coated woven geometric model and mechanical model, but all existing models are mainly applied to predict the elastic properties and strength, not suit for accurate description of envelope tearing.

Studies have shown that overpressure gap induced by sunlight on airship balloon in short time, cause original crack or defects expand and destroy abruptly [7]. Research on airship coating woven tear propagation under biaxial stress and complicated curvature was made. Stress field of envelope material will redistribute randomly. a majority of studies of envelope material tear damage still remain in test observation and qualitative analysis level. However, some researches use material energy function based on random statistical model to express these complicated variation and build crack propagation moldal to predict most likely path of crack propagation via system energy changes. Meanwhile environment adds complexity on material constituents and mechanic parameters. The current on-going projects on coated envelope tear propagation simulation are relatively few. Finite element analysis software usually adopts “life and death cell” method for fiber fracture failure simulation in dynamic simulation. Up to now, there isn’t some method applied to simulate tear propagation under any complex condition to guarantee appropriate accuracy.

Tear Damage Failure Characteristics in Space Environment

The particularity and complexity of space environment make envelope material inevitably bear multiple coupling loads (micro-gravity, high vacuum, ultra high-low alternates, thermal stress fatigue, light aging, ozone, ultraviolet radiation aging, plasma impact etc.) under which material prone to aging, degradation causing envelope and its constituent physical, chemical and mechanical changes and even complete failure. Seldom research on single or multiple effects on envelope material is in progress. Most of researches focus on envelope constituents such as high performance fibers, adhesive substrate layer, and functional layer etc. What’s worse, fewer researchers did tests on multiple coupling loads.. Bending fatigue mechanical properties of fiber bundle under light heat and UV effect got research.

Tamargor etc. employed gravimetric analysis to explore the thermal decomposition characteristics of high performance fiber PBO and used DTG curve to study thermal stability of blend fabric Kevlar/Nomex.. Envelope material appears light aging when working under light, affecting the fiber fracture strength, modulus, breaking elongation, the material composition, surface structure and so on. Day M , Arrieta C etc. carried on outdoor sunlight aging test, researching on light aging strength retention of Nomex and Kevalr49, and discover that illumination damage material mechanics from outside to inside. High strength fiber Kevlar is eager to degradation of the mechanical properties under ultraviolet light. For light and thermal, until now, multiple mechanism experiments only including light aging first and heat aging, heat aging first and light aging have been done, demonstrating that fiber resistance is worse than that in single mechanism environment. Currently, projects on high performance envelope environment resistance are just ongoing. Beihang University, Harbin Institute of Technology, Donghua University has explored some ground simulation environment tests. However, there are many single mechanism environment researches, rather than multiple coupling tests so the effect of multiple coupling environment on high performance envelope tear damage and tear propagation isn’t still evident. Predicts of envelope material tear damage and macro strength are unclear and not quantified. The ongoing application on engineering usually refers to initial extension strength of crack on basis of fracture theory.. Meanwhile, near space environment full of complexity and variation cause envelope tear evolution more unclear.

Prospects

Currently, most of researches on envelope material tear and damage put emphasis on uniaxial / biaxial tensile mechanics. Actually, tensile stress fatigue and bending fatigue further affect tear damage properties under overpressure condition. As usual, the method of continuum macroscopic fracture mechanics and damage mechanics is used to deliver characterizations of envelope tear damage. But, discreteness of bearing fiber and randomness of fracture fiber cause large errors in studying envelope properties by macroscopic fracture mechanics.

On the other hand, new ground multi-mechanism coupling environment simulation test instruments should be developed, making ground environment simulation test equipment to simulate single mechanism or multiple coupling mechanisms. It is valid to verify the tear damage of envelope material in real space environment coupling of multiple factors by means of ground simulation test. During airship envelope works in the space, airbag buoyancy gas such as helium, hydrogen penetrates envelope material through crack. Whereas, the leakage of buoyancy gas accelerate the propagation of initial defects and crack, further affecting fatigue life and stratospheric airship envelope performance. Therefore, in high overpressure condition, failure of airship envelope material must consider the extension response of micro crack or micro holes.

Conclusion

To guarantee airship envelope long-term use and maintain high performance under complex space environment, Studies on envelope material tearing damage should consider thermal stress fatigue caused by temperature variation, thermal cycle, ozone aging, ultraviolet radiation, natural light and so on. Single mechanism and multiple mechanisms should be tested or simulated respectively to explain its function. The damage of envelope material is not a simple plus of several kinds of damage, but a complex coupling of different environment which decide material life.

Except for studies on single mechanism on envelope, as much as possible space environment factors (multiple coupling and interaction of different mechanisms) should be added to develop modal and evolution of envelope damage. Ground environment simulation instruments and device should be set to simulate space environment as real as possible to explore tear damage and accurate characterization methods under the influence of environmental factors.

Keywords: 1-3 piezocomposite, PZT/epoxy, PZT Volume Fraction

Abstract. PZT672/epoxy 1-3 piezoelectric composites were fabricated by the cut-filling method. The parameters of PZT672/epoxy 1-3 piezoelectric composites varying with different PZT volume fractions have been measured and compared with theoretical values. The results show a good match between theoretical values and measurements. The authors conclude the regular of the properties of composites varying with PZT volume fraction.

Introduction

Piezocomposite is composed by piezoelectric ceramic and polymer phase according to a certain way connected and certain volume or weight ratio[1]. It is a new type material which can greatly improve the piezoelectric properties. 1-3 piezocomposite is the major type of piezocomposites, It consists of the one dimensional connected thin piezoelectric ceramic column paralleled arrangement in the three dimensional connected polymer[2]. It is extensive researched and applied in recent years. 1-3 piezocomposite has the following advantages[3]: low impedance, easier to match with water or human tissue, low Q value, small transverse electromechanical coupling coefficient, good flexibility and high hydrostatic pressure piezoelectric constant. It also can be made into special shape. In addition, it is easier to improve the properties by changing PZT or polymer volume fraction. In this paper, the regular of properties of composites varying with PZT volume fraction will be researched.

Theoretical Derivation of The Properties of 1-3 Piezocomposite

1-3 piezocomposite usually works in thickness vibration patterns, according to the characteristics of thickness vibration mode[4] the properties of 1-3 PZT/epoxy piezocomposite are derivated by e piezoelectric equation[1] and force-electricity boundary conditions. By the constitutive equations of materials[5]:

Piezoelectric phase (1):

$$\begin{cases} S_1^c = \left(s_{11}^{Ec} + s_{12}^{Ec}\right) T_1^c + s_{13}^{Ec} T_3^c + d_{31} E_3^c \\ S_3^c = 2 s_{13}^{E} T_1^c + s_{33}^{E} T_3^c + d_{33} E_3^c \\ D_3^c = 2 d_{31} T_1^c + d_{33} T_3^c + \varepsilon_{33} E_3^c \end{cases} \tag{1}$$

Polymer phase (2):

$$\begin{cases} S_1^p = \left(s_{11}^{Ep} + s_{12}^{Ep}\right) T_1^p + s_{12}^{Ep} T_3^p \\ S_3^p = 2 s_{12}^{Ep} T_1^p + s_{11}^{Ep} T_3^p \\ D_3^p = \varepsilon_{11}^p E_3^p \end{cases} \tag{2}$$

According to the working state of 1-3 piezocomposite, introducing the corresponding physical boundary conditions[6] as Eq. 3:

$$\begin{cases} S_3^c = S_3^p = \overline{S_3} & \overline{S_1} = vS_1^c + (1-v)S_1^p = 0 \\ E_3^c = E_3^p = \overline{E_3} & \overline{T_3} = vT_3^c + (1-v)T_3^p \\ T_1^c = T_1^p = \overline{T_1} & \overline{D_3} = vD_3^c + (1-v)D_3^p \end{cases} \tag{3}$$

Bring Eq. 3 into Eq. 1 and Eq. 2, available elastic constants $\bar{c}_{33}^{E}\ \bar{c}_{33}^{D}$, piezoelectric constant $\bar{e}_{33}\ \bar{h}_{33}$, dielectric constant $\bar{\varepsilon}_{33}^{s}$, piezoelectric isolation rate $\bar{\beta}_{33}^{s}$, piezocomposite density $\bar{\rho}$, thickness electromechanical coupling coefficient $\bar{K}_t$, acoustic impedance $\bar{Z}$ and compressional wave velocity $\bar{v}_t$ expression[6] of 1-3 piezocomposite are simplified as follows Eq. 4 - 13:

$$\bar{c}_{33}^{E} = v\left[c_{33}^{Ec} - 2(1-v)\left(c_{13}^{Ec} - c_{12}^{Ep}\right)^2 \Big/ \left(v\left(c_{11}^{Ep} + c_{12}^{Ep}\right) + (1-v)\left(c_{11}^{Ec} + c_{12}^{Ec}\right)\right)\right] + (1-v)c_{11}^{c} \tag{4}$$

$$\bar{e}_{33} = v\left[e_{33}^{c} - 2(1-v)e_{31}^{c}\left(c_{13}^{Ec} - c_{12}^{p}\right) \Big/ \left(v\left(c_{11}^{p} + c_{12}^{p}\right) + (1-v)\left(c_{11}^{Ec} + c_{12}^{Ec}\right)\right)\right] + (1-v)\varepsilon_{11}^{p} \tag{5}$$

$$\bar{\varepsilon}_{33}^{s} = v\left[\varepsilon_{33}^{Ec} + \left(2(1-v)\left(e_{31}^{c}\right)^2\right) \Big/ \left(v\left(c_{11}^{p} + c_{12}^{p}\right) + (1-v)\left(c_{11}^{Ec} + c_{12}^{Ec}\right)\right)\right] + (1-v)\varepsilon_{11}^{p} \tag{6}$$

$$\bar{c}_{33}^{D} = \bar{c}_{33}^{E} + \bar{e}_{33}^{2} \Big/ \bar{\varepsilon}_{33}^{s} \tag{7}$$

$$\bar{h}_{33} = \bar{e}_{33} \Big/ \bar{e}_{33} \tag{8}$$

$$\bar{\beta}_{33}^{s} = 1 \Big/ \bar{\varepsilon}_{33}^{s} \tag{9}$$

$$\bar{\rho} = v\rho^{c} + (1-v)\rho^{p} \tag{10}$$

$$\bar{K}_t = \bar{h}_{33} \Big/ \left(\bar{c}_{33}^{D}\bar{\beta}_{33}^{s}\right)^{1/2} = \bar{e}_{33} \Big/ \left(\bar{c}_{33}^{D}\bar{\varepsilon}_{33}^{s}\right)^{1/2} \tag{11}$$

$$\bar{v}_t = \left(\bar{c}_{33}^{D} \Big/ \bar{\rho}\right)^{1/2} v \tag{12}$$

$$\bar{Z} = \left(\bar{c}_{33}^{D}\bar{\rho}\right)^{1/2} \tag{13}$$

Series of the above equations, the superscript "-" "c" and "p" express respectively composites, ceramic and polymer material parameters, "t" and "v" express respectively the thickness of piezocomposite and PZT volume fraction.

Fabrication

1-3 piezocomposite is fabricated by the cut-filling method. PZT672(Zhejiang Jiakang Electronics Co, Ltd) is used as piezoelectric function component and epoxy618(China National Chemical Corporation) is used as passive component. PZT672 is a new type of piezoelectric ceramic. It is the favorable material used on sensitive element of ultrasonic transducer. Its detailed properties are shown in Table 1.

Table 1 Properties of PZT672

Material	PZT-672
Q value	247
Electro-mechanical coupling factor K_t	0.48
The quasi-static capacitanceCp(pF)	1754
DepletionD(mU）	15.5
Relative dielectric constant $\bar{\varepsilon}_{33}$	3818
Piezoelectric constant d_{33}（pC/N）	550

PZT672 were cut by automatic scribing machine(DISCO DAD321). Different 1-3 piezocomposite samples were fabricated by changing steps. The PZT volume fractions of 1-3 piezocomposite are varying from 54.76% to 77.76%. The cutting parameters were list in Table 2. Epoxy 618, curing

agent and flexibilizer were mixed by the proportion of 10:1:1. Poured into PZT672 skeleton, solidified for 12 hours in the room temperature. And then the piezocomposite samples were polished with grinding machine(PowerPro3000). The thickness was set to be 0.66 mm. Due to the limitation of precision of the grinding machine, the thickness of samples had a certain difference. The thickness of each sample is shown in Table 2. Finally the electrode was fabricated with magnetron sputtering apparatus(Kurt J.Lasker Inc.). At this point1-3 piezocomposite samples were fabricated completely.

Table 2 Data of fabricated samples

Sample number	Step t(um)	Slit width a (um)	Column width b（um）	PZT Volume fraction v(%)	Thickness h（mm）
1#	250	65	185	54.76	0.65
2#	350	65	285	61.36	0.63

6#	550	65	485	77.76	0.69

Properties Measured

The properties of six samples are measured with impedance analyzer (Agilent4294A). The results are shown in Table 4. The electromechanical coupling coefficient is calculated by Eq. 14. The relative dielectric constant is calculated by Eq. 15. The sound velocityis calculated by Eq. 16. The acoustic impedance is calculated by Eq. 17. In Eq. 14 to 17, f_p expresses parallel resonant frequency.

$$K_t = \sqrt{\pi/2 * f_s/f_p * \tan\left(\pi/2 * (f_p - f_s)/f_p\right)} \tag{14}$$

$$\bar{\varepsilon}_{33} = v\varepsilon_{33}^c + (1-v)\varepsilon_{33}^p \tag{15}$$

$$v_t^D = 2 f_p t \tag{16}$$

$$\bar{Z} = \bar{\rho} v_t^D \tag{17}$$

Results and Discussions

a. PZT volume fraction effects on electromechanical coupling coefficient K_t

Electromechanical coupling coefficient is a physical quantity which represents the conversion capability of mechanical energy and electric energy of piezoelectrics. It is one of the important parameters of piezoelectric material. On the condition of piezoelectric effect, the electromechanical coupling coefficient is equal to the ratio of transformed electrical energy to the mechanical energy. The curve of calculated K_t has been shown in Fig.1and it is compared with measurement curve. Fig. 1 shows that while PZT volume fraction increasing from 40% to 100% the theoretical value slowly increases and reaches the maximum in about 70%, and then slowly falls. In this region, the measurement value is slightly smaller than the theoretical value and they have the same trend, and the deviation is less than 5.8%. Both are far greater than the electromechanical coupling coefficient of single PZT 0.48. The reason for the deviation is that each piezoelectric column is approximated slender column. Its length is much greater than width in theoretical calculation. But the piezoelectric

column cannot achieve the approximate conditions actually. The vibration modal is not entirely the longitudinal vibration of slender column. Therefore its electromechanical coupling coefficient measured is slightly lower than theoretical value.

b. PZT volume fraction effects on the relative dielectric constant $\bar{\varepsilon}_{33}^{s}$

The curves of calculated $\bar{\varepsilon}_{33}^{s}$ changing with PZT volume fraction and the measurement results have been shown in Fig. 2. While PZT volume fraction increasing from 40% to 100% the theoretical value increases linearly. Meanwhile, the measured value also increases linearly and it has the same trend as theoretical value. Measured value is lower than the theoretical value, and the deviation is about 19.9%. The deviation is mainly caused by the high temperature when high energy Ag ions deposited onto the surface of sample in the process of sputtering. It makes the samples at high temperature and the piezoelectric ceramic appears partial depolarization effect. Therefore it makes the relative dielectric constant value lower than expected value.

c. PZT volume fraction effects on the acoustic impedance $\bar{Z}$

Sound velocity is the speed of sound wave propagation in elastic medium. Using Matlab to calculate v_t^D in Eq. 12 and draw the curve changing with PZT volume fraction, and compared it with measurement curve which has been shown in Fig. 3. As we can see, the theoretical value increases slowly with PZT volume fraction varying from 40% to 90%. And it sharply increases when the PZT volume fraction higher than 90%. In the same time, the measured value is close to theoretical value with the same trend, and the deviation is less than 4.41%.

Acoustic impedance is a physical quantity introduced when analyzing acoustics system with lumped parameter. Using Mtalab to calculate $\bar{Z}$ in Eq. 13 and draw the curve changing with PZT volume fraction, and compared it with the measurement curve. The comparison is shown in Fig. 4. The PZT volume fraction varying from 40% to 100% the acoustic impedance also increases linearly. And the measured value is close to theoretical value with consistent trend, and the deviation is no more than 4.38%.

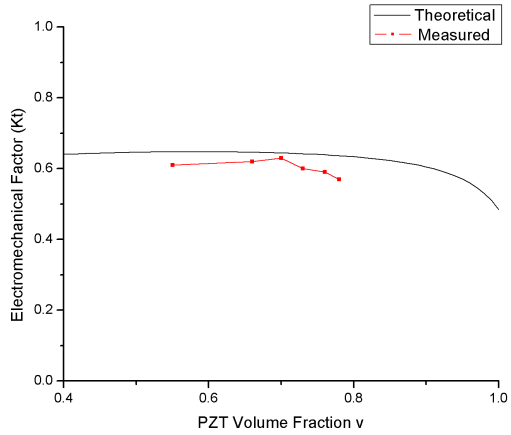

Fig. 1 Electromechanical coupling coefficient

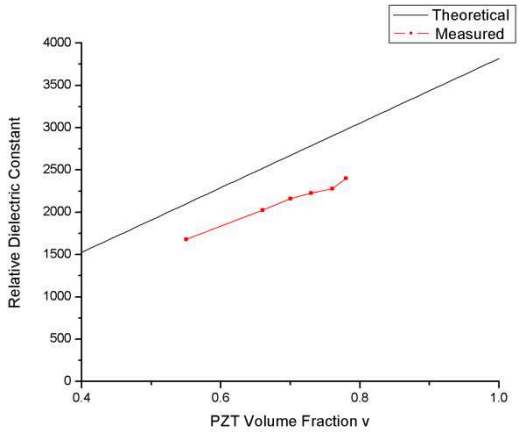

Fig. 2 Relative dielectric constant

By contrasting and discussing the results, measured value is close to theoretical value with consistent trend and also exists a certain deviation. The causes of the deviation are also caused by the following reasons. First, the grinding deviation of the samples can affect the measured deviation. Second, the assumptions of theoretical derivation are the simplify of analytical substance. The third reason is that the theoretical values of properties of PZT672 and epoxy are derived from reference, and a certain difference exists between the theoretical value and the actual value.

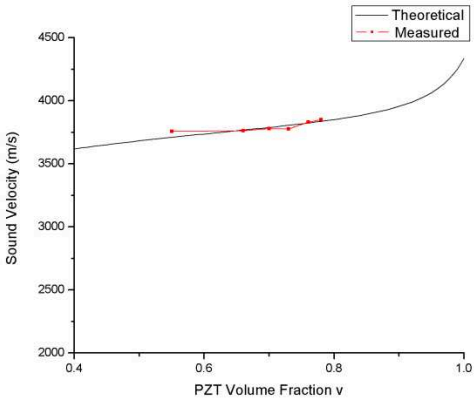

Fig. 3 Sound velocity

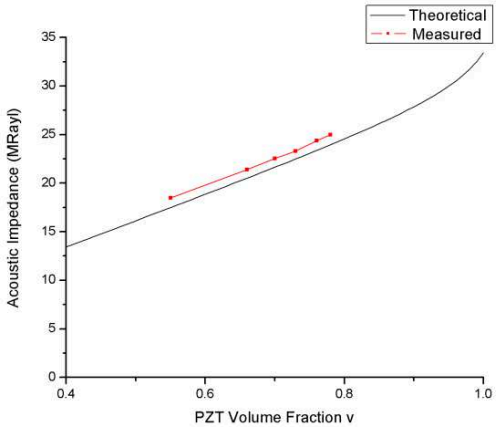

Fig. 4 Acoustic impedance

Conclusions

In this paper, the performance parameters of 1-3 piezocomposite are derived theoretically. Using Matlab to calculate performance parameters and draw the curve changing with PZT volume fraction. Different PZT volume fraction samples are fabricated, and compared the measured value with theoretical value. All the comparison results show that the measured value and the theoretical value have the same trend while the PZT volume fraction varying 54.76% to 77.76%. The electromechanical coupling coefficient reaches the maximum in about 70% volume fraction. The results of this paper provide the reference to choose the piezocomposite PZT volume fraction in practical application.

Keywords: Glasses; Phosphors; Luminescence; White-light-emitting

Abstract. $Ce^{3+}/Tb^{3+}/Sm^{3+}$ co-doped phosphate glasses were prepared by melt quenching method. The full colors including blue, green and reddish orange emitting were observed simultaneously in the photoluminescent spectra of the glasses at 377 nm excitation, and the combination of these three emitting allows the realization of white light emitting. The CIE chromaticity coordinate (x=0.339, y=0.331) of the emission from the glass is close to the standard white-light illumination (0.333, 0.333). Moreover, the tunable luminescent color and chromaticity parameters could be realized by varying the content of Tb_4O_7 dopant in the glass composition, which is promising fluorescent materials for white light emitting diodes applications.

Introduction

In recent decades, the luminous materials doped with rare earth and transition ions have been studied for color display, temperature sensor, fluorescence labeling, white light simulation [1–5] and so on.

In view of energy and environment problems, it is absolutely necessary to develop pollution-free, cheap, highly efficient white-light-emitting (WLE) materials. It has been found that the

homogenization of the emission in the single phosphor is better compared to that in the mixed phosphors. The product cost of the single phosphor is also lower than that of the mixed phosphors. Thus, it is most valuable to study the single and novel phosphor. In response to these considerable challenges, luminescence glasses could be applied as good potential candidate for developing LEDs devices. Nowadays, some studies have been focused on the possible applications of rare earth ions doped glasses in the fabrication of white LEDs [6−7]. Liang et al. studied the luminescence properties of Tb^{3+}/Sm^{3+} co-doped B_2O_3 – Al_2O_3 – SrO system glasses and glass ceramics [8]. Song et al reported $Tm^{3+}/Tb^{3+}/Mn^{2+}$ co-doped phosphate glass ceramic for enhanced white-light-emitting material [9]. At ultraviolet light excitation, the emission efficiency of the visible light is higher. At ~360 nm light excitation, the materials doped with Tm^{3+}, Tb^{3+}, and Mn^{2+} ions were discovered to be of the blue, green and red phosphors [10−11], respectively. To our best knowledge, no researches on the WLE of $Ce^{3+}/Tb^{3+}/Sm^{3+}$ co-doped strontium zinc phosphate glass have been reported. Hence, in this work, $Ce^{3+}/Tb^{3+}/Sm^{3+}$ co-doped SrO – ZnO – P_2O_5 glass samples were prepared in order to realize the white light emitting and tunable luminescent color.

Experimental procedure

Powders of analytical reagent grade, comprising SrCO3, ZnO, NH4H2PO4 (≥99.5%) and high purity Ce(NO3)3 6H2O, Tb4O7 and Sm2O3 (≥99.99%), were used as the starting materials. The detailed compositions of the glasses are listed in Table 1. The glass batch was melted in a corundum crucible in air at 1230°C for 60 min. Glass melts were poured into a preheated copper mold for quenching. The glass samples were annealed at 480 °C for 2 h to release thermal stress and then cooled to room temperature. For further optical characterization, the bottoms of glass samples were polished carefully to form a mirror surface. The emission and excitation spectra were recorded on FL3-TCSPC fluorescent spectrometer (Horiba Jobin Yvon, France), using Xenon lamp as the

excitation source. All measurements were performed at room temperature. The chromaticity coordinates(x, y) were calculated based on the photoluminescent spectra by using software.

Table1. Composition of the glasses with CeO_2, Tb_4O_7 and Sm_2O_3 added (mol %)

Glass no.	SrO	ZnO	P_2O_5	CeO_2	Tb_4O_7	Sm_2O_3
A	21	42	37	0.1	0	0
B	21	42	37	0	0.125	0
C	21	42	37	0	0	2
D	21	42	37	0.1	0.125	2
E	21	42	37	0.1	0.25	2
F	21	42	37	0.1	0.5	2

H	21	42	37	0.1	1	2

Results and discussions

Fig. 1a shows the emission spectra of glasses A, B and C excited by 377 nm. A wide emission band peaking around 440 nm assigned to the 5d→4f electronic transition of Ce3+ is observed in the photoluminescent spectrum of sample A. For glass B, some characteristic emission occurs from 5D3 (blue) and 5D4 (green) levels to the ground state of Tb3+. The emission bands peaking at 438 and 415 nm are associated with the 5D3→7FJ (J=4, 5) electronic transitions, while the emission lines locating at 620, 582, 545 and 488 nm are due to 5D4→7FJ (J=3, 4, 5, 6) electronic transitions of Tb3+. In the spectrum of sample C, there are three emission lines peaking at 565, 605 and 648 nm originated from 4G5/2→6H5/2, 4G5/2→6H7/2 and 4G5/2→6H9/2 electronic transitions of Sm3+, respectively [13]. Fig. 1b depicts the excitation spectra of glasses A, B and C monitored at 444, 545 and 605 nm, respectively. There is a wide band peaking at 380 nm in the excitation spectrum of sample A. The excitation spectrum of sample B consists of four bands peaking at 350, 369, 377 and 484 nm and they correspond to the electronic transitions of Tb3+ ions from ground state 7F6 to excited states 5D2, 5D3, 5D4 and other higher 4f excited levels, respectively [14]. Three excitation bands peaking at 345, 362 and 375 nm corresponding to the 6H5/2→4K17/2, 6H5/2→4D3/2 and 6H5/2→6P7/2 transitions of Sm3+ respectively are included in the excitation spectra of sample C [15].

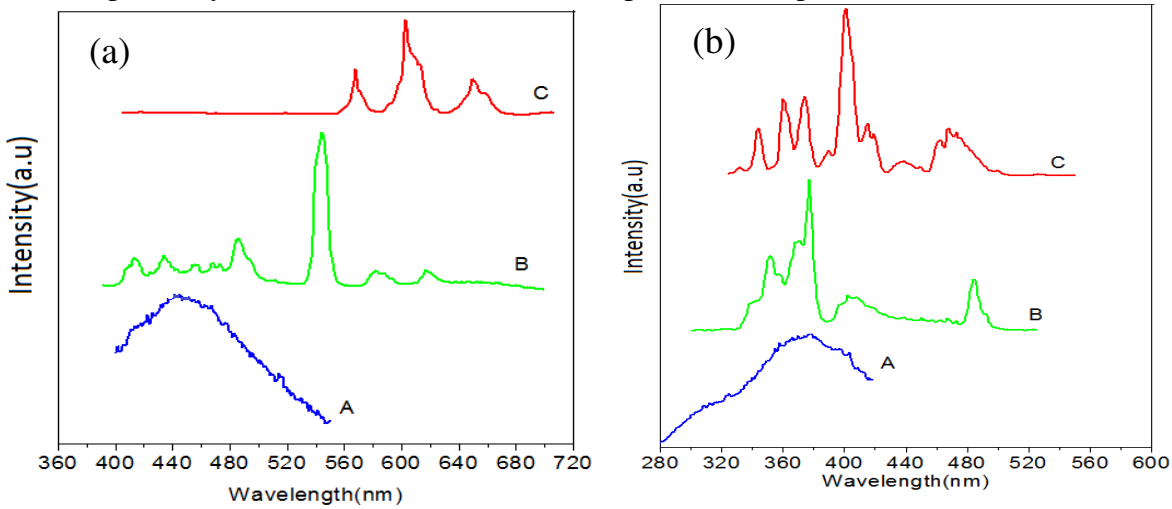

Fig. 1 Emission spectra of glasses A, B and C excited by 377 nm (a) and excitation spectra of glasses A, B and C monitored at 444, 545 and 605 nm (b)

Fig. 2a gives the emission spectra for co-doped glasses D, E, F, G and H excited by 377 nm. For all glass samples, the emission bands peaking at about 437 and 415 nm are ascribed to 5D3→7FJ (J=4, 5) transitions of Tb3+, and the emission bands locating at about 620, 585, 544 and 488 nm correspond to 5D4→7FJ (J=3, 4, 5, 6) transitions of Tb3+, as has been mentioned above [16]. The weak emission

band peaking at 440 nm is assigned to the 5d→4f electronic transition of Ce3+. Besides, the emission lines peaking at 565, 605 and 645 nm originate from 4G5/2→6H5/2, 4G5/2→6H7/2 and 4G5/2→6H9/2 electronic transitions of Sm3+, respectively. The positions of emission peaks are nearly the same for the samples D, E, F and G. Blue, green and reddish orange emission bands are observed in the emission spectra of these four glasses. Spectral comparison in Fig. 2a indicates that the concentration of Tb3+ has an important effect on the luminescence properties of glasses with a certain concentration of Ce3+ and Sm3+. The glass with a higher concentration of Tb3+ exhibits much enhanced green light (544 and 490 nm) and blue light (437 and 415 nm) due to the 5D4 and 5D3 emission of Tb3+. In other words, the increase in the Tb3+ concentration leads to the enhancement of 5D4 and 5D3 emission of Tb3+. With further increase of Tb3+ concentration up to 1mol%Tb4O7 (glass H), the new emission bands locating at about 585 and 620 nm corresponding to 5D4→7FJ (J=3, 4) transitions of Tb3+ occur. Meanwhile, the typical emission lines peaking at 565, 605 and 645 nm originated from 4G5/2→6HJ/2 (J=5, 7, 9) electronic transitions of Sm3+ disappear shown in Fig.2a. A typical excitation spectrum of glass sample G monitored at 444, 545 and 605 nm, respectively, as shown in Fig. 2b. The excitation band monitored at 444 nm is assigned to the 5d→4f electronic transition of Ce3+ and the peak position is located at 377 nm around. In addition, the spectrum monitored at 545 nm consists of five bands peaking at 352, 369, 377 and 484 nm and they correspond to the electronic transitions of Tb3+ ions from ground state 7F6 to excited states 5DJ (J=2, 3, 4) and other higher 4f excited levels respectively. Moreover, there are five excitation bands peaking at 345, 362, 374, 401 and 474 nm in the excitation spectrum monitored at 605 nm. These bands are corresponding to the 6H5/2→4K17/2, 6H5/2→4D3/2, 6H5/2→6P7/2, 6H5/2→4K11/2 and 6H5/2→4I13/2 transitions of Sm3+. Efficient excitation of these kinds of Ce/Tb/Sm co-doped glass with ultraviolet radiation is confirmed here and well fits the requirement of W-LEDs.

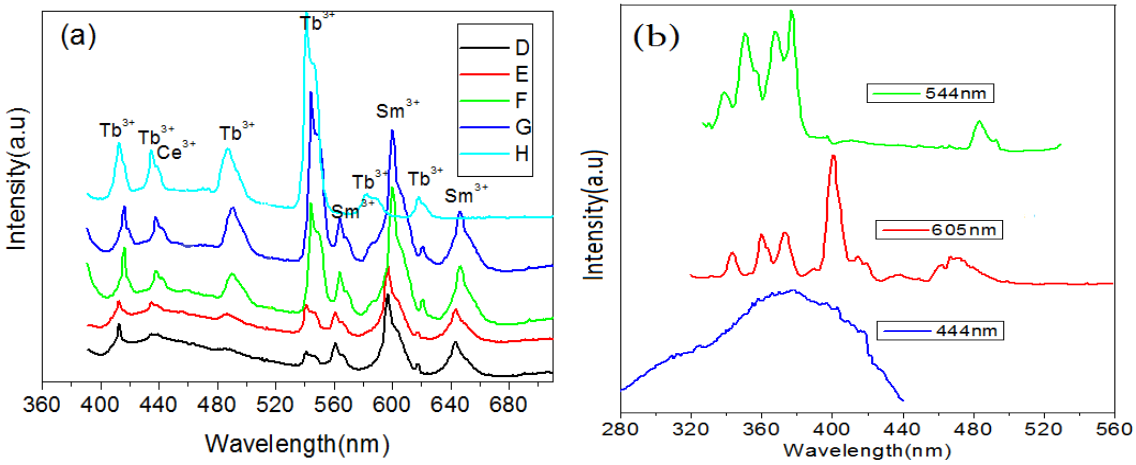

Fig. 2 Emission spectra of glasses D, E, F, G and H excited by 377 nm (a) and a typical excitation spectra of glass G monitored at 444, 544 and 605 nm (b)

The CIE chromaticity diagram for glasses D–H is shown in Fig.3. As seen from Fig.3, at 377 nm excitation, all the co-doped glass samples allow the realization of white light emission mainly due to the mixture of blue, green and red emitting under the same conditions except for glass H. The CIE chromaticity coordinates of the emissions from glasses D-H are (x=0.314, y=0.285), (x=0.316, y=0.292), (x=0.339, y=0.331), (x=0.346, y=0.353) and (x=0.129, y=0.113), respectively. Thus, the luminescent color can be easily altered by varying the content of doped rare earth ions, which realizes the tunable chromaticity parameters and color of these glasses.

Conclusion

Ce3+/Tb3+/Sm3+ co-doped phosphate glasses were prepared by melt quenching method. The full colors including blue, green and reddish orange emitting are observed simultaneously in the emission spectra of the glass samples except for glass sample H, and the combination of these emission bands

allows the realization of white light emitting at 377 nm excitation. Furthermore, the tunable luminescent color and chromaticity parameters could be easily realized by varying Tb4O7 content, which makes the glasses good candidates for WLEDs.

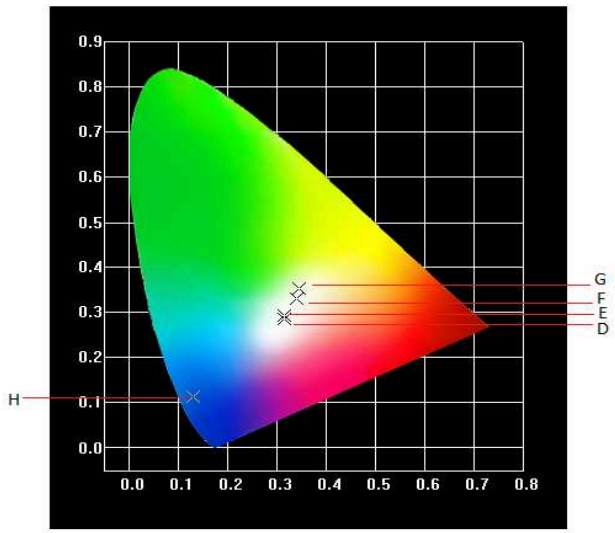

Fig. 3 CIE chromaticity diagram for glasses D–H under 377 nm radiation

Keywords: porous gels, graphene, graphene oxide, adsorption

Abstract. The porous graphene oxide (GO) gels were prepared using the process of aqueous gel precursor freezing, solvent exchange, and ethanol drying technology. The GO sheets were consolidated by PVA and the obtained GO-PVA gel was reduced by glucose to prepare graphene nanosheet-SA (RGO-PVA) gel. GO-PVA and RGO-PVA gels exhibited the ultra-light densities of 10.52 and 11.24 mg/cm^3, respectively. GO-PVA and RGO-PVA can effectively adsorb the liquids. The less the polarity of the liquid was, the more the adsorption for both GO-PVA and RGO-PVA gels was. The equilibrium and the dynamic adsorption of methylene blue dye were also investigated. The maximum adsorption capacities of dye were 571.4mg/g for GO-PVA and 81.0 mg/g for RGO-PVA at 30 ºC.

1. Introduction

The dye-contaminated wastewater is one of the most serious environmental problems, which are harmful to human beings and toxic to microorganisms [1]. Graphene oxide (GO) has proven to be a highly effective absorbent of methylene blue (MB) and can be used to remove MB from aqueous solution at a huge absorption capacity of 714 mg/g [2]. However, GO is hydrophilic and is hard to separate from water. Since GO has the hydrophilic edges and a hydrophobic basal plane, it can be used in the construction of various supramolecular structures. The hydrogen bonding, static or hydrophobic interactions can make the flexible GO sheets form the 3D monoliths. The formation of 3D monoliths can be realized by adding cross-linkers [3]. Poly(vinyl alcohol) was added as a cross-linker to form a pH-sensitive supramolecular hydrogel with 3D network of GO [4]. Hydrogen bonding between GO sheets and PVA chains is important to form the gels. Single-stranded DNA was also found to be a cross-linker for preparing a GO/DNA composite hydrogel, in which π-π interaction was the dominant driving force [5].In this study, monolithic GO gels were prepared using a freezing, solvent exchange (ice-ethanol) and ethanol drying (FSE) method rather than supercritical drying technology. PVA was used to crosslink GO sheets to form a 3D network. Porous and ultra-light GO gels were obtained, and RGO (reduced GO) gels were also prepared by reduction with glucose. The adsorption behavior of solvents and MB dye by graphene-based gels were investigated to know the new adsorbents well.

2. Materials and methods

2.1. Materials

Natural graphite flakes were provided by Qingdao Tianhe Graphite Co., Ltd, China. The reagents (37.5% HCl, 98% H2SO4, 30% H2O2, and 30% NH3) and the analytical grade reagents (NaNO3, KMnO4, glucose, and ethanol) were obtained from Tianjin Jiangtian Chemical Reagent Co. Ltd. in China. The methylene blue (MB) and PVA were provided by Tianjin Benchmark Chemical Reagent Co., Ltd. Soybean oil was purchased from COFCO Northsea Oils & Grains (Tianjin) Co., Ltd, China.

2.2. Preparation of GO

GO was prepared using the modified Hummers' method [6]. Concentrated H2SO4 (46 mL) and NaNO3 (1 g) were added into an anhydrous beaker at 0 ºC (ice bath), followed by the addition of

graphite (2 g). Then KMnO4 (6 g) was added gradually with stirring while the temperature of the mixture was kept below 20 ºC. The mixture was stirred for 2 h in an ice-bath, and the mixtures reacted for another 1 h at 35 ºC. Distilled water (92 mL) was slowly added to the mixture, and then the temperature was kept at 98 ºC for 15 min. The mixture was then further diluted to 280 mL with distilled water and treated with 30% H2O2. The mixture turned bright yellow. The product was centrifuged and washed with diluted HCl solution and then washed with distilled water to remove the acid.

2.3. Preparation of GO-PVA and RGO-PVA gels

PVA (0.0453 g) was dissolved in distilled water (5mL) at 90oC. 20mL GO dispersion (6.8mg/mL) was added into the PVA solution, and the mixture was shaken violently to form a gel. The mixture was placed at room temperature for 24 h for gelatinization. The gels were frozen for 12 h at -10 ºC. Then the yellow gel was washed several times with ethanol and dried.

The GO-PVA gel was reduced following the method of Ma [7]. Ammonia (30 wt%) solution was added to 50 mL distilled water to adjust to pH 10, and then 2 g glucose was dissolved in the solution, followed by the addition of the dry GO-PVA gel. The mixture reacted for 1 h at 95 ºC in a sealed container. The dark RGO-PVA gel was washed respectively with distilled water and ethanol, and then dried at 50 ºC.

2.4. Scanning electron microscopy (SEM).

The fracture surfaces of GO-PVA and RGO-PVA gels were viewed with a Hitachi S-4800 scanning electron microscope.

2.5. X-ray diffraction (XRD)

GO, GO-PVA and RGO-PVA powders were placed in a sample holder for X-ray diffraction (XRD). XRD patterns were recorded in reflection mode in the angular range of 5-30º (2θ), at ambient temperature, using a Rigaku D/max 2500 v/pc (Japan) operated at a CuKα wavelength of 1.542 Å.

2.6. Apparent density

The apparent density of GO-PVA and RGO-PVA gels, also called bulk density, was defined as the mass of material divided by the total volume occupied [8].

2.7. Ethanol / soybean oil / water adsorption capacity

The dried GO-PVA and RGO-PVA gels (weight = w0) were immersed in ethanol / soybean oil / water for 0.5 h at room temperature. The mixtures were filtered in a funnel under vacuum for soybean oil and gravity for ethanol and water. When there was no more ethanol / soybean oil / water dripping from the filter paper, the gels were weighed (w). The oil adsorption capacity was calculated as follow:

$$\text{Adsorption Capacity} = \frac{w - w_0}{w_0} \qquad \text{Eq. (1)}$$

2.8. MB adsorption experiments

Adsorption experiments were conducted using glass bottles containing 0.3 g L-1 of GO-PVA or RGO-PVA and MB dye (0.1 mmol L−1). The glass bottles were placed on a slow-moving platform shaker and aliquots of approximately 10 mL were taken at different time intervals during the reaction. The MB concentration in the solution were analyzed by UV-Vis spectrometry and relative dye adsorption versus reaction time determined at 30 ºC.

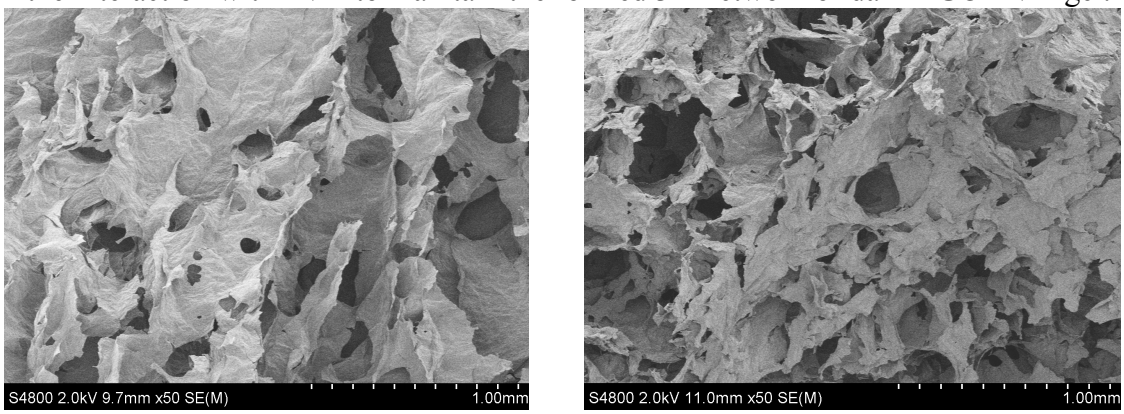
Adsorption isotherm testing showed the concentration of the adsorbent was 0.3 g L−1 and the dye concentrations changed from 0.01 to 0.3 mmol L-1. These experiments were carried out at 30 ºC and all suspensions were shaken on a rotary shaker at 100 rpm for 24 h to reach the adsorption equilibrium.

3. Results and discussion

3.1 SEM

As shown in Fig. 1, the macro-pores led to a 3D network composed of randomly oriented GO sheets. Therefore, it was reasonable to conclude that a loose dynamic GO network existed in the original dispersion of GO sheets owing to the binding interaction [9]. PVA could interact with GO,

owing to the between the oxygen containing groups of GO and PVA. The randomly oriented sheet-like structure of GO gels was consolidated by PVA. The residual oxygen groups of RGO could form the interaction with PVA to maintain the formed 3D network of dark RGO-PVA gel.



(a) (b)

Fig.1. SEM images of GO-PVA (a) and RGO-PVA (b).

3.2 XRD

Fig. 2exhibits the XRD patterns of GO, GO-PVA and RGO-PVA. According to the Bragg diffraction equation $2d\sin\theta=\lambda$ (λ is the CuKα wavelength of 1.542 Å), the feature diffraction peak of GO at $2\theta = 10.81°$ (001) is observed with interlay space (d-spacing) of 0.82 nm. In GO-PVA, this vale was further increased to 1.04 nm, as the feature diffraction peak of GO shifted to $2\theta = 8.44°$ (001). After exfoliation and reduction of GO-PVA, the regular stacks of GO were destroyed and the diffraction peak became disappeared. Meanwhile, a peak of RGO for RGO-PVA at $2\theta = 21.72°$ was observed, indicating that RGO existed individually and highly disorderly in single or fewer layers [10]

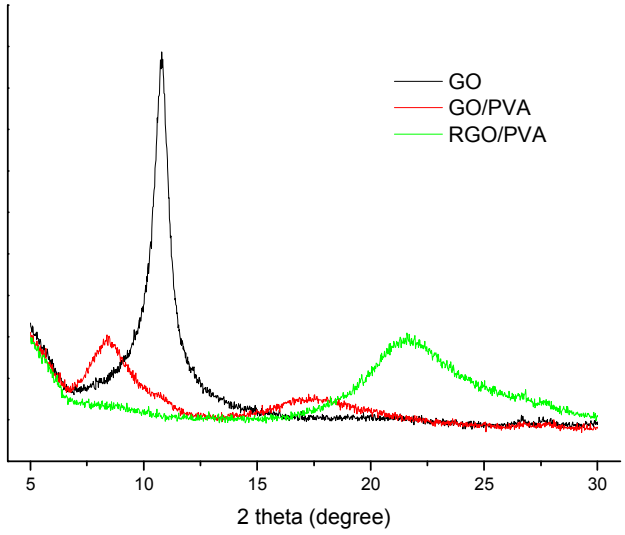


Fig.2. XRD patterns of GO, GO-PVA and RGO-PVA.

3.3. The adsorption of water, ethanol and soybean oil

Table 1 shows the bulk density of GO-PVA and RGO-PVA gels, and the adsorption of water, ethanol and soybean oil. GO-PVA was ultralight with bulk density of 10.52 mg/ cm3, and RGO-PVA was only 11.42 mg/cm3. These macropores of 3D gel network could withhold much liquid. Three liquids with different polarity were adsorbed by GO-PVA and RGO-PVA gels. As listed in Table 1, GO-PVA and RGO-PVA exhibited effective adsorption of the liquids. These macropores could withhold water 37.9-17.5 times, ethanol 40.7-20.6 times and soybean oil 48.7-36.4 times the weight of the gel. The less the polarity of the liquid was, the more the adsorption for both GO-PVA and RGO-PVA gels was. RGO-PVA gel exhibited the soybean oil adsorption as much as 48.7 g/g.

Contrastively, the adsorption capacity of vegetable oil by graphene gel was about 17 times [11]. And silica or rectorite gels absorbed the oils by nearly 15 times [12, 13].

Table 1 Parameters for GO-PVA and RGO-PVA gels

	Bulk density (mg/cm^3)	Water adsorption (g/g)	Ethanol adsorption (g/g)	Oil adsorption (g/g)
GO- PVA	10.52	37.9	40.7	48.7
RGO-PVA	11.42	15.0	20.6	36.4

3.4. Adsorption of MB dye

Fig. 3 illustrates the effects of contact time on adsorption of MB by GO-PVA or RGO-PVA gel. The adsorption of MB by GO-PVA was high and rather fast. At 30 ºC the adsorption equilibrium from the experimental curve reached 120.3 mg g-1 after 2 h for GO-PVA, while for RGO-PVA the amount of dye adsorbed at equilibrium was 71.5 mg/g after 14 h. These facts suggest electrostatic interaction is the primary binding strength between the oxygen containing groups of GO and MB [2], allowing GO-PVA to adsorb more MB than RGO-PVA.

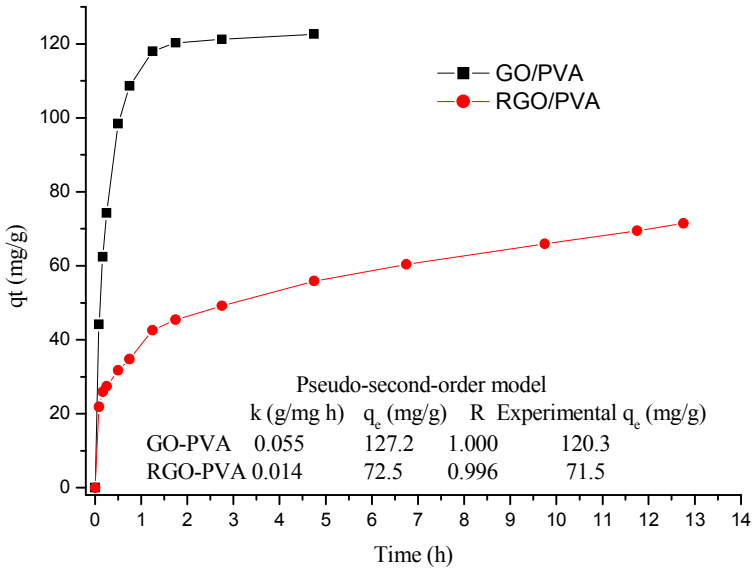

Fig. 3. Effect of contact time on adsorption of MB by GO-PVA and RGO-PVA at 30 ºC. Initial concentration: MB 37.39 mg L-1; GO-PVA or RGO-PVA 0.3 g L-1. The dye adsorption kinetic constants of GO-PVA and RGO-PVA modeled by a pseudo second-order equation were listed in figure.

The kinetic model, pseudo-second-order, was used to investigate the mechanism and rate-controlling step in the overall adsorption process. According to the pseudo second-order model, the amount of dye adsorbed at any time, t (h), is expressed as Eq. (2):

$$\frac{t}{q_t} = \frac{1}{kq_e^{\,2}} + \frac{t}{q_e} \qquad \text{Eq. (2)}$$

where k (mg g-1 h-1) is the second-order rate constant and qt (mg g-1) and qe (mg g-1) represent the amounts of dye adsorbed at any time t (h) and at equilibrium, respectively. The second-order rate constant k and qe can be obtained from the intercept and slope of the line in a t/qt versus t plot. Some kinetic parameters at 30 ºC, estimated from the experimental data and Eq. (1), are listed in Fig. 3. For the adsorption of MB by GO-PVA and RGO-PVA, linear relationships with high correlation coefficients (R > 0.998) between t/qt and t indicated the adsorption process could be well described by the pseudo second-order model. In terms of qe, GO-PVA exhibited better adsorption of MB (127.2 mg g-1) than RGO-PVA (72.5 mg g-1).

The absorption isotherm of MB by GO-PVA is shown in Fig. 4. At low Ce values, the absorption capacities (qe) increase quickly. The qe values increase slowly once Ce is greater than 19.6 mg/L for GO-PVA and 12.6 mg/L for RGO-PVA. The qe value is 573 mg/g for GO-PVA, while the qe value is 79.8 mg/g for RGO-PVA.

Adsorption isotherms are essential for the process of adsorption. The experimental data were applied by the isotherm models of Langmuir Eq. (3). The equations are as follows:

$$\frac{C_e}{q_e} = \frac{1}{bQ_{\max}} + \frac{C_e}{Q_{\max}} \qquad \text{Eq. (3)}$$

where qe (mg/g) is the sorption capacity at equilibrium; Qmax (mg/g) is the maximum adsorption capacity; Ce (mg/L) is the equilibrium concentration in the solution.

The parameters of the Langmuir isotherm are exhibited in Fig. 4. It was found that the adsorption fit this model well. The maximum monolayer adsorption capacities of the adsorbents were 571.4 and 81.0 mg/g for GO-PVA and RGO-PVA, respectively. The Qmax value of GO-PVA is competitive with that of other carbon-based absorbents, such as active carbon (454.2 mg/g) [14] and graphene oxide/calcium alginate composite (181.81 mg/g) [15].

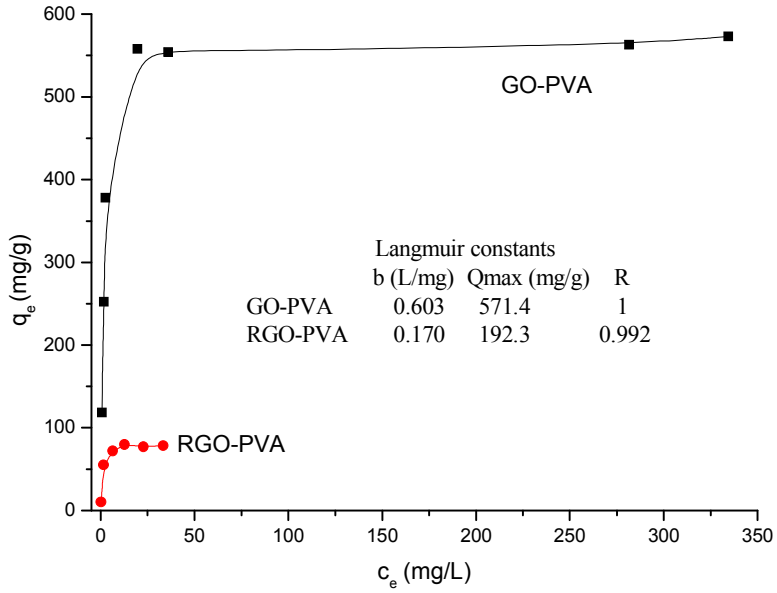

Fig. 4. Adsorption isotherms of MB onto GO-PVA and RGO-PVA at 30 ºC. MB concentrations changed from 0.01 to 0.3 mmol L^{-1}; GO-PVA or RGO-PVA 0.3 g L^{-1}. The Langmuir constants of GO-PVA and RGO-PVA were listed.

4. Conclusion

The ultra-light GO-PVA gel was successfully prepared using a simple process of aqueous gel precursor freezing, solvent exchange (ice-ethanol), and ethanol drying. The 3D porous sheets networks were formed in gels, composed of many macropores, which exhibited low density and high adsorption for water, ethanol and oil. GO-PVA gel with the low density (10.52 mg/cm^3) could respectively withhold water 37.9 times, ethanol 40.7 times and soybean oil 48.7 times the weight of GO-PVA gel, while RGO-PVA gel exhibited lower density (11.42 mg/cm^3), and less water 15.0 times, ethanol 20.6 times and soybean oil 36.4 times. The equilibrium and the dynamic adsorption of MB dye onto the gels were studied. The kinetic process was well described by the pseudo-second-order model. The isotherm adsorption fit well with Langmuir model, and the maximum adsorption capacities were 571.4mg/g for GO-PVA and 81.0 mg/g for RGO-PVA at 30 ºC. GO-PVA and RGO-PVA gel is an efficient adsorbent, which can have potential applications in food, pharmaceuticals, agriculture, cosmetics, pulp and paper, and other industries.

Key words: high strength steel (HSS); recent research progress; seismic; application

Abstract. A review of recent research on mechanical performance of high strength structural steel (HSSS) in the level of both materials and members is presented, including the static material performance, toughness and mechanical property under cyclic loadings of HSSS, buckling and hysteretic behavior of high strength steel columns (HSSC), the ductility and resistance of bolted connection with high strength steel slices etc. Previous research work shows that the application of high strength steel (HSS) is limited in seismic zone .Finally, two design methods of using HSS in seismic zone are proposed based on current seismic design philosophy.

Introduction

HSSS refers to using microalloying and thermo mechanical rolling technology to produce structural steel with high strength (nominal yield strength $f_y \geq 420$ Mpa), good ductility, toughness and processing performance. HSSS has been successfully applied to multiple steel structure engineering at home and abroad, achieving good economic and social benefits. Since the material performance of HSS is significantly different from conventional steel, the applicability of the HSS in using the existing design terms based on the performance of low carbon steel need to be further verified, or put forward a new design method.

The research progress for HSSS

The basic mechanical performance of HSS. Due to the different production processes and microalloying elements, the mechanical properties of HSS have some changes. As shown in figure 1, with the improvement of steel strength, the length of yield platform shortens. When the intensity exceeds 690 Mpa, yield platform disappears. In addition, when steel strength increases, the ultimate strain value corresponding to steel tensile strength decreases gradually.

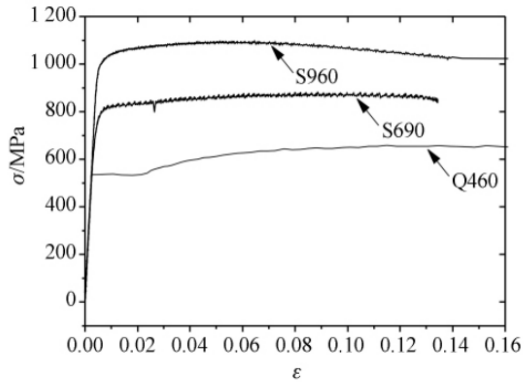

Fig.1 Stress-Strain curves for high strength steels with different grades

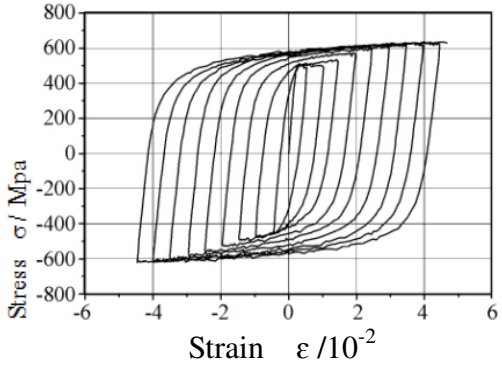
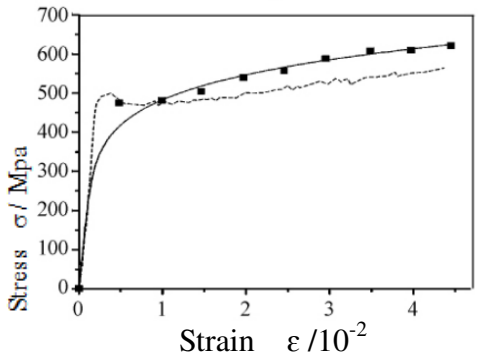
In reference [1] the domestic and foreign material datas of HSS are summarized. Through analysis and comparison, it can be concluded that yield ratio of HSS increases with the increase of steel yield strength. When the yield strength exceeds 690 MPa, yield ratio is roughly 0.90~0.95.The yield ratio reflects the margin of strength (MOS) and deformation capacity(DC) of the material, the higher the yield ratio, the lower the MOS and DC. Elongation also has obvious reduction with the increase of yield strength, while the toughness of HSS is better than traditional steel.

The mechanical performance of HSS under cyclic loading. The mechanical properties of steel structure under the action of cyclic loading and monotonic loading are obviously different, and the former research on seismic performance of steel structure has important significance. Figure 2a is the cyclic stress-strain curve of Q460-C steel in the symmetrical sequential loading condition. In figure 2b, the skeleton data points of cyclic stress - strain curve and the skeleton curve simulated by Ramberg-Osgood model compare with steel monotonic tensile curve. It can be seen from figure 2 that the hysteretic curve of this kind of HSS is plump and the HHS has good energy dissipation ability. In addition, material constitutive relation under cyclic loading has obviously changed, and the Ramberg-Osgood model can be well fitted to its skeleton curve. The test results provide the basis for the determination of constitutive model parameters of HSS in the numerical simulation analysis.



a. Cyclic stress -strain curve



b. Skeleton curve and monotone curve

▪ Skeleton curve data points of cycling test
— Circular skeleton curve
.... Monotonic tensile curve

Fig.2 Cyclic loading test results of Q460-C steel

By cyclic loading test to determine the mechanical properties of the welding connection, it can be found that the maximum intensity of Q460-C welding connection specimens is higher than the parent metal. But the plastic fracture strain is less than the parent metal, and all are broken near the welded seam and heat-affected zone. Hysteresis curve of the welded HSS is still full and it has good energy dissipation capacity [2].

The mechanical properties of HSS at low temperature. The mechanical properties of Q460 - C domestic HSS and its welding connection at low temperature were studied by domestic scholars, including three groups of experiments, namely the basic static tensile, impact toughness and fracture toughness .The study of the yield strength, yield ratio, elongation and other mechanical properties were conducted comprehensively as well. The results show that the domestic HSS has very good impact ductility indicator at normal temperature, but when the temperature is below - 20℃, the toughness decreases significantly, even lower than the relevant standard limits of structural steel in our country.

Overall stability of HSSC under axial compressive force. There are a small amount of experimental researches on overall stability of HSS compression members abroad .The overall stability of five 690 Mpa welded I-shaped cross-section steel column which are unstable around the weak axis and six 690 Mpa welded box section steel column was researched by Rasmussen[3] Usami[4] did research on the overall stability of five 690Mpa welded box section steel column as well.The results show that under the condition of the same axial compressive force, the overall stability coefficient of HSSC is obviously enhanced and significantly higher than that of the

ordinary strength steel column. The existing design method for HSS is too conservative, and when the strength of HSS is more than 690 Mpa , the overall stability coefficient will no longer increase.

Local stability performance of short column of HSS under axial compressive force.

Reference [3] reports the abroad test results of short column of 690 MPa grade HSS, and compares the test results with the limiting value of width-to-thickness ratio in GB 50017-2003 code for design of steel structures. The results show that the limiting value of flange width-to-thickness ratio in GB 50017-2003 is agreed with the test results very well. And the standard still applies to 690 Mpa grade welded steel column of HSS. Tsinghua University [5] did researches on the local stability of thirteen Q460 HSS short column of welded I-shaped cross-section and box section, and compared the test results with calculation methods of local buckling critical stress of box section plate in the GB 50017-2003. Results show that the calculated value of GB 50017-2003 is obviously on the low side, and local stability design of short column of Q460 HSS is too conservative and need to be revised.

Hysteretic performance of bending component of HSS. Studies abroad of hysteretic performance of HSS bending component is very few. Tsinghua University studied on eleven Q460 domestic HSSC of welded I-shaped cross-section and box section under low cyclic loading. Experiment shows that the hysteresis curve of Q460 HSSC is full and the capacity of seismic energy dissipation is good. Furthermore, there is no damage phenomenon of brittle fracture, and width-to-thickness ratio and ratio of axial compression stress to strength of a plate have a significant impact on the seismic performance .The limiting value of width-to-thickness ratio and ratio of axial compression stress to strength of a plate have significant correlation. The calculation formula of the limiting value should be fully aware of the influence of ratio of axial compression stress to strength.

The mechanical performance of shear connection of HSS bolt. Tests on bolt shear connection of nine domestic Q460 steel plate have been carried out by ShiGang[1]. The test results show that the hole wall bearing performance of Q460 steel plate are not well predicted by the design methods of European standard Eurocode 3 and American standard ANSI/AISC360-05.And the calculation results of design are relatively unsafe. There is no mature design method in our country, so new secure design theory and calculation method of HSS shear connection need to be put forward.

The two ideas of the application of HSSS in seismic fortification zone.

With the increase of steel strength, the yield ratio increases while the elongation decreases. As a result, the performance of the HSSS can not meets the requirements of GB 500117—2010 Code for seismic design of building. It can be seen from the mechanical performance index that the steel whose nominal yield strength is higher than 420 MPa can not be used for a seismic structure .And because the only supplement of the Q420 steel in GB 500117—2010 ,the application of the Q460 HSSS and other higher grade steel is restricted.

In order to solve the problems mentioned above, we put forward two kinds of solutions based on the principles of seismic design: one is to improve the seismic action of the HSS structure of poor ductility in the design to insure the reliability of the structure; the other is to set up a special energy dissipation device to consume a large amount of seismic energy under strong earthquakes. So that the situation that HSS structure first yield under strong earthquakes can be avoided.

Improving the seismic action. As shown in figure 3, for a good ductile structure, seismic energy can be dissipated through plastic deformation, so the structure is not severely damaged or collapsed. Therefore, the seismic action of a good ductile structure in design can be reduced appropriately. On the contrary, a structure which has poor ductility should improve the seismic action in design.

Limiting the HSSS to yield. Based on the concept of the capacity design, through the energy consumption after the ductile members yielding to ensure the inductile members are always in the elastic stage under rare earthquakes, therefore the safety of the whole structure can be guaranteed. The research on the examples of seismic damage and the results of theoretical analysis indicate that the shortage of deformation capacity (DC) and energy-dissipating capacity (EDC) is the main reason for the collapse of structure under rare earthquakes [6] .To ensure the HSS structure does not collapse under rare earthquakes, the structure need to have enough DC and can form the effective energy-dissipating mechanism. Semi-rigid joint has good DC and good EDC, therefore the semi-rigid frame structure can be used to ensure the good deformability(as shown in figure 4). The

energy-consuming components as the fuse of the structure first yield under the strong earthquake and dissipate the seismic energy through the plastic deformation, so that the HSS members are in the elastic stage under the strong earthquake.

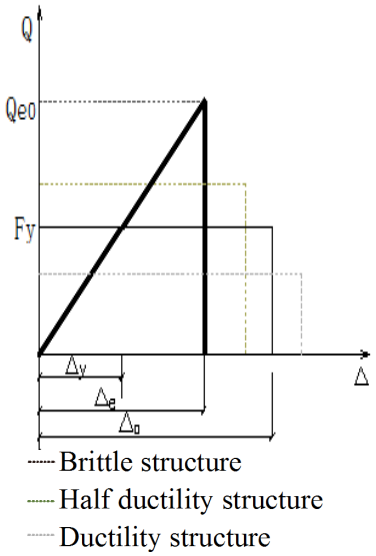


Fig.3 Effect of ductility on requirement of earthquake action

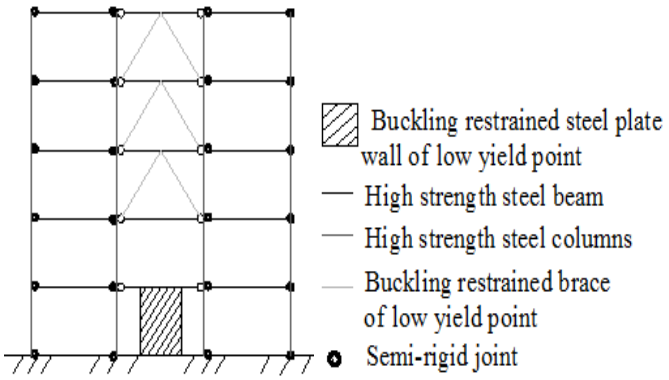

Fig.4 Structural system providing elastic design of HSS member

Conclusion

The existing study results show that HSSS have good mechanical performance, but many design methods of existing specifications are not suitable for HSSS. In addition, the design methods are too conservative and not conducive to advantages in such structural steel. The existing research results have important guiding significance in improving the design method and calculation theory of HSSS .On the basis of the existing research results, the projects need more practical application of HSSS to verify the rationality of the research results and promote new research topics to be presented in the meantime.

Keywords: rare-earth, stannate, coprecipitation

Abstract. A series of Eu^{3+}, Dy^{3+} actived $Ca_{1-x}Ba_xSnO_3$ phosphors were synthesized by coprecipitation method. The structure, morphology and fluorescence property of phosphors were investigated by using X-ray diffraction (XRD), scanning electron microscopy (SEM) and fluorescence spectroscopy. SEM results showed that the as-prepared phosphors are smooth and uniform with the cubic morphology. The incorporation of a small amount of Ba to $CaBaSnO_3$ improved the emission characteristics. Fluorescence spectrum showed the emission intensity is the best with the incorporation of Ba^{2+} (x = 0.3), when calcination temperature is 900℃.

Introduction

White light-emitting diodes (LEDs) are considered to be the fourth generation solid state lighting sources which are following the incandescent, fluorescent and high intensity discharge lamp due to their high efficiency, long lifetime, safety and environmentally friendliness etc [1]. Phosphor is one of the key components in WLED, and the red phosphor has two main purposes [2]. First, by combining the green phosphor with a blue LED chip to produce white light, or fabricated with green as well as blue phosphor to produce white light with near ultraviolet LED chip; Second, for improving the color rendering index or lower color temperature, it is used for compensating the yellow phosphor excited by blue LED chips to produce white light which is in the absence of red. In this case, it is essential to search novel red phosphors for WLED, and the preparation of the red luminescent material with a good performance is the direction of the present study.

Phosphors based on stannate have attracted more and more interest in recent years. Rare-earth stannate is an isometric crystal oxide, with a typical pyrochlore structure. Alkaline earth slant stannate is a composite metal oxide with cubic and perovskite structure. In addition, M^{2+} and O^{2-} constitute the approximate cubic close packing structure [3-6]. So far, the study of $CaBaSnO_3$ is still relatively scarce, which is necessary to conduct a detailed study.

Experimental

$Eu(NO_3)_3$ solution was prepared by dissolving a certain amount of Eu_2O_3 into HNO_3. Then stoichiometric weights of $Ca(NO_3)_2$, $Ba(NO_3)_2$ and $SnCl_4$ were dissolved in water. The flocculent precipitates were obtained after mixing the above solutions under slow titration with ammonia, with the pH of 7. The obtained precipitate was filtered, washed and then dried at 80℃ for 8h. Then the samples were calcined at high temperatures to obtain stannate phosphor powder.

Results and discussion

XRD analysis. The crystal structures of the synthesized samples were determined by powder X-ray diffraction(XRD) using a copper Kα radiation source at 40 kV and 200mA in steps of 0.02. Data were recorded ranging from 10° to 90°.

The XRD patterns of $Ca_{1-x}Ba_xSnO_3$: Eu^{3+}, Dy^{3+} composites which were calcined at 900℃ for 5h is shown in Fig.1, whose reflection peaks can be readily indexed with the cubic perovskite $CaSnO_3$ (JCPDS No. 1-998) [7]. No other phase can be detected, indicating that Ba^{2+} has been dissolved successfully in crystal lattice. And the crystal structure of $CaSnO_3$ is shown in Fig.2, which belongs to the peroskite structure. It can be seen that lattice parameters are a=b=c=7.8900Å and space lattice group is Fm-3m.

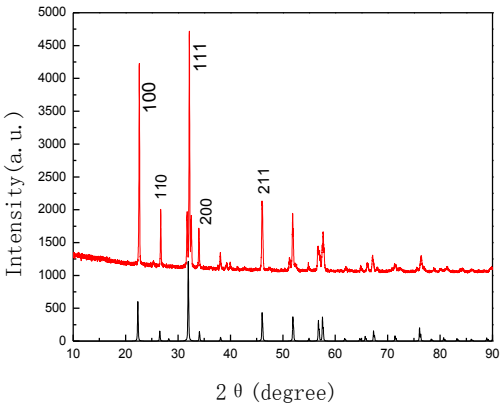

Fig.1 XRD pattern of $Ca_{1-x}Ba_xSnO_3$: Eu^{3+}, Dy^{3+}

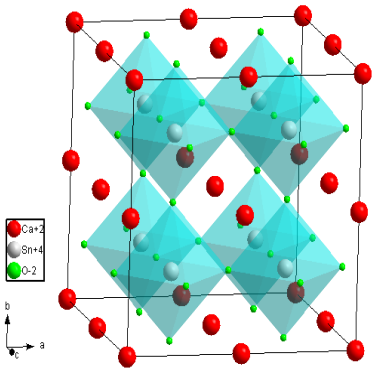

Fig .2 Crystal structure of $CaSnO_3$

Fluorescent properties. Fig.3 shows the room temperature photoluminescence excitation (PLE) (the left half of the curve) and emission (PL) spectra excitated at 395nm and 465nm (the right one).

The excitation spectra of $Ca_{1-x}Ba_xSnO_3$: Eu^{3+}, Dy^{3+} exhibits five obvious excitation peaks located at 361, 383, 395, 415 and 465 nm, which are corresponding to the $^7F_0 \rightarrow {}^5D_4$, $^7F_0 \rightarrow {}^5L_7$, $^7F_0 \rightarrow {}^5L_6$, $^7F_0 \rightarrow {}^5D_3$ and $^7F_0 \rightarrow {}^5D_2$ transitions of Eu^{3+} ion, and the higher excitation peaks are located at 395 nm and 465 nm. The excitation peaks which are located at 395 nm and 465 nm match well with the near ultraviolet LED chip (370 nm to 410 nm) and the blue LED chips respectively. So, it not only can be applied to the near ultraviolet excitation WLED but also can be applied to the blue light excitation WLED.

The emission spectra of $Ca_{1-x}Ba_xSnO_3$: Eu^{3+}, Dy^{3+} exhibits four obvious emission peaks. The peak at 578 nm is due to the magnetic dipole $^5D_0$-$^7F_0$ transition of Eu^{3+}, and the peaks at 589nm and 596nm are due to the magnetic dipole $^5D_0$-$^7F_1$ transition of Eu^{3+}. A broader and stronger emission band with a peak at 613nm is attributed to the $^5D_0$-$^7F_2$ transition of Eu^{3+}. $^5D_0$-$^7F_0$ and $^5D_0$-$^7F_2$ transition emission produced a splitting that is due to $^5D_0$-$^7F_1$ magnetic dipole transition emission of orange color. As the electronic transitions general rule of Eu^{3+} is well known, Eu^{3+} is in the strict inversion center at this time.

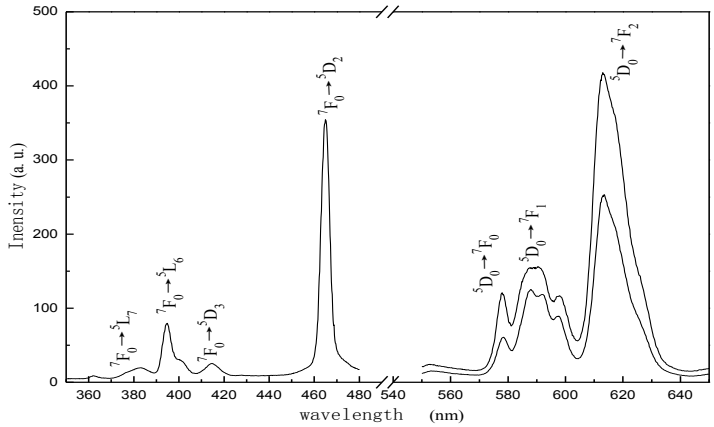

Fig.3 PLE and PL spectra of $Ca_{1-x}Ba_xSnO_3$: Eu^{3+}, Dy^{3+}

The influence of Ba^{3+} concentration. Fig.4 shows the emission spectra of the $Ca_{1-x}Ba_xSnO_3$: Eu^{3+}, Dy^{3+} with various Ba^{3+} concentration.

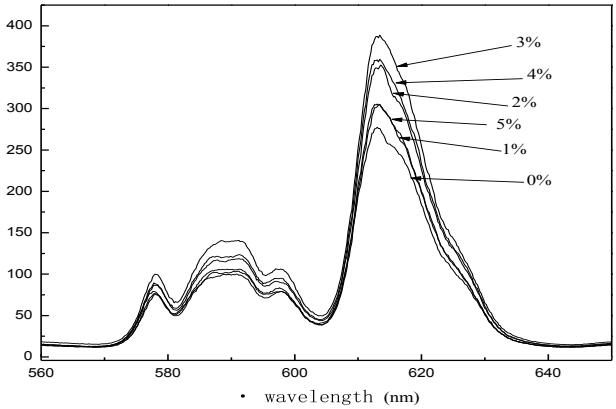

Fig.4 Emission spectra of the $Ca_{1-x}Ba_xSnO_3$: Eu^{3+}, Dy^{3+} with various Ba^{3+} content

As can be seen from Fig.4, with the Ba^{3+} concentration increased, the shape of the emission spectra and emission peak position don't chang, but the luminous intensity of emission peak increase. Compare to the fluorescence properties of undoped Ba^{2+} phosphor, the intensity of each emission peak increases. When the doped concentration of Ba^{2+} is up to 3%, the emission intensity is the best. The reason is the introduction of Ba^{2+} destroys the original Ca_2SnO_3 lattice layout. Since the dopant ions of Ba and Ca are in the same main group with similar nature, solid solution can be more easily formed. While the introduction of Ba resulted in the emergence of new defects and the crystal tends to be deformed. That is beneficial to energy transfer of Eu^{3+} luminescence centers, which will result in a substantial increase in luminescence intensity.

The influence of calcination temperature. Fig. 5 shows the SEM images of samples prepared at different calcination temperatures (800℃, 900℃, 1000℃, and 1100℃).

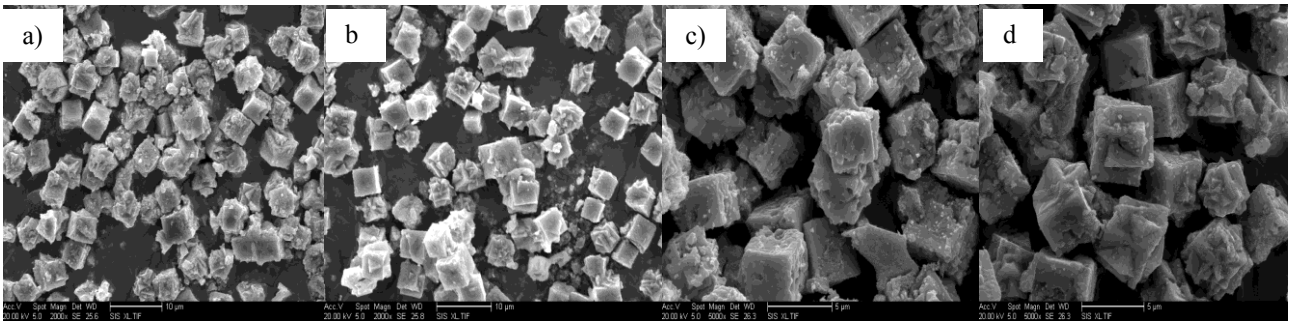

Fig.5 SEM images of $Ca_{1-x}Ba_xSnO_3$: Eu^{3+}, Dy^{3+} at different calcination temperature : (a) 800 ℃; (b)900 ℃; (c) 1000 ℃ and (d) 1100 ℃.

With the calcination temperature increasing, the regularity of surface morphology of samples improved, the morphology changed from irregular to regular and uniform particles consistency improved gradually. When the calcination temperature reaches up to 900 ℃, the particle size and surface smoothness can get the optimal value. But when the calcination temperature is further increased, the prepared samples are irregular and the adhesion and aggregation. This is mainly because that the external high temperature accelerates the grain development of luminescent material fully. With the temperature increasing, the integrity and homogeneity of crystal will obviously increase and the internal defects reduce. However, when the calcination temperature is too high, it makes the grain grow excessively and agglomeration occurs.

The emission spectra of the samples calcined at different temperature are shown in Fig. 6. As can be seen from Fig.6, with the increase of calcination temperature, the shape of the emission spectra and emission peak position don't chang. The main emission peaks are located in 578, 589, 596 and 613 nm respectively. With the increase of the calcination temperature, the fluorescence intensity increases. When the temperature reaches 900℃, maximum emission peak can be found, while with the temperature further increases, the fluorescence intensity decreases. The main reason is that with

the calcination temperature increases, the grain crystallization is improved, the monodispersed crystals generate and the relative luminous intensity increase. But when being calcined at high temperatures, powder agglomeration occurred, resulting in a loss of luminous intensity. Therefore, when the sintering temperature is 900℃, the emission intensity is the best.

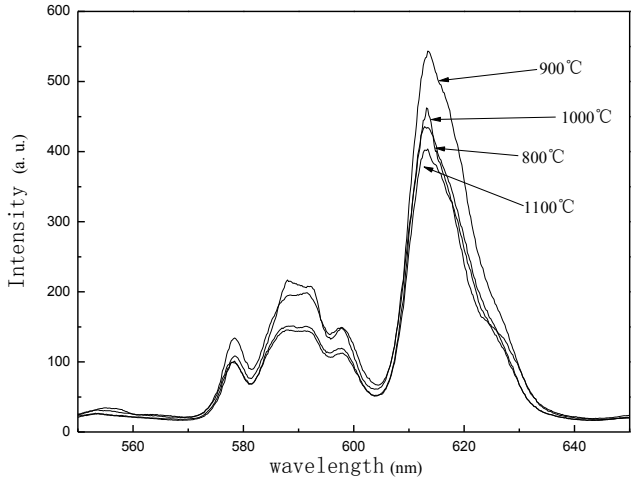

Fig.6 The emission spectrum of the sample calcined at different temperature

Conclusions

A novel red phosphor $Ca_{1-x}Ba_xSnO_3$: Eu^{3+}, Dy^{3+} was prepared by the traditional coprecipitation method. And the structure, morphology and fluorescence properties of the phosphor powders are studied. It was found that the incorporation of a small amount of Ba to $CaBaSnO_3$ improved the emission characteristics. Fluorescence spectrum observations showed that the emission intensity is the best with the incorporation of Ba^{2+} (x = 0.3) and the sintering temperature is 900℃.

Keywords: GaN, dislocation, thickness, HRXRD, AFM.

Abstract. The dislocation density of GaN thick films has been measured by high-resolution X-ray diffraction. The results show that both the edge dislocations and the screw dislocation reduce with increasing the GaN thickness. And the edge dislocations have a larger fraction of the total dislocation densities, and the densities for the edge dislocation with increasing thickness reduce less in contrast with those for the screw dislocation.

Introduction

GaN has attracted much attention for a wide range of application due to its excellent optoelectronic properties [1]. The defects of the material such as threading dislocations (TDs) have a negative effect on device properties. TDs can act as non-radiative recombinant limiting the efficiencies of light-emitting diodes (LEDs) [2], charged scattering centers reducing carrier mobility [3] and can reduce the leakage current in p-n junctions [4]. The main reason for defect onset is both mismatching of crystal lattice parameters and thermal expansion coefficients between GaN and sapphire used as a substrate. The sustained interest is driven that require the growth of GaN epilayers with ever lower TDs densities for next-generation high-brightness LEDs [5].

Several techniques for the reduction of dislocation density have been proposed for the III-nitride materials [6–11]. Among them, epitaxial lateral overgrowth has been successfully used for the commercialized optical devices. The efforts for further TD reduction have been limited by the additive cost, because it need lithography technique or complicated growth processes.

General, the dislocations in GaN/sapphire originates the interface between GaN and sapphire [12]. And the thicker GaN films would have the lower TDs. However, only few works has been done for the influence of the thickness, where the thickness in those research is only around 20~30μm. In this paper, we have studied the relation between the dislocation densities and the thickness in GaN film with the thickness of several hundred μm. We have also discussed the mechanism among them.

Experimental

In this study, GaN films have been grown by hydride vapor phase epitaxy (HVPE) on sapphire with the thickness of ~670μm. Free-standing thick GaN wafers grown by hydride vapor phase epitaxy and lifted off from the substrate is currently the most feasible way for the substitution of a real bulk material. The growth rate is up to several microns per hour. Here, the edge and screw dislocation densities have been measured by diffuse X-ray scattering from epitaxial layers based on the mosaic crystal approximation was used in [13].

High-resolution X-ray diffraction (HRXRD) measurements have been performed using a PANalytical X'Pert PRO MRD diffractometer and the X-ray radiation is Cu Kα (wave length λ is 0.15406 nm). The rocking curves of reflection (002), (004), (006), (101), (102), (103) are obtained by each measurement.

The sample have been mechanical ground and polished using horizontal rotary grinding machine and single side lapping machine respectively. The film shows a smooth surface with a root mean square surface roughness < 1nm determined by atom force microscope (AFM). Each time, the sample is polished off 70~80μm and HRXRD analysis is performed after each polishing.

Result and Discussion

Fig. 1 is the AFM image of the polished GaN. It can be seen that it is smooth and uniform after the polishing. The RMS roughness is 0.650792nm. It is well-known that both instrumental and sample-related reasons will cause the broadening of the XRD peak. But the instrumental broadening will be negligible by using high-resolution X-ray diffraction.

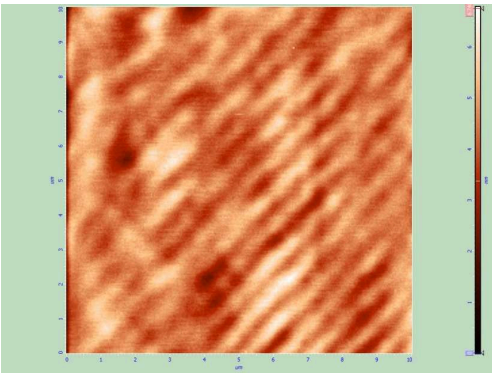

Fig. 1 AFM image of the polished GaN sample

The densities of dislocation of the thicker GaN film are measured by X-Ray Diffraction (XRD) techniques. We can use the following equation to obtain the densities of the screw dislocation Ns [14]:

$$N_S = \frac{\alpha_\Omega^{\,2}}{4.35\mathbf{b}^2} \quad (1)$$

Where b ($|\mathrm{b}|$ = 0.518nm) is the Burgers vector of the screw dislocation.
The densities of the edge dislocation Ne can be obtained by the equation as follow [14]:

$$N_e = \frac{\alpha_\varphi^{\,2}}{4.35\mathbf{b}^2} \quad (2)$$

Where b ($|\mathrm{b}|$ = 0.518nm) is the Burgers vector of the screw dislocation.
Using the method shown in previous report [12], we have obtained the dislocation density variation with the thickness in GaN film, where the screw and edge dislocation density is shown in Fig. 2 and Fig. 3, respectively.

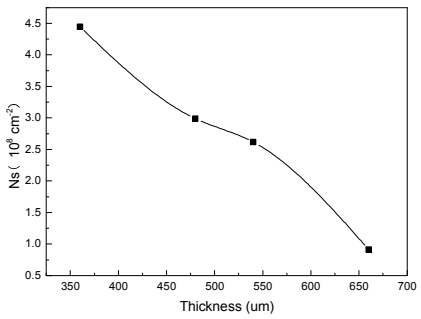

Fig. 2 The screw dislocation density variation with thickness in GaN film

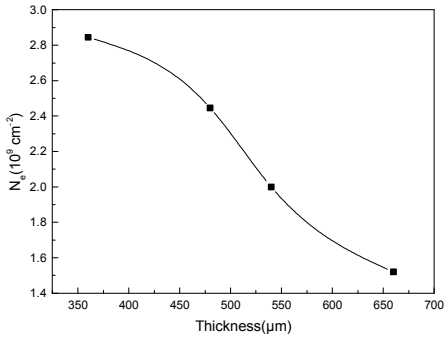

Fig. 3 The edge dislocation density variation with thickness in GaN film

From Fig. 2 and Fig. 3, we can conclude that the densities for the edge and screw dislocation decrease with increasing the GaN thickness, which is in agreement with our impression. We think that the main mechanisms for dislocation densities reduction in films are fusion or annihilation. Dislocations may meet and react with others when they get close proximity during the growth. A fusion happens when two dislocation lines become one dislocation line with the new Burgers vector **b**3 = **b**1 + **b**2. When two dislocations with opposite Burgers vectors react, an annihilation reaction occurs to remove the dislocations entirely [15]. It is found that the line directions for edge and screw dislocations are [0 0 0 1] and 15.6° for the mixed dislocations [15]. The edge-mixed reactions produce the screw dislocations and the screw-mixed reactions produce the edge dislocations. As the film thickness increases, the inclined dislocations move laterally and meet with one another, so the fusion or annihilation will happen.

The results in Fig. 2 and Fig. 3 also demonstrate that the densities for the edge dislocation with increasing thickness reduce less in contrast with those for the screw dislocation: N_{e1} is 1.5201×109 cm^{-2} at 660μm and N_{e2} is 2.8440×109 cm^{-2} at 360μm decreasing by 47.6% while N_{s1} is 9.1280×107 cm^{-2} at 660μm and N_{s2} is 4.4451×108 cm^{-2} decreasing by 80.5%. It can be explained as follows: edge dislocations usually occur during the initial stages of GaN growth when small misoriented GaN islands coalesce to form a continuous thin film. These edge dislocations usually parallel to the c-axis with a small tilt angle, so it is more difficult to meet and fuse for two or more edge dislocations than that of screw dislocations. The screw-edge reactions also have small possibilities because their each Burgers vector is perpendicular and the major fusion for the reduction of the edge dislocation densities are the edge-mixed reactions. On the other hand, the screw dislocations' shape is like half-loops which are extended along the c-axis and they have two screw segments whose line directions are opposite [17]. Two types of screw dislocations exist with Burgers vector **b** = ± [0 0 0 1]. As a result, the screw dislocations can fuse with each other and they also fuse with mixed dislocations through the screw-mixed reactions. For this reason, the reduction of the densities for the edge dislocation is very limited in thicker GaN films compare with screw dislocation densities.

Besides, the edge dislocations have a larger fraction of the total dislocation densities. The edge dislocations possess 86.6% of the all dislocations in 360μm thick while the fraction is 94.4% of total dislocations in 660μm. It should be noted that the variation tendencies of the Fig. 2 and Fig. 3 are inverse correlations which means that the edge dislocation fuse and reduce faster than the screw dislocation. The reason is that faster fusion between edge and mixed dislocations make fewer mixed dislocations available for the screw-mixed fusions. When the mixed dislocation is depleted and no further fusions for the edge dislocations are possible. So the densities for the edge dislocation reduce more slowly when GaN film reaches a certain thickness.

Conclusions

In this paper, the dislocations density of GaN thick films has been measured by high-resolution X-ray diffraction. The results show that the density of edge and screw dislocation decreases with increasing the GaN thickness. It also demonstrates that the densities for the edge dislocation with increasing

thickness reduce less in contrast with those for the screw dislocation. And the edge dislocations have a larger fraction of the total dislocation densities. We have discussed the mechanism of reduction of the dislocations with the thickness. So, HVPE for thick GaN films is a feasible method to reduce threading dislocations.

Keywords: WLED, Green light-emitting, Rare earth doping, $LnPO_4$.

Abstract. LED as the fourth generation light source has been extensively studied. In order to get a high-performance White Light Emitting Diode (WLED) green phosphor, YPO_4:Ce^{3+},Tb^{3+} was prepared by co-precipitation. It was excited at 380nm. The structure, morphology, fluorescence property and colorimetry of the phosphors were investigated by X-ray diffraction (XRD), scanning electron microscopy (SEM) and fluorescence spectrophotometer. Final results show the optimal concentration ratio are 1:0.05:0.01. The crystal grain of luminescent material is 200 nm. When the bath temperature is 80℃ and calcined at 1000℃ for 3h, the luminescence performance of the luminescent material is excellent.

Introduction

Rare orthophosphate $LnPO_4$ has many prominent advantages, such as high thermal stability, large refractive index and low phonon energy[1,2]. It is widely used in Sensors, ceramic, catalyst carrier and host of fluorescent material[3]. YPO_4 has xenotime structure and assigned to tetragonal crystals. In which Y^{3+} radius is small, rare earth ions can replace the Sites of Y^{3+} without destroying the crystal structure[4,5]. Ce^{3+}, Tb^{3+} co-doped YPO_4 is a commercially efficient green phosphor. Environment of luminescent center ion charge can be adjusted by incorporation of other ions. Since Ce^{3+} 4f layer only has one electron, it has prominent contribution on compensation ion charge environment and sensitizing excited center Tb^{3+}[6].

In a typical process for the synthesis of YPO_4 under high temperature solid state conditions, rare earth oxides and $(NH_4)_2HPO_4$ as raw materials. But the high-temperature lead to P_2O_5 evaporate, causing the ratio of phosphate and rare earth ions can't control. the luminescence properties of phosphors was affected. Precipitation method can solve many problems of solid-phase reactions. Obviously in the solution, it's easy to control the stoichiometric ratio of phosphate and rare earth ions. At the same time it can also make doping ions mixed evenly into the lattice matrix[7].

Experiments

Preparation. The Y_2O_3, Tb_4O_7, $Ce(NO_3)_3$, HNO_3 were selected as the raw material. First, according to the stoichiometric ratio of the elements accurately weighed. In a typical synthesis procedure, Y_2O_3 and Tb_4O_7 were dissolved in HNO_3 with stirring. Diammonium phosphate was dissolved in the as-prepared $Y(NO_3)_3$ and $Tb(NO_3)_3$ aqueous solution under stirring. The mixture was transferred into a flask and stirred at 80℃ in a water bath. Dropwise added the Diammonium phosphate solution. Heavy white precipitate can be seen and continue added until complete precipitation. The resulting precipitate was suction filtered and washed, then placed in a resistance furnace for calcining phosphor obtained.

Characterization. The structures of the phosphor were characterized by X-ray diffractometer (XRD)(Shimadzu, XRD-6000, Cu Ka target) and the morphology of the particles was observed by field emission scanning electron microscope(FE-SEM)(Sirion 200, Philip). The photoluminescence

properties. of the phosphors were studied on fluorescence spectrophotometer (Shimadzu, model RF-5301 PC).

Result and discussion

Structural analysis. Fig. 1 shows the X-ray diffraction (XRD) patterns and crystal structure of $Y_{1-x}PO_4:xTb^{3+}$ and $Y_{1-x-y}PO_4$: xTb^{3+},yCe^{3+}. All the diffraction peaks are in good agreement with the standard positions from the quartet YPO_4 phase(11-0254), and no diffractions from Tb_2O_3 and Ce_2O_3 can be detected, implying the completely substitution of Tb and Ce to Y and without charge compensation.

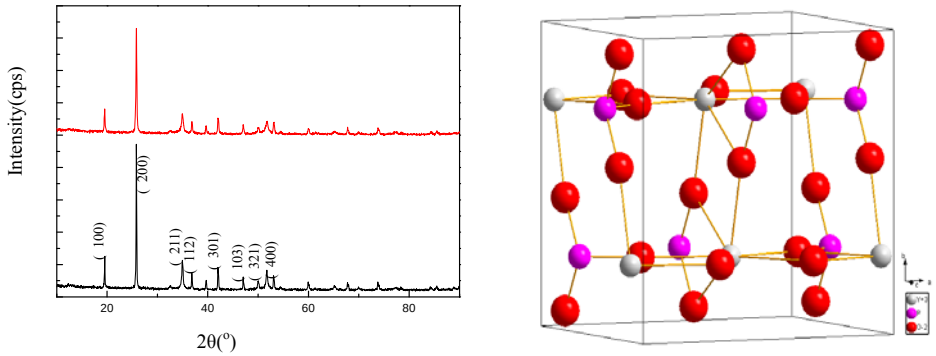

Fig. 1 The XRD patterns and crystal structure of $Y_{1-x}PO_4:xTb^{3+}$ and $Y_{1-x-y}PO_4$: xTb^{3+}, yCe^{3+}.

Fig. 2 shows the XRD patterns of YPO_4:5%Tb^{3+},2%Ce^{3+} calcined at 1000℃ of different time. The shape of the four diffraction peak is almost the same without extra miscellaneous peak. When the calcination time is 1h, the FWHM (Full Width at Half Maximum) is large, which is assigned to inadequate decomposition of organics. Many ions(oxygen ions, hydroxide ions) enter into the crystal interior and combine with lattice point, even destroy the lattice crystal. The sharpness of 2h is higher than 1h. When the calcination time up to 3h, not only the sharpness becomes higher but also the FWHM becomes more narrow. The crystalline phase is fully reflected. With the increasing of the calcination time, the material was burnt. Crystal agglomeration or crystal structure destruction result a significant reduction in the sharpness of the diffraction peaks. So the best calcination time is 3h.

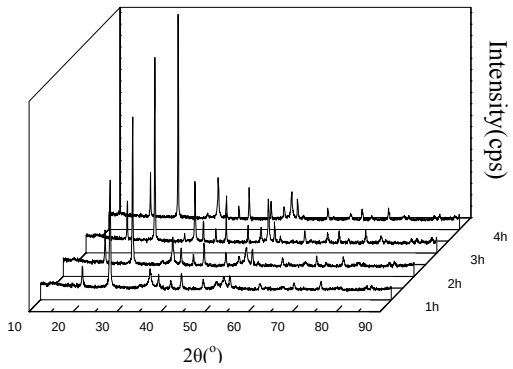

Fig. 2 The XRD patterns of YPO_4:5%Tb^{3+},2%Ce^{3+} calcined at 1000℃ of different time.

Optical characterization

Luminescence performance analysis of $YPO_4:Tb^{3+}$. In order to determine the optimum molar ratio of Tb^{3+}, we designed four horizontal test wherein Tb=x%. All the materials were calcined at 900℃of 3h. From the Fig. 3, the optimal luminescence intensity was Tb=5%.

Luminescence performance analysis of $YPO_4:Tb^{3+},Ce^{3+}$. Fig. 4 shows the excitation and emission spectrum of the prepared samples which are calcined at 1000℃ for 3h.From the excitation spectrum we can see that the peak intensity at 380nm is the strongest. The excitation spectra of

$YPO_4:Tb^{3+},Ce^{3+}$ excited by ultraviolet at 380nm exhibits four obvious excitation peaks which are located at 487, 541, 583 and 620 nm, which are corresponding to the $^4D_3\rightarrow{}^7F_6$,$^5D_4\rightarrow{}^7F_5$,$^5D_4\rightarrow{}^7F_4$ and $^5D_4\rightarrow{}^7F_3$ transitions of Tb^{3+} ion. Among that, the peak at 541 nm is obvious, and the emitting light located in green spectral region[8].

It's easy for Ce^{3+} to absorb energy under UV excitation ,but Tb^{3+} is not. Therefore, the characteristic peaks which is corresponding to the $^2F\rightarrow{}^5D$ transitions of Ce^{3+} ion can be found in the excitation spectrum. Ce^{3+} which can be acted as sensitizer has a good ability to transfer the energy to Tb^{3+} . The characteristic peaks of Tb^{3+} which can be ascribed to $^5D\rightarrow{}^7F_j$(j=6,5,4,3)can be found, whereas Ce^{3+} is not.

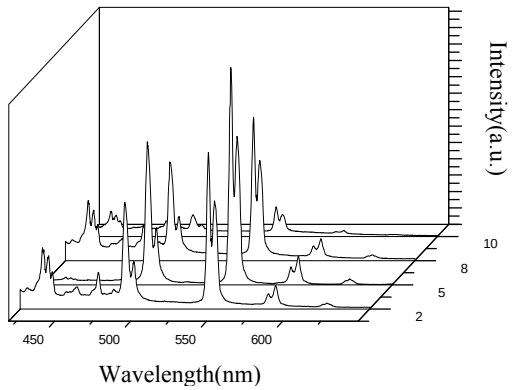

Fig. 3 Luminescence performance analysis of YPO_4:Tb(Tb=2%, 5%, 8%,10%).

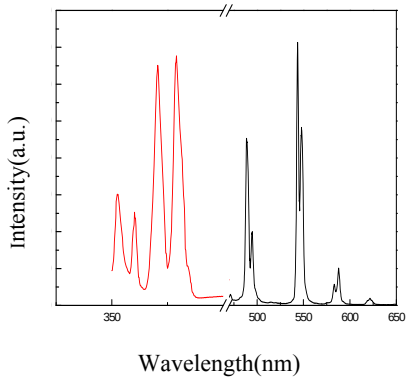

Fig. 4 Excitation(λ_{em}=545nm) and emission(λ_{ex}=380nm) spectrum of material calcined at 1000℃,3h.

The effect of rare earth concentration. Fig.5 shows the emission spectra of YPO_4:0.05Tb:x%Ce. The concentration of Ce^{3+} is 0, 1%, 2%and 4%, respectively. With the concentration of Ce^{3+} increasing, the fluorescence intensity is improved significantly. When the molar ratio of YPO_4: Tb: Ce was set to 100:0.05:0.01, we can get the optimum luminous intensity. In the luminescent material, With the concentration of Ce^{3+} increasing, the energy transfer between Ce and Tb is enhanced. But The concentration quenching occurred when the doping concentration is redundant, and the luminous efficiency dropped.

Concentration quenching,namely with the activator concentration increasing, the luminous efficiency dropped.When the activator reaches a certain value, the interaction between them is enhanced. The probability of non-radiative transition increased result in decreasing of the luminous efficiency.

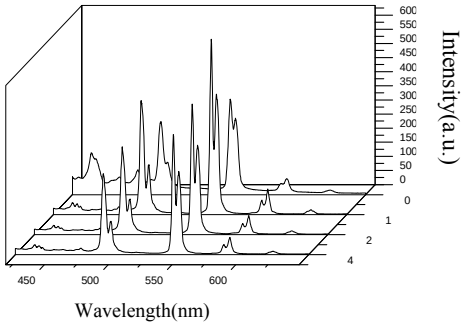

Fig. 5 The emission spectra of YPO_4:0.05Tb^{3+},x%Ce^{3+}.

Morphology analysis. Fig. 6 shows the SEM images of different calcination temperature and the temperature are 900, 1000 and 1100℃ respectively. When the temperature was 900℃, the prepared sample had a relative good morphology, the crystal is not full-grown. The sample under 1000℃ had separated crystal morphology and uniform particles. The particle size is about 200 nm. Fig. 6-c shows the sample calcined under 1100℃. Because of overburning, the lattice crack and crystal phase

liquefaction. This is correspond to the test results of fluorescence intensity. This reflected the effects of morphology on fluorescence performance.

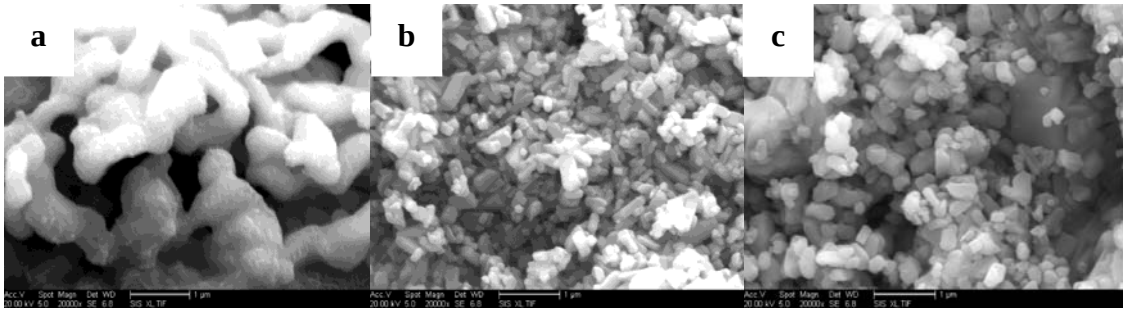

Fig. 6 The SEM images at different temperatures.

Conclusion

A novel green-emitting $YPO_4:Ce^{3+},Tb^{3+}$ phosphor has been synthesized by the traditional coprecipitation method. The excitation spectra of $YPO_4:Tb^{3+},Ce^{3+}$ excited by near-ultraviolet at 380nm. The PL spectra shows that the main emission peak located at 541nm, and the emitting light located in green spectral region. The obtained results show the optimal concentration ratio is 1:0.05:0.01. The crystal grain of luminescent material is 200 nm. When the bath temperature is 80℃ and calcined at 1000℃ for 3h, the luminescence performance of the luminescent material is the best.

Keywords: White light emitting diode, Alkaline earth, Mesosilicate

Abstract. $Ca_2MgSi_2O_7$: Eu^{3+}, Ce^{3+}, Tb^{3+}, a single white Phosphor, was synthesized by the conventional solid-state reaction. The structure, surface morphology and luminescence properties of the prepared samples were investigated to evaluate its potentiality. XRD results confirm the orthorhombic phase of $Ca_2MgSi_2O_7$: Eu^{3+}, Ce^{3+}, Tb^{3+} phosphors. The excitation spectra indicates the phosphor can be excited by 393 nm wavelength. The phosphor exhibits blue light at 467 nm, green light at 588 nm, red light at 618 nm. CIE chromaticity diagram indicates that $Ca_2MgSi_2O_7$: Eu^{3+}, Tb^{3+}, Ce^{3+} exhibits white light. All properties show that the prepared phosphor is a single white phosphor suitable for near ultraviolet excitation which can be applied to new generation white LED lighting.

Introduction

There is a growing worldwide awareness of the need for strengthened environmental and energy protection as people entered the twenty-first century. Currently, the power consumption of lighting can account for 19% of the total power consumption. And the efficiency of incandescent and fluorescent lamps is low, fluorescent lamps also has the problem of environment. WLED have the advantages of lower energy consumption, environmental protection and long lifetime etc[1-3]. The luminescence efficiency has already exceeded that of traditional incandescent lamps and now is competitive with that of fluorescent lamps.

Now, there are three methods to achieve WLED for lighting. One way to produce the white light is to combine the blue GaN chip with yellow phosphor YAG: Ce^{3+}[4]. However, the color quality of these white LEDs has not been fully satisfactory due to the limited white hue tunability, color rendering index, and correlated color temperature. And it is aso difficult to make stable WLED because there are many influencing factors such as the light like drive voltage and coating thickness of phosphor in industrial production. Besides, white light can be produced by mixing blue, green, and red phosphors with near-ultraviolet LED[5-7]. While there is a color reabsorption problem with this approach, it will affect the color reproduction of LED. Single white phosphor does not have the color reabsorption and ratio regulation problems[8], and silicate matrix has a high chemical and thermal stability. $Ca_2MgSi_2O_7$ matrix which can be activated by rare earth ions widely used in the field of LED. Therefore, single white $Ca_2MgSi_2O_7$: Eu^{3+}, Ce^{3+}, Tb^{3+} phosphor has broad application prospects.

Experimental

$Ca_2MgSi_2O_7$: Eu^{3+}, Ce^{3+}, Tb^{3+} phosphors were synthesized by high tempreture solid state method. The raw materials, $CaCO_3$(A.R.), $4MgCO_3 \cdot Mg(OH) \cdot 5H_2O$(A.R.), SiO_2(A.R.), Eu_2O_3(99.99%), Ce_2O_3(99.99%) and Tb_4O_7(99.99%), were mixed thoroughly in stoichiometric proportions, and heated in a temperature range of 950–1250℃ for 2-5h subsequently. Using the XRD study the crystal structure of the sample. The PL spectra of these phosphors were investigated by a Shimadzu, RF-5301PC spectrofluorophotometer. The surface morphology was investigated by a scanning electron microscopy.

Results and discussions

Fig.1 shows the SEM images of $Ca_2MgSi_2O_7$: Eu^{3+}, Ce^{3+}, Tb^{3+} phosphors which are calcined at different tempreture. The calcination temperature of a, b, c, d, is 950℃, 1050℃, 1150℃, 1250℃, respectively. These samples are all held for 4 hours. As shown in Fig.1a, when the calcining temperature is 950℃, the powders are anomalous small particles, the morphology is irregular and the interface between the small particles is not clear. As to 1050℃, the powders is mostly formed crystals, and powder particles distributed uniformly. It presents rules massive structure. But there is still finely particulate. When the calcining temperature rise to 1150℃, powders have clear interface, more complete morphology, smooth surface, and uniform size. While the powders are calcined at 1250℃, the prepared samples are severe adhesion and reunite, and the interface of the powders is not clear. It indicates that when the calcined temperature is too high, the crystal lattice will be cracked and crystalline phase will be liquefied. Therefore, the best sintering temperature is 1150 ℃.

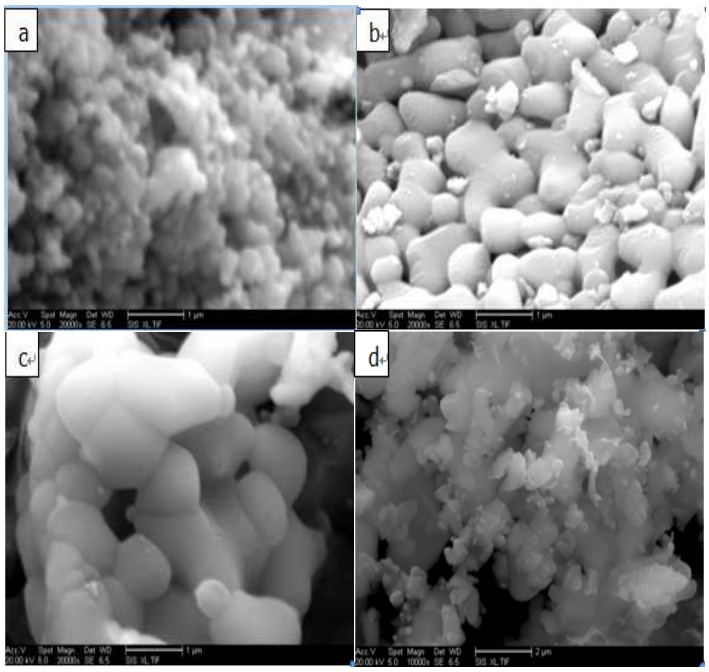

Fig.1 SEM images of $Ca_2MgSi_2O_7$: Eu^{3+}, Ce^{3+}, Tb^{3+} at different calcining temperature a)950℃, b)1050℃, c)1150℃, d)1250℃

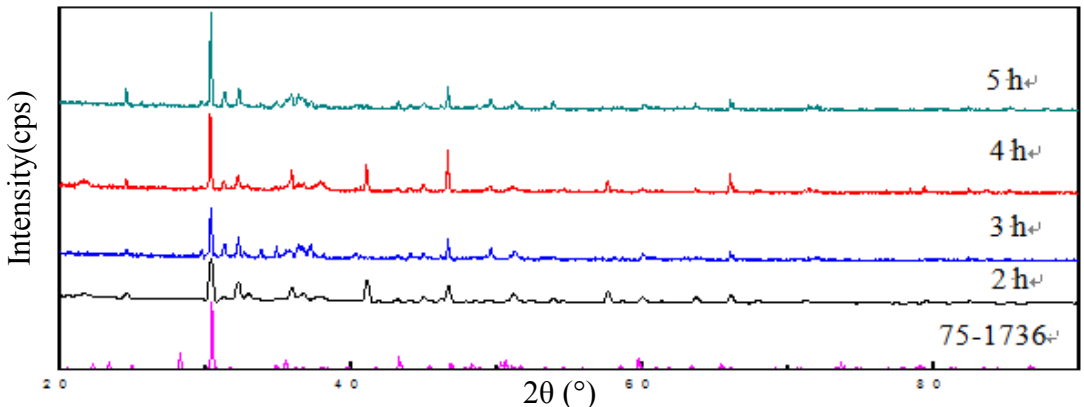

Fig. 2 XRD patterns of $Ca_2MgSi_2O_7$: Eu^{3+}, Ce^{3+}, Tb^{3+} which are held for 2, 3, 4, 5 hours

Fig. 2 shows the XRD patterns of $Ca_2MgSi_2O_7$: Eu^{3+}, Ce^{3+}, Tb^{3+} phosphors sintered for 2,3,4,5 hours. The diffraction peak positions and the relative intensities of the samples match well with the standard XRD patterns of $Ca_2MgSi_2O_7$: Eu^{3+}, Ce^{3+}, Tb^{3+} (PDF75-1736). It indicates that doping with

Eu^{3+}, Ce^{3+}, Tb^{3+} ions do not affect the crystal structure of $Ca_2MgSi_2O_7$. Synthetic samples are tetragonal system, and the space group is P421m(No.113). Diffraction peaks of prepared samples are obvious and relative sharp. With the holding time increased, sharpness of diffraction peaks is increasing and the half peak width is narrowed. When the calcination time is 4h, the diffraction peaks are the sharpest, the half peak width is the narrowest, and impurity peaks are the least. As the holding time further increased, the sharp diffraction peaks become diffuse, and the half peak width broaden. Even the holding time is increasing, the degree of crystallinity does not increase. Therefore, when the calcining time is 4 hours, luminescent material is the best in our experiment.

Curves a in the Fig.3 indicates that the phosphor can be excited by 393nm wavelength. In other words, the phosphor can be excited by NUV InGaN chip. Curves b ,c, d in the Fig.3 show the PL emission spectras of $Ca_2MgSi_2O_7$: Eu^{3+} with Eu^{3+} concentration of 0.5%, 1%, 1.5% when excited at 393nm wavelength. The PL emission spectra (Fig.3) exhibit the emission band peaks are located at 467nm, 588nm, 618nm, which are corresponding to the $^5D_2 \rightarrow {}^7F_0$, $^5D_0 \rightarrow {}^7F_1$, $^5D_0 \rightarrow {}^7F_2$ transitions of Eu^{3+} ion. With the concentration of Eu^{3+} ion further increased, emission peak positions do not change, but the emission intensity increases. When the concentration of Eu^{3+} reach 1%, the phosphors show the highest luminescent intensity. However, when the concentration of Eu^{3+} reach 1.5%, the luminescent intensity of the phosphors dropped. Therefore, the best concentration of Eu^{3+} is 1% in our experiment.

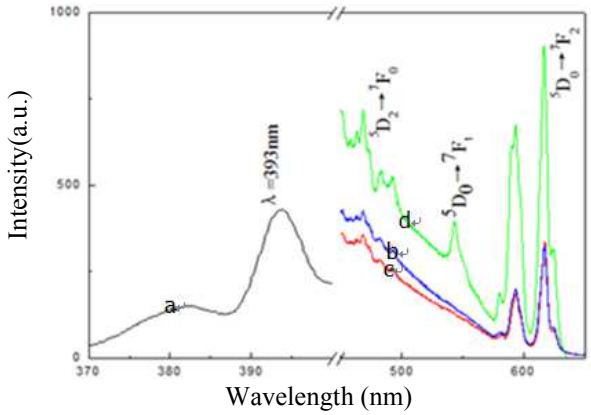

Fig.3 a) Excitation spectra of $Ca_2MgSi_2O_7$:Eu^{3+}, b) c) d) emission spectras of $Ca_2MgSi_2O_7$:Eu^{3+} ， concentration of Eu^{3+} are 0.5%, 1%, 1.5% .

Fig.4 shows PL emission spectrum of $Ca_2MgSi_2O_7$: Eu^{3+}, Ce^{3+}, Tb^{3+} with different doped ion concentration. Curves 1 presents the PL emission spectrum of $Ca_2MgSi_2O_7$: Eu^{3+}, Ce^{3+}, Tb^{3+} and the ratio of Eu^{3+}, Ce^{3+} and Tb^{3+} is 1:1:1.5. Curves 2 presents PL emission spectrum of $Ca_2MgSi_2O_7$: Eu^{3+}, Ce^{3+}, Tb^{3+} and the ratio of Eu^{3+}, Ce^{3+} and Tb^{3+} is 1:1:1. Curves 3 depicts PL emission spectrum of $Ca_2MgSi_2O_7$: Eu^{3+}, Ce^{3+}, Tb^{3+} and the ratio of Eu^{3+}, Ce^{3+} and Tb^{3+} is 1:1.5:1. As we can see from Fig.4, the blue and green emission peak decreased with the concentration of Ce^{3+} reducing, because the reducing concentrations of Ce^{3+} which make transmission of energy between Ce^{3+} and other rare earth ions reduce. When the concentration of Ce^{3+} reduced and the concentration of Tb^{3+} increased, the green emission peak significantly enhanced and the red emission peak significantly decreased. It made luminescent material emits green light instead of white light which we want. In this experiment, the best ratio of Eu^{3+}, Ce^{3+} and Tb^{3+} is 1:1.5:1

All the results calculated from the spectra is plotted in the CIE 1931 chromaticity diagram, as shown in Fig.5. When $Ca_2MgSi_2O_7$ doped with Eu^{3+}, Tb^{3+}, Ce^{3+}, the piont was located at (0.340,0.314). It indicates that $Ca_2MgSi_2O_7$: Eu^{3+}, Tb^{3+}, Ce^{3+} is close to the edge of CIE diagram, which indicates this phosphor emit white light.

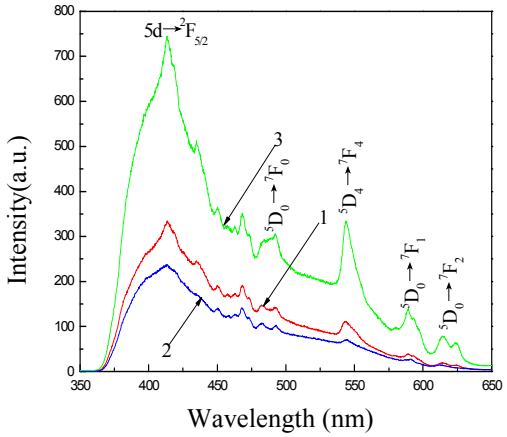

Fig.4 Emission spectras of $Ca_2MgSi_2O_7$ Eu^{3+},Ce^{3+},Tb^{3+}.

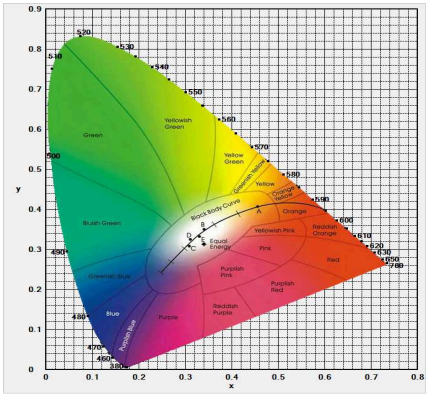

Fig.5 CIE chromaticity diagram of $Ca_2MgSi_2O_7$: Eu^{3+}, Ce^{3+},Tb^{3+}.

Conclusion

In summary, we have successfully prepared a new white $Ca_2MgSi_2O_7$: Eu^{3+}, Ce^{3+}, Tb^{3+} phosphor synthesized by the solid-state reaction. XRD results indicate the prepared phosphor is tetragonal structure. It possesses an ideal spectral feature, which has five main peaks located at 413nm, 492nm, 543nm, 588nm, 614nm. The best molar ratio of Eu^{3+}: Ce^{3+}: Tb^{3+} was set to 1:1.5:1. The CIE coordinates of phosphors can be adjusted by controlling the rare earth ions concentration. The obtained results indicate that $Ca_2MgSi_2O_7$: Eu^{3+}, Ce^{3+}, Tb^{3+} phosphor could be further investigated for its potential application on near-UV excitable WLEDs.

Keywords: Fuzzy PID control.Smith predictor control.Chloroacetic acid.

Abstract. Based on detailed analysis of crystal process in Chloroacetic Acid(MCA)'s production, a certain control method is exert on it. In order to overcome the time delay ,large inertia, time-varying ,a fuzzy Smith intelligent method is proposed.Simulation results show that this method apparently is superior to the general PID control and Smith control.

Introduction

Adopt method of cooling crystallization in MCA's production,and most of the factories adopt to mixed water in the preheating tank into crystallization reactor jacketed for the material cooling of the reactor.The temperature control of preheating tank need to strictly change according to certain rules[1] .Based on fully understand MCA's crystallization process,design a rational control scheme.Because the preheating tank has the disadvantages of time delay ,large inertia, time-varying,its control effect is often not satisfactory . Therefore, it is very important to seek an effective and accurate method to control the temperature of preheating tank , a fuzzy Smith intelligent method is proposed.Simulation results show that the method can improve the robustness and steady-state accuracy of system.

Crystallization Process and Control Requirements in MCA's Production

Because melting point of different material is different , separate dichloroacetic acid from MCAby method of cooling crystallization[2].According to the process flow diagram of MCA crystallization ,reasonable control scheme is put forward which is shown in Fig. 1.

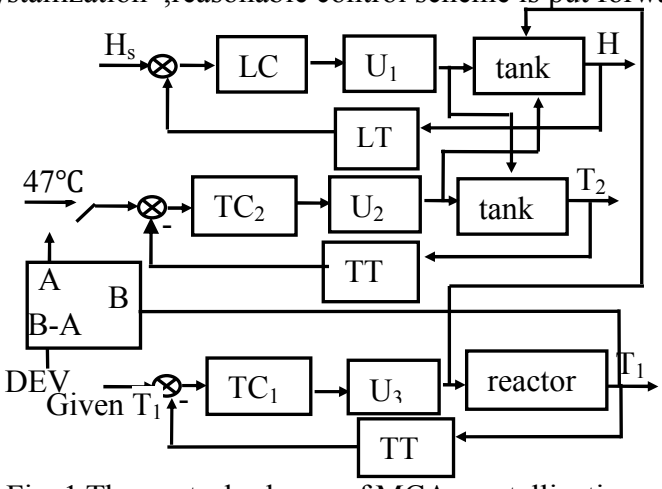

Fig. 1 The control scheme of MCA crystallization

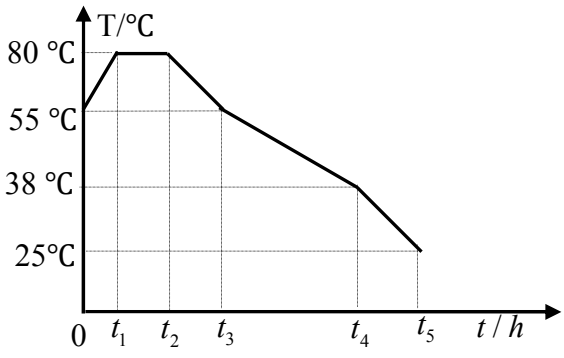

Fig. 2 Material temperature change curve

Crystal process in MCA's production is divided into fifth stages.The temperature variation trend of the material in the crystallization reactor is shown in Fig. 2 .

The first stage($0-t_1$): two-way switch is off,the switch control (LC) 100 ℃hot water to make liquid evel of preheating tank does not exceed the limit .The reactor temperature T1 is given as 80 ℃ make the material quickly heated to 80 ℃.Because of temperature lag,when the reactor temperature

reached 79 ℃, two-way switch connected to given 47 ℃, adjusting the cold water valveU2 for the preheating tank temperature is decreased.Hot water valveU1 opening degree is 40% by manually adjust the valve plug.Like this, not only ensure the accuracy of the temperature, but shorten the crystallization time .

The second stage($t_1 - t_2$):there is a certain amount of hot water in the tank,even if it is injected -15 ℃ cold water, the tank temperature does not drop rapidly .So the temperature of reactor was maintained at 80 ℃, until the temperature of the preheating tank drops to 80 ℃.

The third stage($t_2 - t_3$): there is no crystal production at this stage, so the reactor temperature may drop slightly faster.The preheating tank temperature constant at 47 ℃.The reactor temperature is drop at a rate of 10 ℃/h , until it is decreased to 55 ℃, and then adding crystal seed(0.5kg/m³)[3].

The forthstage($t_3 - t_4$):it is produces a lot of crystals,so the reactor temperature is decreased slowly in case it produce knot wall.At this time two-way switch is turned subtractor, the temperature of preheating tank with the reactor temperature strict control T1-T2 = 8 ± 0.5 ℃, DEV = 8 ± 0.5 ℃.The reactor temperature is drop at a rate of 5 ℃/h , until it is drop to 38 ℃.

The fifth stage($t_4 - t_5$):This stage is not required to consider knot wall phenomenon, the reactor temperature can drop faster.Preheating tank temperature with the temperature of reactor control T1-T2 = 14±2℃.The reactor temperature is drop at a rate of 10℃/h , until the reactor temperature is decreased to 25℃ which to prevent pipe blockage due to temperature fluctuations.

The Temperature Control System for Preheating Tank

The algorithm of improved-type Smith predictor

Smith predictor controller [4]is a algorithm which forecast estimated compensation time lag.In order to overcome the shortcomings of the model error sensitive, C.C.Hang propose an improved-type Smith predictor is shown in Fig. 3.

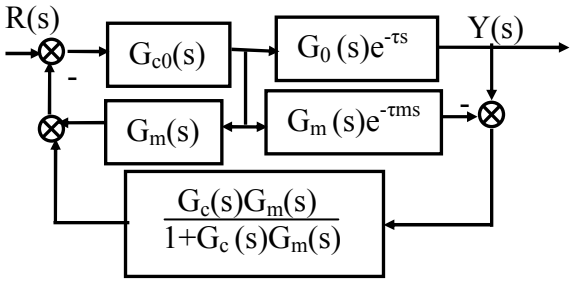

Fig. 3 The structure of the improved-type Smith predictor

It differs from the method of Smith control is more a regulator which feed back transfer function:

$$G_f(s) = \frac{G_c(s)G_m(s)}{1 + G_c(s)\mathrm{G}_m(s)} \tag{1}$$

where, G_c(s) is a PI regulator, G_m(s) is a first-order inertia, regulator integral time constant equal to the time constant of the model, Eq. 1 can be simplified as:

$$G_f = 1/t_f s + 1 \tag{2}$$

Closed loop system transfer function:

$$\frac{Y(s)}{R(s)} = \frac{G_{c0}(s)G_0(s)e^{-\tau s}}{1 + G_{c0}(s)\mathrm{G}_0(s) + \mathrm{G}_{c0}(G_0(s)e^{-\tau s} - G_m(s)e^{-\tau s})\dfrac{1}{t_f s + 1}} \tag{3}$$

Obviously, the improved method is the same with the original Smith predictor which has no effect on the stability of the system,when $G_m(s) = G_0(s), \tau_m = \tau$ .Even if there is an error, as long as appropriate adjustments t_f , Control effect of the system is better.In this paper, the t_f of improved-type Smith predictor is designed by fuzzy control[5].

Design on fuzzy Smith intelligent controller

Fig. 4 shows the structure of the fuzzy Smith intelligent controller for temperature control of preheating tank.

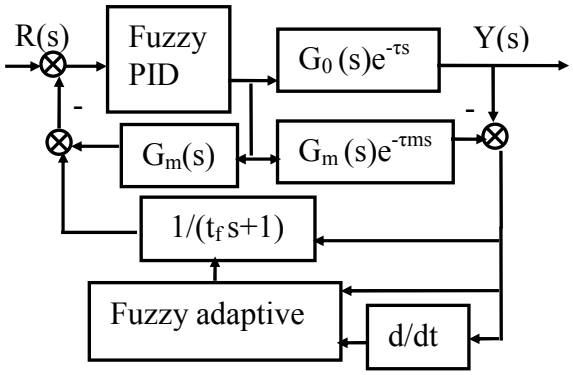

Fig. 4 The structure of the fuzzy Smith intelligent controller

In this paper, t_f is adjusted by fuzzy adaptive mechanism .The error t_e of object output and Smith Predictor output and change in error Δt_e are chosen as inputs to the fuzzy controller, Δt_f is chosen as outputs to modify the parameters t_f . t_f is calculated as follows:

$$t_f(k) = t_f(k-1) + \Delta t_f(k) \tag{4}$$

In order to enhance the robustness of the system , t_f can't be negative which given a minimum.Based on experience, and generally the minimum is $T/4 - T/3$. Δt_f is defined as {-6, +6}, the fuzzy set is {NB，NS，ZO，PS，PB}. The membership function defined as Triangular distribution.

Firstly,setting of t_f to determine the fuzzy control rule. $|\Delta t_e|$ will be large when controlled objects lag time and lag time of predictor are different,but the time constant and the magnification change will not have large $|\Delta t_e|$ .If $|t_e|$ is not too large,and is close to a constant value, it indicates that magnification of controlled objects is charged .Then inertia should not be introduced, should make t_f = 0. Adjusted trend of t_f rely on analysis $|\Delta t_e|$,if it is difficult to determine which parameters change.when $|\Delta t_e|$ is large,need to increase t_f to enhance the stability and robustness of the system;while $|\Delta t_e|$ is small,need to be reduced t_f in order to enhance rapid system.

Based on the above approach of tuning t_f and the past experiences, the control rules for output variables Δt_f is listed in Tables l .

Table 1 The fuzzy rule of Δt_f

Δt_f	Δt_e				
	NB	NS	Z0	PS	PB
t_e	NB PB	PB	PS	PS	PB
	NS PS	NS	NS	Z0	PS
	Z0 PS	Z0	Z0	PS	PS
	PS PS	Z0	NS	PS	PS
	PB PB	Z0	NS	PS	PB

System Simulations and Analysis

The temperature control of preheating tank can be expressed by a time delay plus an inertia input.,the model can be written as the following equation.

$$G(s) = \frac{5.3}{900s+1} e^{-90s} \tag{5}$$

The comparison of simulation results for fuzzy Smith intelligent control , PID control , Smith control are shown in Fig. 5,andFig. 6,respectively,when the model is accurate, the gain K ,the time constant T and the lag time τ are change.The control quality and the robustness of this system apparently are superior to the PID system,especially when model parameters are little uncertain.

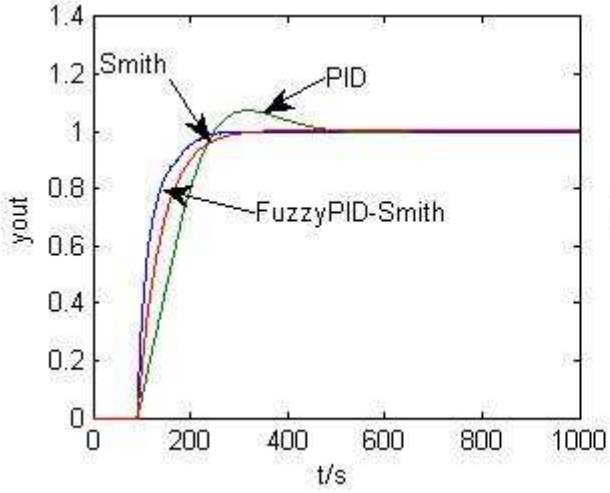

Fig. 5 Simulation results of accurately model

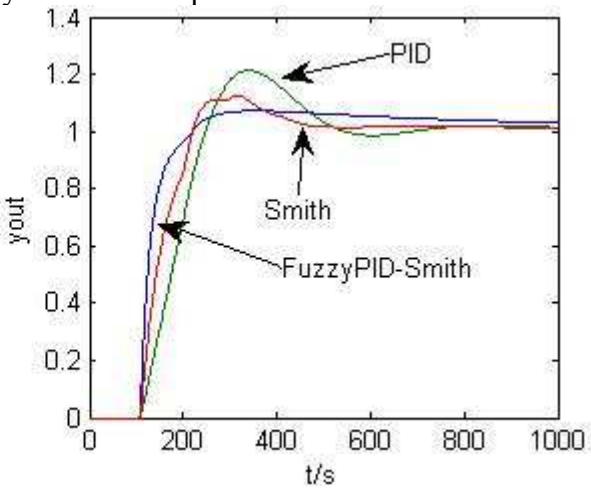

Fig. 6 Simulation results of parameters change

Summary

It is design a rational control schemer for crystal process in MCA's production.In order to solve the control difficulties for preheating tank with long time-delay, large inertia, time-varying ,a fuzzy Smith intelligent control method is proposed in this pape. Combined the fuzzy Smith intelligent control, PID control, with Smith control, this method has improved the dynamic performance of the system, eliminated the steady-state error, and has good adaptability when system model changes.

Keywords: Electroless plating; Ni-Sn-P alloy; $SnCl_4$; Alloy properties

Abstract. In this paper, the influence of $SnCl_4$ concentration on deposition rate, tin content, corrosion resistance and surface appearance of the coating are researched respectively. The results show that $SnCl_4$ concentration is increased, deposition rate is increased, then reduced. Tin content in the Ni–Sn–P coatings is increased with increasing $SnCl_4$ concentration in the solutions. However, Ni and P contents in the coating is decreased slightly. The microhardness of plating before and after heat treatment is above 500HV. The hardness will be improved a little after heat treatment. With increasing $SnCl_4$ concentration, the polarization curves slightly move to positive direction and decrease corrosion current, which shows that the introduction of tin tends to enhance resistance corrosion of the coating. When $SnCl_4$ concentration is up to 30g/L, resistant corrosion of the films presents a drop various degrees. The deposits is smooth and uniformity, smooth by SEM and the content of tin is 2.5 to 4.1 percent by EDS.

Introduction

Today the attention to the electroless plating of nickel-based ternary alloys[1-4] has been increased, one of which is Ni-Sn-P alloy. Ni-Sn-P coating has anticorrosion behavior, solderability, better decoration, and so on. Its industrial application is expanding too, such as spaceflight, building, chemical industry, machinery. Because tin has not selfcatalysis, tin ion is regarded as toxic reagent in electroless plating. It can decease the deposition rate, even make it difficultly form coating. So $SnCl_4$ concentration in baths directly affects the tin content, quality, properties of coating. Though a lot of reports [5-7] on this subject and relevant studies have been published, high quality alloy film of Ni-Sn-P obtained should be studied further.

The aim of this review is to obtain good quality of Ni-Sn-P. The effects of $SnCl_4$ concentration in baths on the deposition rate, hardness, corrosion resistance of the deposits is presented. Further -more, the surface morphology and composition of the deposits have also been studied.

Experimental

Sample preparation

Shown in Table 1 are the bath compositions and the operating conditions for the electroless deposition of Ni-Sn-P alloys. $SnCl_4$ concentration in bath is 10g/L, 15g/L, 20g/L, 25g/L, 30g/L, 35 g/L, respectively. All solutions used were freshly prepared using analytical grade chemicals and double-distilled water. Iron samples in a rectangle shape with dimensions of 40mm×15mm×1mm were chosen to be plated. The pre-treatment process of iron substrates is as follows. First, Fe substrate was consecutively degreased in a solution containing 40g/LNa_3PO_4, 40g/L Na_2CO_3 and 30g/L NaOH at 70℃ for 4min, rinsed with deionized water. Secondly, the samples were immersed in hydrochloric acid(hydrochloric acid: water in terms of volume is 1:1) for 30 seconds at room temperature and rinsed with deionized water.

Table1 Bath composition and operating conditions for electroless deposition of Ni-Sn-P alloys

Component	*Values apdoted*
$NiSO_4 \cdot 6H_2O$	30g/L
$C_3H_6O_3$	32.5g/L
$C_4H_4O_6KNa \cdot 4H_2O$	7.5g/L
$C_6H_5Na_3O_7 \cdot 2H_2O$	17.5g/L
$C_4H_6O_4$	16g/L
$NaH_2PO_2 \cdot H_2O$	30g/L
A addition	appropriate amount
pH	5.0
Temperature	90℃
Plating time	1h

The surface morphology and composition of the coating were observed and analyzed with SEM and EDS. The Vicker hardness (Hv) was measured with digital micro-hardness(MH-3), which test-condition is a 0.5N force for 10s. Corrosion test is conducted in 5%NaCl solution with CHI660C electrochemical workstation, which is the plating film as working electrode, high purity graphite works as auxiliary electrode, and saturated calomel electrode (SCE) as reference electrode. The surface of the working electrode is $1cm^2$.

Results and discussion

Effects of $SnCl_4$ concentration on deposition rate and composition of coatings

The effects of $SnCl_4$ concentration in plating solutions on the deposition rate of Ni-Sn-P and its compositions are illustrated in Fig.1 and 2, respectively. Fig.1 shows that deposition rate increases, then decreases with increasing $SnCl_4$ concentration in the solution for a given pH and a given temperature. When $SnCl_4$ concentration is 25g/L, deposition rate is up to $0.098mg \cdot mm^{-2} \cdot h^{-1}$.It is due to the fact that as reactive ion, Sn^{4+} concentration rising is beneficial to improve depositing reaction rate. At the same time, electrode potential of Sn^{4+}/Sn will rise with increasing Sn^{4+} concentration, which is conducive to tin ion deposited. But if $SnCl_4$ concentration was too high, deposition rate is lowered, which is because of tin being not selfcatalysis. Fig.2 shows that tin content in the Ni–Sn–P coatings is increased with increasing $SnCl_4$ concentration in the solutions. However, Ni and P contents in the coating is decreased slightly.

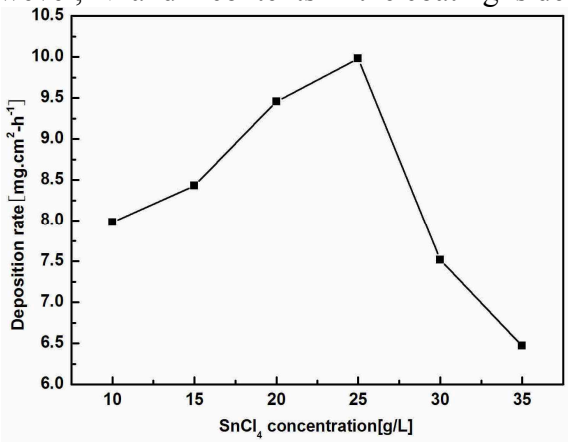

Fig.1 Effect of $SnCl_4$ concentration on deposition rate

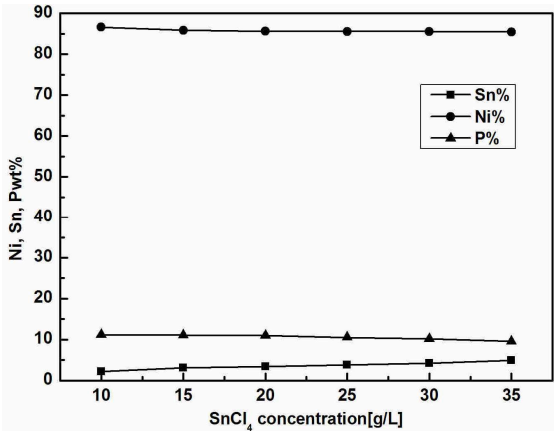

Fig.2 Effect of $SnCl_4$ concentration on coating composition

Effects of $SnCl_4$ concentration on the morphology of the coatings

Fig.4 shows the SEM photograph of the coating surface obtained with different $SnCl_4$ concentration. As showed in Fig.4, the Ni-Sn-P deposits have cell-shaped structure. With increasing $SnCl_4$ concentration, cellular granular of deposits became finer, more homogeneous and rounder, which led to obtaining the film being uniform, compact, and smooth. But if $SnCl_4$ concentration is over

30g/L, the deposits quality has fallen only slightly. Possibly because deposition potentials of Sn^{4+} is greater than that of Ni^{2+}, depositing preferentially tin is bad for depositing Ni and results in organizational segregation. The cells in deposits becomes bigger, as showed as in Fig.3f.

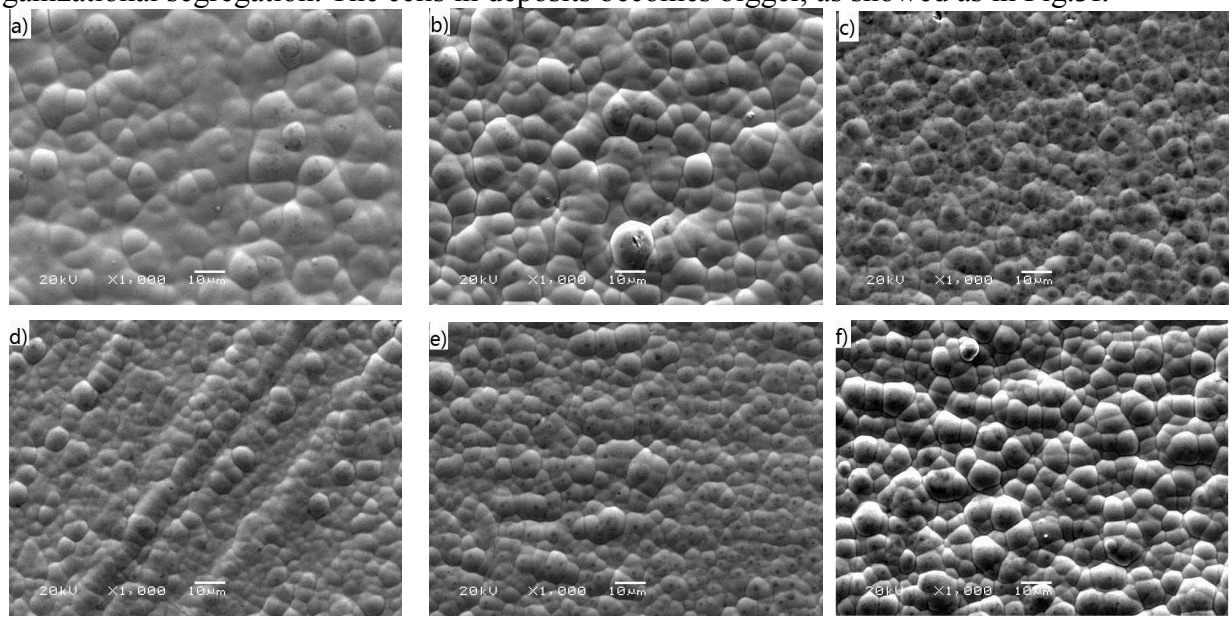

Fig.3 SEM of the film surfaces obtained with different $SnCl_4$ concentration in the solution(a:10g/L $SnCl_4$;b:15g/L$SnCl_4$; c:20g/L $SnCl_4$; d:25g/L$SnCl_4$; e:30g/L $SnCl_4$; f: 35g/L $SnCl_4$)

Effects of $SnCl_4$ concentration on hardeness of deposits

Fig. 4 shows the hardness value (Hv) of the Ni-Sn-P deposit. It is showed that the hardness of the deposits before and after heat treatment are increased, then declined with ascending $SnCl_4$ concentration. Investigated its reason, deposition rate is improved with raising $SnCl_4$ concentration and then the coating thickness increases, as well as the deposit sites grow in number, which causes that the celluar deposited particles become smaller and the film thickness also increases. These makes the deposit hardness increase with raising $SnCl_4$ concentration. However, the deposits quality is deceased when $SnCl_4$ concentration exceeds a specific value, which results in declining the hardness. After heat treatment, new phases in the deposits, such as Ni_3P, Ni_3Sn, have higher hardness and a function of precipitation hardening, improves the resistance of plastic deformation, which leads increasing hardness of deposits after heat treatment.

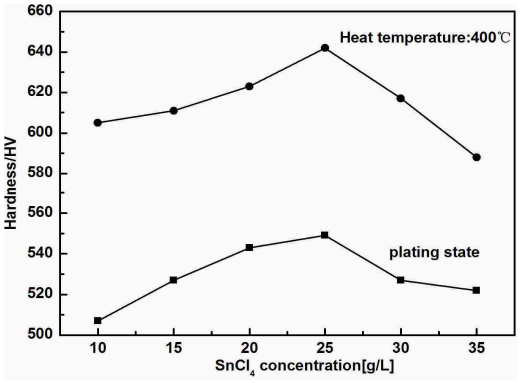

Fig.4 Effect of tin concentration on deposits hardness before and after heat treatment

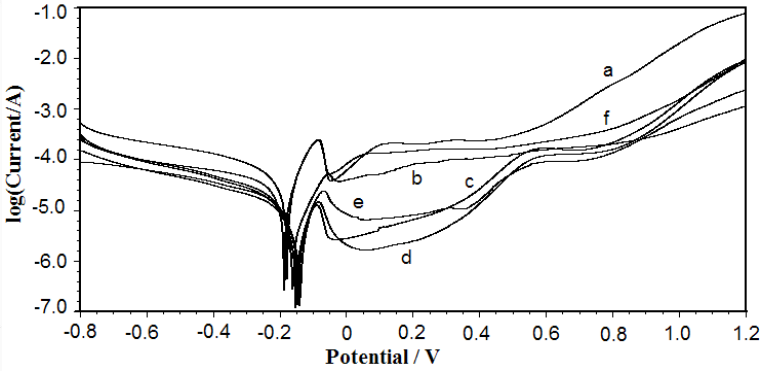

Fig.5 Anodic polarization curves of coatings in 3.5% NaCl solution(a:10g/L$SnCl_4$;b:15g/L$SnCl_4$; c: 20 g/L $SnCl_4$; d:25g/L$SnCl_4$; e:30g/L $SnCl_4$; f:35g/L $SnCl_4$)

Effects of $SnCl_4$ concentration on anticorrosion coating

Fig.5 showed the anodic polarization curves of the coatings in 3.5%NaCl solution. Free corrosion potential and corrosion current of deposits plating state are showed Table 2. As showed in Fig.5 and Table 2. Free corrosion potential varies from -0.187V～-0.138V and free corrosion current ranges from 3.758 e^{-6}～4.998e^{-5}A·cm^{-2}. And these increase firstly and then decrease and show the same trends with deposition rate. With increasing $SnCl_4$ concentration, the polarization curves slightly

move to positive direction and decrease corrosion current, which shows that the introduction of tin tends to enhance resistance corrosion of the coating. Because tin in the films played a sacrificial anode role in corrosion process, their base alloys were effectively protected, resistance corrosion of Ni-Sn-P alloy is improved[8]. When $SnCl_4$ concentration up to 30g/L, the deposits quality is deceased and resistant corrosion of the films presents a drop various degrees.

Table 2 Free corrosion potential and corrosion current of deposits plating state

$SnCl_4$ g/L	E(vs SCE)V	Current/A
10	-0.187	$4.998\times e^{-5}$
15	-0.161	$1.019\times e^{-5}$
20	-0.144	$4.454\times e^{-6}$
25	-0.138	$3.758\times e^{-6}$
30	-0.15	$7.556\times e^{-6}$
35	-0.177	$6.116\times e^{-6}$

Conclusions

Ni-Sn-P alloy with different Sn content are prepared by electrless plating. The results show that with increasing $SnCl_4$ concentration in baths, the deposition rate, hardness, resistance corrosion of the coating show an upward trend. If $SnCl_4$ concentration is too higher, the above will be decreased. After heat treatment, the hardness will be improved a little. The deposition rate tops $9.98mg\cdot cm^{-2}\cdot h^{-1}$, the hardness is above 500Hv, and the highest corrosion current is $4.998e^{-5}$. The content of tin is 2.5 to 4.1 percent in the coatings. Ni-Sn-P alloy the surface morphology of deposits is cystiform structure, smooth, the grain of crystal and good properties.

Application of Environmental Rubber in Concrete Road Engineering

Rui Yang

JiangSu Jianzhu Institute, Xuzhou, 221116,China

Keywords: Environmental rubber; ANSYS software; Numerical simulation; Ultimate bearing capacity; Secondary development; New materials

Abstract. Environmental rubber concrete is a new building material, which can improve the construction quality of road drainage tube in road engineering and achieve effect of keeping warm and radial anti deformation. In order to study the physical properties of environmental rubber concrete, we use methods of experiment and numerical simulation to test mechanical parameters and effect of thermal insulation of concrete. Through the experiment we obtain the relation between ultimate bearing capacity and temperature. We use the software of ANSYS to secondary development on c numerical calculation, and establish a mathematical model of road drainage tube. Through the numerical simulation we get the temperature distribution and the radial strain nephogram of environmental rubber concrete. It provides a new method to study new materials in road engineering.

Introduction

Environmental rubber concrete is a new building material, due to the double mechanical properties of concrete and rubber, which makes the mechanical properties of the material complicated. ANSYS is professional structural analysis software, which is widely used in the strength calculation and analysis in road engineering [1,2]. In this paper we compare the results of experiment and numerical simulation to study the mechanical properties of rubber concrete[3,4]. The basic process is shown in Figure 1.

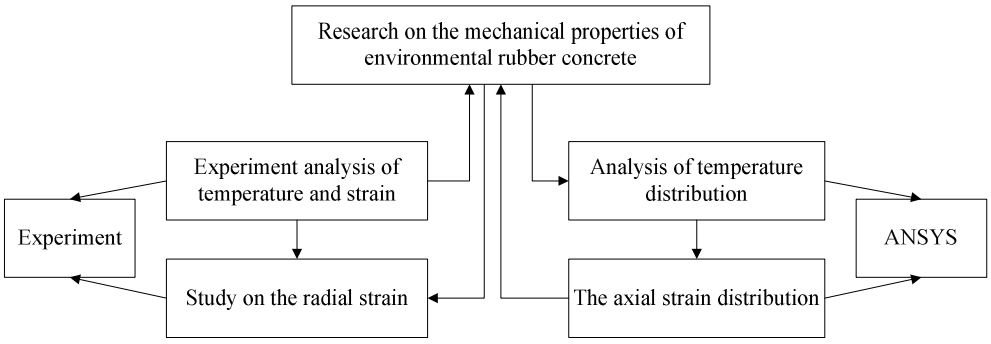

Fig. 1 Flow chart of road environmental rubber concrete

Mathematics Model of Rubber Concrete Road Drainage Pipe and the Design of ANSYS Algorithm

We use mechanics of structure and material to study the mechanics properties of rubber concrete drainage pipeline, and establish reasonable stress and strain model [5, 6]. Assume that the strain of pipeline is *0*, namely $\gamma_{xz}=0,\gamma_{xz}=0$. So the geometric equation can be written as:

$$\begin{cases}\dfrac{\partial b}{\partial z}+\dfrac{\partial c}{\partial y}=0\\ \dfrac{\partial a}{\partial z}+\dfrac{\partial c}{\partial x}=0\end{cases}. \tag{1}$$

If $(a)_{z=0}=0$, $(b)_{z=0}=0$, so we can get:

$$a=-z\frac{\partial c}{\partial x}, b=-z\frac{\partial c}{\partial y}. \tag{2}$$

The three stress zero point in drainage pipe can be written as the partial differential equations as shown in the formula (3).

$$\begin{aligned}\delta_x &= \frac{\partial a}{\partial x}=-z\frac{\partial^2 c}{\partial x^2}\\ \delta_y &= \frac{\partial b}{\partial y}=-z\frac{\partial^2 z}{\partial y^2}\\ \lambda xy &= \frac{\partial a}{\partial y}+\frac{\partial b}{\partial x}=-2w\frac{\partial^2 c}{\partial xy}\end{aligned} \quad . \tag{3}$$

If the value of σ_w can be neglected, the expression of drainage pipe strain can be written as shown in formula (4).

$$\begin{aligned}\delta_x &= \frac{\sigma_x}{E}-\lambda\frac{\sigma_y}{E}\\ \delta_y &= \frac{\sigma_y}{E}-\lambda\frac{\sigma_x}{E}\\ \delta_{xy} &= \frac{2(1+\lambda)}{E}\tau_{xy}\end{aligned} \quad . \tag{4}$$

The stress components can be expressed as:

$$\begin{aligned}\sigma_x &= -\frac{E}{1-\lambda^2}z\left(\frac{\partial^2 c}{\partial x^2}+\mu\frac{\partial^2 c}{\partial y^2}\right)\\ \sigma_y &= -\frac{E}{1-\lambda^2}z\left(\frac{\partial^2 c}{\partial y^2}+\mu\frac{\partial^2 c}{\partial x^2}\right)\\ \tau_{xy} &= -\frac{E}{1+\lambda}c\frac{\partial^2 c}{\partial xy}\end{aligned}. \tag{5}$$

After establishing the stress-strain mathematical model of environmental concrete drainage pipe, we can use ANSYS command stream to develop the model of tress-strain. The main program of command stream is as follows:

Study on the Performance of Rubber Concrete Experiment and Numerical Simulation

In order to verify the effectiveness and reliability of strain-stress mathematical model and the structural analysis algorithm designed in second part, we use the method of materials mechanics and ANSYS numerical simulation to study the performance of rubber concrete materials [7, 8]. By comparing the results of experiment and numerical simulation, it verifies the accuracy of the model.

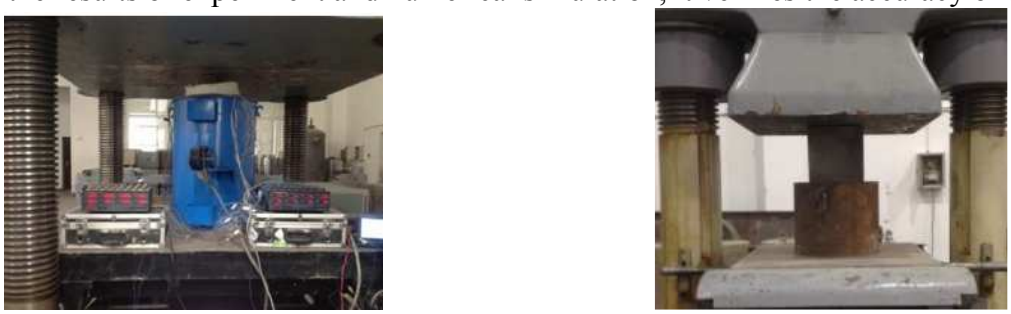

Fig. 2 Experiments of temperature and the tensile

Figure 2 shows studying the mechanical properties of rubber concrete materials by step loading at different temperatures, finally we get the ultimate bearing capacity bearing capacity of rubber concrete materials under different temperature conditions. The results are as shown in Table 1.

Table 1. Results of ultimate bearing capacity

No.	Temperature ($^{\circ}C$)	Ultimate bearing capacity (t)
1	10	185.2
2	20	177.3
3	30	165.8
4	40	158.2

Table 1 shows ultimate bearing capacity of rubber concrete. From the table we can see, the ultimate bearing capacity is different under different temperature, and along with the temperature increasing it gradually decrease. In order to increase the reliability of experimental data, we use ANSYS to do numerical calculation on the mechanical properties of rubber concrete. Firstly we establish mathematical model of drainage tube in road engineering, and modify the model name, do grid division. The structure grid is as shown in Figure 3.

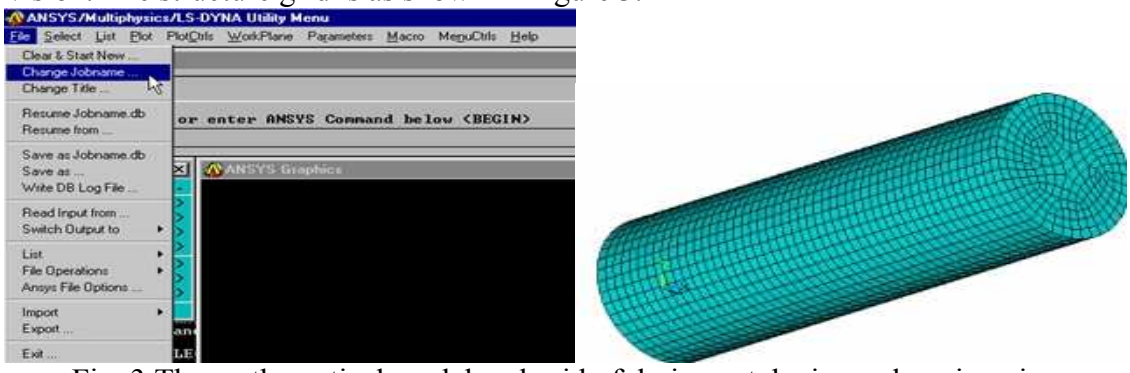

Fig. 3 The mathematical model and grid of drainage tube in road engineering

As shown in Figure 3, after establishing the mathematical model of drainage pipeline we can set the pretreatment process of numerical simulation. The pretreatment includes materials set, boundary conditions loading and calculation initialization. Through calculation we can use Figure 4 to view the ANSYS operation results.

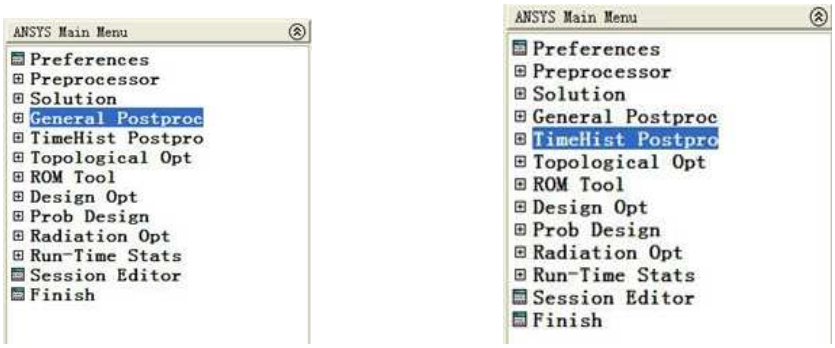

Fig. 4 View window settings of ANSYS calculation result

Figure 4 shows the view setting of ANSYS calculation results. First entering the general-purpose processor or time series processor, we use cloud view, curve drawing and form drawing to display the results [9]. Through the numerical simulation we get the temperature distribution of drainage pipe as shown in Figure 5.

Figure 5 shows the temperature distribution of drainage obtained in road engineering by ANSYS numerical simulation [10]. From it we can see, in the protection of outer rubber concrete layer, heat preservation effect of pipeline is good, tube inside temperature is delaminating and maintains a certain number of value.

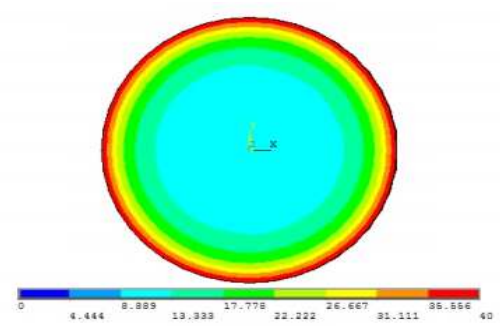

Fig. 5 Temperature nephogram of concrete pipe

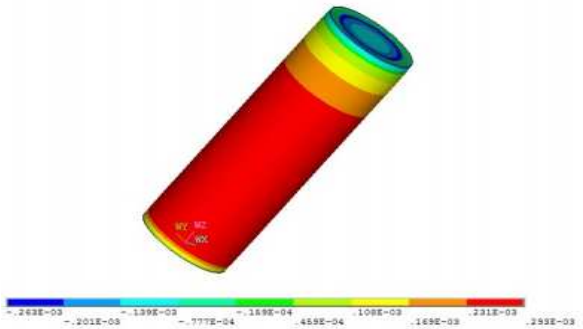

Fig. 6 The radial strain of pipeline

Figure 6 shows the radial stress distribution of road drainage pipe calculated by ANSYS software. From it we can see the radial strain of pipeline is mainly concentrated in the external, internal stress is small, which shows that the rubber concrete protects pipeline effectively and the internal strain of pipeline is reduced to a minimum.

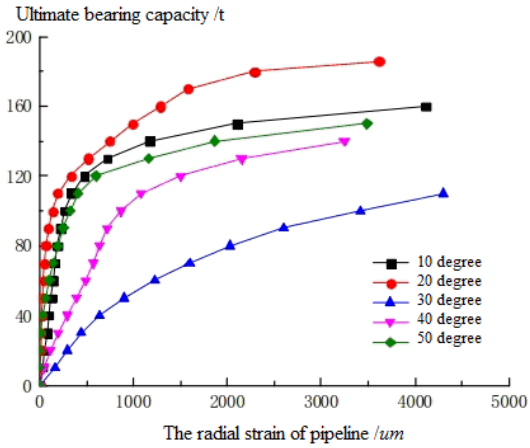

Fig. 7 The calculation results of strain changing with temperature

Figure 7 shows the ultimate bearing capacity curve of the pipeline obtained by ANSYS numerical simulation [11]. From the curve we can see, with the increase of temperature, ultimate bearing capacity of rubber concrete decreases, this is because that the changing temperature changes the mechanical properties of rubber. The numerical results are consistent with the experimental results.

Summary

In this paper we use the experimental methods to test the mechanical properties of environmental rubber, establish mathematical model of rubber concrete, and obtain the mechanical properties curve changing with time by experiment. We use the command stream programming to do secondary development on the performance of ANSYS software, and establish numerical simulation model of road drainage tube. Through the numerical simulation we calculate the temperature distribution and the radial strain nephogram of environmental rubber concrete. By comparing the results of experiment and numerical calculation we obtain the stress-strain nephogram, ultimate bearing capacity changing with time. We find the ultimate bearing capacity decreases with the increase of temperature, and the experiment is consisted with numerical simulation.

Keywords: hot water extraction; corncob hemicelluloses; composite films

Abstract. In this study, corncob hemicelluloses were extracted by hot water to investigate its potential for film production. Extracted hemicelluloses were mixed with PVA 30 wt%, the prepared films had a smooth, uniform and continuous surface and dense cross section without the phase separation, as characterized by SEM. Besides, the mechanical properties and thermal characteristics tests showed that the films had a tensile strength of 4.6 MPa, elongation at break of 6.4%, and a nice thermally stability.

1. Introduction

Corn planting area in China is widely distributed: northeast, north China, northwest, southwest and southeast etc. Correspondingly, more than ten million tons of corncobs are generated in China every year[1]; these agricultural wastes are renewable, costless and widespread sources of chemicals. But in most cases, the lignocellulosic materials are left unutilized in harvested fields, burned for instance, which not only is an application with low added value but also can cause various environmental problems such as soil and water erosion.

There are many pre-extraction methods of hemicellulose , such as the physical, chemical or biological. As a physical method, hot water treatment shows some unique advantages over others: The whole process is environment-friendly for the reaction media is water and no chemicals, so the corrosion problems are avoided and no specific requirements for equipment[2]. Besides, process structure is simple due to get rid of handling neutralization sludges[3]. In brief, the utilization of hot water method to extract hemicellulose from biomass has broad application prospects. In recent years, increasing studies about the utilization of hemicellulose from agricultural biomass as new films are reported, due to the fact that these feedstock are from renewable and less expensive sources[4]. The hemicellulose films are environmentally friendly, and also naturally biodegradable[5]. It has wide range of potential applications in food packaging and other fields. However, the pure hemicellulose films have some problems in mechanical property. Addition of reinforcing agent and plasticizer can improve the film properties and transfer this potential into reality. Sárossy et al.[6] added sepiolite as reinforcing agent and poly (ethylene glycol) methyl ether (mPEG) plasticizer to rye flour arabinoxylan to enhance the properties of the composite films, and mechanical testing showed increases in film stiffness and strength with the above two additives addition. in order to

develop composite films with corncob hemicellulose and some new reinforcing agent and plasticizer, corncob hemicelluloses were extracted by hot water, then the films on structure, surface and mechanical properties were characterized.

2. Experimental

2.1 Raw material

Corncob were produced in east China, It was first dried in sunlight and then cut into small pieces (2~3 cm), and then the small pieces were milled into 0.18~0.85 mm particle size by a mill, air-dried again and stored until use.

2.2 Analysis of corncob

To analysis of corncob chemical components, the sample was subjected to acid hydrolysis sequentially with 72% and 4% sulphuric acid following standard methods[7]. The compositions of the corncob (%, w/w) are as follows: extract 4.10%, ash 2.15%, Klason lignin 12.50%, acid soluble lignin 1.43%, glucan 32.76%, xylan 34.90%, arabinan 1.08%, and acetyl groups 3.52%.

2.3 Pre-extraction of hemicellulose from corncob

Milled corncob samples and water were mixed in 250mL Parr reactor with the proportions of 1:14 (w/w). The reactor was then sealed and heated to 170 ^{o}C and final temperature was held for 30 min. After the extraction, the liquor were separated by filtration and concentrated to about 50mL under reduced pressure. Sequentially about 150 mL ethanol was added to the concentrated filtrates slowly at room temperature under constant stirring. The precipitated hemicelluloses were recovered by centrifugation, washed with 70% ethanol and freeze-dried.

2.4 Film casting

The ratios of the three components (corncob hemicelluloses, PVA, sorbitol) in composite films were 100:10:10, 100:20:10 and 100:30:10. The solution concentration was 10%. Corncob hemicellulose and sorbitol were mixed with distilled water for 1h at 90 °C under magnetic stirring, and then mixed with PVA solution dissolved in hot water. The film-forming solution was prepared under the heating and stirring at 90 °C for another 1h. Then, the film-forming solution was poured into a Teflon plate. The films were then left to dry under normal room conditions (23 °C, RH 50%) for two days and finally conditioned in a desiccator over magnesium nitrate hexahydrate for a minimum of 48 h prior to analysis.

2.5 Analytical methods

The film thickness was measured by using an Electronic Vernier caliper. The tensile strength and breaking elongation of films were measured using a Universal Testing Machine with a 20N load cell, the films strips were stretched at 20 mm x 6 mm. Microstructure analysis was conducted on a Hitachi S-4800 scanning electron microscope. The film thermal stability was tested with a Rubotherm Thermogravimetric Analyzer. Samples (about 80 mg) were heated from 50 to 600°C at a 10°C/min scanning rate, under nitrogen atmosphere.

3. Results and discussion

3.1 Apparent morphology of films

Fig. 1 The optimal composite hemicelluloses film

With a small amount of PVA and sorbitol, the hemicelluloses can form different films. Film thickness prepared by different amount of PVA showed no significant difference with an average thickness between 0.09~0.12mm. In Fig.1, the color of the composite hemicelluloses film is dark yellow due to a little lignin left. Since it was too fragile when the ratio of PVA to hemicelluloses was under 20%, PVA ratio increased up to 30% to improve the mechanical properties, Taking the cost and practicability into account, the optimal ratio of PVA to hemicelluloses was determined to be 30%.

3.2 Mechanical properties of the optimal films

The films are mainly characterized by their mechanical properties, which includes: tensile strength (TS), elongation at break (E) and elastic modulus (EM). Mechanical properties are an indication of the integrity of films on subjecting to stress conditions. TS is a measurement of film strength and is calculated by dividing the maximum force needed to break the films by the cross-sectional area of the films[8]. Whereas, E-value is an indication of flexibility of films. EM (also known as Young's modulus) is a measurement of stiffness of the films[9].

As the stress-strain curve shown in Fig. 2, the film had a high EM values, indicating that the film had a certain degree of rigidity. With the PVA and sorbitol addition, the composite hemicelluloses film showed a TS of 4.6 MPa, E-value of 6.4%. Mechanical Properties were affected not only by process conditions, but also by different types and compositions of hemicelluloses. In this study, the hemicelluloses used is extracted with hot water method, which was born to have a lower polymerization degree and a shorter molecular chain than hemicellulose extracted by other methods, such as the alkali pretreatment method, then resulting in a lower adhesive strength of intermolecular. So at the macro level, the TS value of films was relatively low.

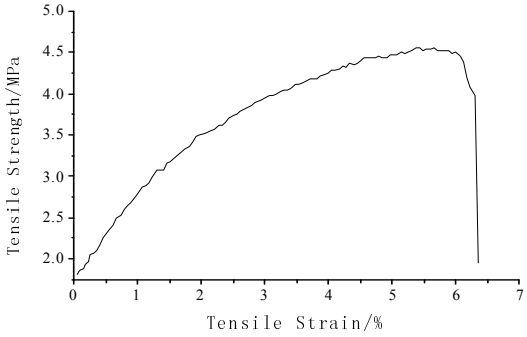

Fig. 2 The stress-strain curve of films

3.3 Microstructure Characteristics

The composite hemicelluloses films were smooth, semitransparent. Fig. 3 shows micrographs of the surface and cross-section areas of films. The outer surface image showed that the films had a uniform and continuous surface, and the cross-section areas showed dense, homogeneous structures without the phase separation. All of this indicated that the hemicelluloses, PVA and sorbitol had a good biological compatibility.

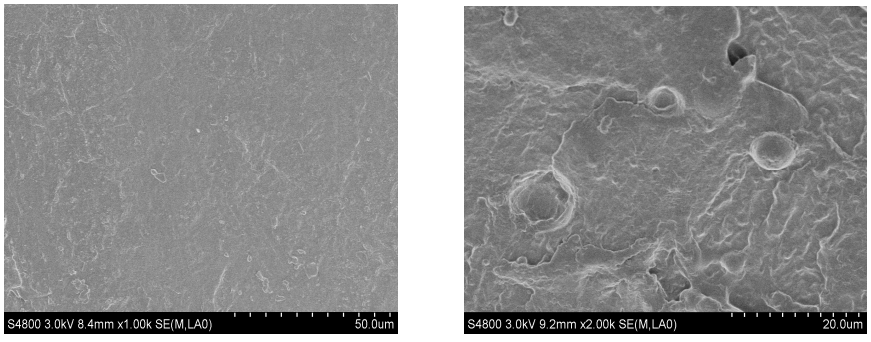

Fig. 3 The surface (left) and cross-section (right) areas SEM images of films

3.4 Thermal Characteristics

The thermogravimetric curves of the composite hemicelluloses films are showed in Fig. 4. The weight loss in the temperature range of 50–190°C was assigned to the evaporation of water from the samples. The decomposition temperature of films began at 190°C, suggesting intercomponent compatibility resulted in a strongly interacting system. The biggest Weightlessness rate range is 210°C ~310°C. These decomposition stages could be ascribed to backbone scission and following fragmentation of hemicelluloses and the additive. This high temperature illustrated that the composite hemicelluloses films is thermally stable.

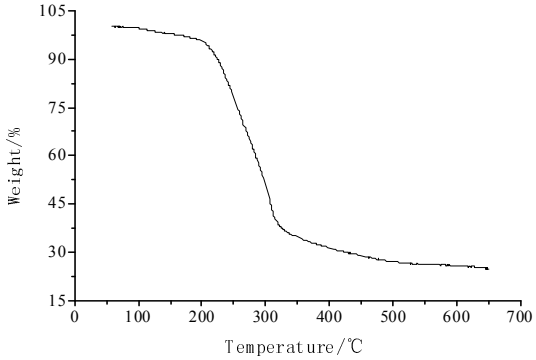

Fig.4 Thermograms of the films

4. Conclusion

Agricultural waste such as corncob can be obtained in large quantities every year. However, most of the corncob is burnt in the fields which can cause environmental problems. Corncob hemicelluloses were extracted by the hot water treatment method and showed that the corncob hemicelluloses has a potential for production of films. Adding 30% PVA and 10% sorbitol to the hemicelluloses, the components can form a continuous films. The composite hemicelluloses films were smooth, semitransparent. In addition, it showed a TS of 4.6 MPa, E-value of 6.4%, and a nice thermally stability.

Keywords: Atmospheric particulates; Aerosols hygroscopic; Analysis

Abstract. With the rapid development of economy and the acceleration of the process of city, the problem of the atmospheric particulates is getting more and more serious which has severe impact on human health. Consequently the atmospheric particulates weather management has become a very realistic and an urgent problem to solve. The atmospheric particles mainly consists of water soluble aerosol and non water soluble aerosol. For the water-soluble aerosol should be removed by aerosol hygroscopicity, and for non water soluble aerosol by method of atmospheric water vapor liquefied or artificial humidification, making the small water droplets in the air further increase. So the water vapor can absorb non water soluble aerosol, through the settlement removal.So the utilization of these principles can achieve the purpose of absorbing the atmospheric particulates in the air.

Introduction

Since the 1950s, although the fog-haze phenomenon has often occurred around the world, but in China it happened rarely. However, in recent years in our country the degree and frequency of occurrence in the winter season has increased significantly. Especially in 2013, a wide range of national severe haze caused by concentration of the atmospheric particulates in the air persistently elevated, not only the transportation, but also have a serious impact on public health. Meanwhile, fog-haze also have adverse effects on agriculture. Research shows that too much atmospheric particulates make the decrease of crop yields up to 25%. When he talked about the problem of air pollution control, Premier Li Keqiang emphasized that though the fog-haze problem solving requires a long-term process, but we must do something[1]!

The atmospheric particulates concentration to rise is an anthropogenic pollution phenomenon caused by human economic activity. The green GDP accounting results issued by Ministry of Environmental Protection show that from 2004 to 2009, the cost of environmental pollution has increased from 511.8 billion yuan to 970.1 billion yuan, indicating that China's economic development environment pollution costs continue to rise[2]. At present, in China the cause of atmospheric particulates formation is mainly by industrial sources, most of which are coal-fired industrial and vehicle emissions, in which coal-fired for power generation is the most, taking up about half of the total coal consumption. The eighteen meeting of the Communist Party proposed the development goals of "two hundred years". To achieve these two objectives, we still need to consume large amounts of energy, causing more serious environmental pollution. Therefore, we should vigorously develop new energy technology, pollutant removal technology.

Definition and composition of the atmospheric particulates

The atmospheric particulates are the general term for various solid and liquid particles in the atmosphere. The grains constitutes a large relatively stable suspension system dispersed evenly in the air, namely aerosol system. Particle size is generally in the range of 0.01~100 microns.The main cause of atmospheric particulates problem in our country is serious aerosol pollution. At present, the subjective reasons of formation of atmospheric particulates are pollutant emissions. Therefore we should intensify the control of pollutant emissions and carry out the governance of air pollution.

The atmospheric particulates has very complex composition, including hundreds of particulates, such as mineral grains, salt, sulfate, nitrate, organic aerosol particles. Mineral aerosols (including

soot, dust and urban fugitive dust, etc.) are the largest content of atmospheric particulates component in China, accounting for about 35%. Sulfates and organic carbon aerosols are two other large components, respectively, accounting for about 15%. These three categories of aerosols contribute approximately 70% of the atmospheric particulates mass concentration, while nitrate about 7%, ammonium about 5%, black carbon aerosols only about 3.5%[3]. Therefore, the main component of atmospheric particulates is aerosol particle. When aerosols remain in the atmosphere, it is formed by the nucleation mode particles aerosols through coagulation, aggregation, adhesion and other processes. It absorbs a variety of gaseous and solid pollutants in the air. From the perspective of harm to human health, the particles whose size are larger than 2 μm mainly deposited in the human nose and throat, while those less than 2 μm are mostly deposited in the bronchi and alveoli, causing great harm to the human body, resulting in our more concern[4]. Therefore, the atmospheric particles mainly consists of water soluble aerosol and non water soluble aerosol. For the water-soluble aerosol should be removed by aerosol hygroscopicity, and for non water soluble aerosol by method of atmospheric water vapor liquefied or artificial humidification, making the small water droplets in the air further increase. So the water vapor can absorb non water soluble aerosol, through the settlement removal.

Liquefied conditions of water vapour

Liquefying water vapour need to have sufficiently low temperature heat source. At first the low temperature heat source absorbed the sensible heat, cooled the water droplets to its condensation temperature, then the water vapour become saturated vapor. At this temperature, it continued to absorb its latent heat of condensation, then the saturated vapor convert into fog droplets. This is the general liquefaction of water vapour. Obviously, a sufficiently low temperature heat source is important for liquefying the water vapour[5].

If the temperature of the water vapor is higher than its critical temperature, regardless of how much pressure is applied, it will not be liquefied. So the necessary condition of the liquefaction is the temperature below its critical temperature, while the sufficient condition is that the pressure at the temperature is greater than the saturation vapor pressure. This is because when the water vapor temperature decreases, it will reduce the kinetic energy of molecules, weaken the molecular repulsion; when the pressure increases, it will shorten the distance between molecules, lead the mutual attraction between the molecules increasing. When the mutual attraction is greater than repulsion, in other words, when the attraction plays a leading role, the water vapour will liquefy. Therefore, if the water vapour is at or below its critical temperature, the appropriate increase in pressure will convert it into the liquid from the gas. If the temperature is higher than the critical temperature, the kinetic energy of molecules is large enough to overcome the attraction between molecules. Even if great pressure is applied to shorten the distance between molecules, the repulsive force is greater than intermolecular attraction, so the water vapour cannot be liquefied[6]. Therefore, the liquefied condition of water vapour is at or below its critical temperature.

In conclusion, cooling and pressing are both important and principal physical process to liquefy the water vapour. And, of course, in addition to the temperature and air pressure, air circulation is also influential to liquefaction. The appearence of dew in the summer morning, for instance, is related to whether there was a wind during the night, and dew cannot be formed if it was rather windy last night. It is thus clear that, the more circulation of the air, the less possible that liquefaction will happen.

The feasibility of water-soluble aerosol hygroscopic growth

Study of aerosol hygroscopicity is at the basic position in atmospheric particulate control. Hygroscopicity is the main properties of aerosols, which is the water absorbing capacity of aerosol when the relative humidity of the ambient environment increases. Relative humidity changes are the main factors affecting aerosols hygroscopicity, when the relative humidity reaches the deliquescence point, aerosols absorb a large amount of water leaving the particle size become large. At high relative humidity, hygroscopic aerosols such as small crystals deliquesce into larger droplets as a result of moisture absorption, and then they can be quickly removed from the atmosphere through some methods (such as subsidence)[7].

Fig. 1 was the Cora curve of water-soluble particles hygroscopic growth. Seen from the figure, when ambient vapor pressure is less than the critical value, even though dry hygroscopic particles can grow, they cannot exceed the critical radius scale but only form water vapour. In other words, if the haze drop wants to become droplet through hygroscopic growth, there must be a sufficient degree of supersaturation over the hump, which is not easy to achieve in nature. Therefore, we must conduct hygroscopic growth through artificial means in order to over the supersaturation hump to form droplets.

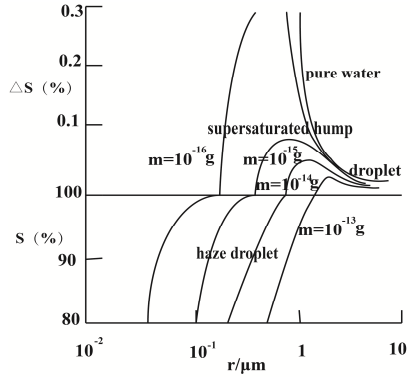

Fig. 1 The Cora curve of water-soluble particles hygroscopic growth

According to article written by GAO Jian et al.[8] published in Inter-comparison of WPS-TEOM-MOUDI and Investigation on Particle Density, we got the particles density within the scope of different size in Shanghai and Beijing.Shanghai inTable 1,for example:

Table 1. The density of particles within different size in Shanghai

The lower limit of particle size/μm	The upper limit of particle size/μm	Density/g.cm^{-3}
0	0.32	0.81
0.32	0.56	6.15
0.56	1.00	1.54
1.00	1.80	1.22
1.80	3.20	0.92
3.20	5.60	2.18
5.60	10.0	1.37

Then according to the size limit, we can calculate the particle average diameter size.According to $V = \frac{1}{6}\pi D^3$ and $m = \rho V$, it can be obtained in Table 2:

Table 2. The mass of particles within different size in Shanghai

The lower limit of particle size/μm	The upper limit of particle size/μm	Density/g.cm^{-3}	Mass/g
0	0.32	0.81	1.74×10^{-15}
0.32	0.56	6.15	2.74×10^{-13}
0.56	1.00	1.54	3.82×10^{-13}
1.00	1.80	1.22	1.75×10^{-12}
1.80	3.20	0.92	7.52×10^{-12}
3.20	5.60	2.18	9.72×10^{-11}
5.60	10.0	1.37	3.40×10^{-10}

Known from the Cora curve, with the increase of particle mass, the critical supersaturated hnmidity goes smaller, making it easier for hygroscopic growth. Mass of the haze particles from the table ranges from 1.74×10^{-15}g to 3.40×10^{-10}g, showing that the need of the critical saturationto is low. Analysis of the measured data shows that the extreme minimum relative humidity for fog existence is 91%[9]. However, when there is more water vapor in the air, some strong absorbent dry aerosol particles will absorb water, grow up. From the observation in North China, we can find that the aerosol particle size after absorb moisture will increase 20% ~60%[10]. Thus, humidification can increase particle size, decrease relative humidity, make it easier to convert into the droplet from the water vapour.

Conclusions

The structure of the energy consumption of China is mainly dominated by coal, fossil energy accounted for 92.7% of overall energy structure. Facing the situation of resource constraint tightens and serious environmental pollution, the transformation of the mode of development, optimizing the energy structure and adjustment of industrial structure is the only way to reduce the frequence of fog haze weather[11]. The eighteen Party's report also pointed out that, "the construction of ecological civilization, is the relationship between people's well-being, concerns national future long-term strategy. Placing the ecological civilization construction in a prominent position, the integration of economic construction, political construction, cultural construction in all aspects and whole process, and strive to build a beautiful China, realize the sustainable development of the Chinese nation."

The atmospheric particles not only have an adverse effect on human health, but also causes atmospheric low visibility, prone to traffic accidents, threat the safety of people. For the removal of atmospheric particulates by cooling, pressure or artificial humidification can make water vapor liquefy, and then increase the particle size, adsorption of non hygroscopic aerosol particles more. But for hygroscopic aerosol particles through the Rescorla curves, when reaching the critical relative saturation wetness, aerosols hygroscopic growth. Finally through the settlement, it achieve the purpose of absorbing the atmospheric particulates in the air.

Keywords: Ni element, weathering steel, weight loss, rust, EIS

Abstract: Corrosion behavior of a low alloy steel A with 3% nickel content was studied by a wet/dry cyclic test. A commercial weathering steel Q450NR1 was used for comparison. The classical weight loss method was used to evaluate the weatherability of weathering steel, while the iron rust layers formed on weathering steel were analyzed by using SEM, XRD and electrochemical measurements. The results indicated that the corrosion resistance of steels A was better than that of commercial weathering steel Q450NR1 in the wet/dry cyclic test. The addition of Ni promoted the formation of α-FeOOH so as to improve the resistance of the rust. The EIS results indicated that the charge transfer resistance of steel A was bigger than that of steel Q450NR1.

Introduction

Metal corrosion is a serious problem, which exists in various fields of national economy and national defense construction[1]. So weathering steel has been widely used due to its excellent atmospheric corrosion resistance performance in atmospheres which results from that the alloying elements such as Cu, Cr, Ni, Si, P, etc. in the steel can promote to form a dense and adhesion stability protective film[2]. Nowadays, Ni plays an important role in the corrosion process of structural steel. The steel with Ni can make the selfcorrosion potential move to the positive direction, which increases the stability. The atmospheric exposure research results showed that the corrosion resistance in the sea side environment of the weathering steel with about 4 wt% Ni can be significantly improved[3]. Japanese scholars[4] did the reaches on the corrosion resistance of weathering steel with 3% wt% Ni in the coastal environment and they found that the grain was refined and the density was increased because of the enrichment of Ni in the rust layer. It was difficult for the chloride ion to get through the rust layer to the steel substrate resulting in the reduction of the corrosion rate of the weathering steel. I. Diaz[5] found that weathering steel containing Ni exposured in Marine atmospheric environment of medium chloride ion erosion after a year showed better corrosion resistance, and the higher of the Ni content the better corrosion resistance it had, It was because that the existing of Ni promoted the formation of the nano phase and superparamagnetism α-FeOOH in the inner rust layer, and the particles size of α-FeOOH was less than 15 nm, which can increase the density of the rust layer leading to the improvement of marine atmospheric corrosion resistance.

In this paper, the characteristics of the steel with Ni and conventional weathering steel were investigated in detail after wet/dry corrosion test. And the effect of Ni in improving the corrosion resistance of weathering steel was explored.

Experimental

Composition of tested steels. The steel A with 3 wt% Ni and commercial weathering steel Q450NR1 were used as tested steels and their chemical compositions are given in Table 1.

Table 1 Chemical composition of test materials (wt%)

steel	C	S	P	Mn	Si	Cr	Ni	Cu	Fe
A	0.075	0.0068	0.012	0.80	0.39	0.502	0.193	0.243	rest
Q450NR1	0.081	0.0058	0.0061	0.89	0.40	0.505	2.939	0.272	rest

Periodic immersion wet\dry cyclic corrosion test. The atmospheric corrosion resistance of weathering steels was evaluated through a periodic immersion wet/dry cyclic corrosion test, which was an accelerated corrosion test method under artificially simulated atmospheric environment. There were three parallel samples and the dimension of the sample was 60mm×40mm×5mm. Each cycle of wet/dry cyclic corrosion test lasted for 1 hour and included two stages: (1) immersing the specimens into 2 wt% NaCl aqueous solution for 12±1.5 min (2) drying the specimens immediately after immersion by heating lamps (the surface biggest temperature of the specimens was 70±10℃), subsequently holding the specimens in the testing chamber with a constant humidity of RH 70±5% at 45±2 ℃ totally for 48 min. The total corrosion test lasted for 96 cycles, i.e. 96 h. In this test, 2 wt% NaCl aqueous solutions were used to simulate a marine atmosphere, which is one of the typical atmosphere environments encountered during the application of weathering steels.

A chemical dissolution method was adopted to remove the corrosion layer, i.e. immersing the as-corroded specimen in a vigorously stirred specific diluted hydrochloricacid solution (500 ml HCl+500 ml distilledwater+3.5 g hexamethylenetetramine) for at least 10 min at room temperature[6,7].

Rust analysis. The powdered rust was scraped off from the rusted samples and the powdered rust samples were characterized by means of X-ray diffraction (XRD) to determine its composition. The XRD measurements were carried out using a Rigaku-D/max2000 diffractometer with a Cu Kα target under 50 kV, 250 mA and with a scanning range of 5-40° at a scanning speed of 2° min^{-1}. The rusted samples for cross-sectional analysis were observed using scanning electron microscopy (SEM). SEM observation was performed with a HITACHI_S-4300.

Electrochemical measurements. Polarization measurements were performed with a Model 273A-M398 Potentiostat/Galvanostat at a 0.332mV/s scan rate in 2 wt% NaCl solution while keeping the solution in 30±2 ℃ by using a water bath pot. It used a saturated calomel electrode (SCE) as reference and a Pt counter electrode. The scan range was -250 mV to 250 mV. The steel samples were manually sectioned into coupons of dimensions 10 mm×10 mm×3 mm, which served as the working electrode.

The electrochemical impedance spectroscopy (EIS) measurements were carried out over the frequency rage 100 kHz to 10 mHz with a 5 mV amplitude signal at open circuit potential. Before all the electrochemical experiments were performed, the specimens were kept in the solution for half an hour in order to attain a stable open circuit potential. Electrochemical impedance spectroscopy (EIS) measurements of the bare and rusted steel were carried out in 0.5 wt% NaCl solution.

Results and discussion

Corrosion rate of weathering steel. The corrosion rate of the steels in the artificially simulated marine corrosive atmosphere was determined by weighing the unaffected substrate part of each specimen before and after the tests. The weight loss rate could be determined using the following equation:

$$W = \frac{G_0 - G_1}{S \times t} \quad (1)$$

Where W is the weight loss rate (mg/(cm^2·h)), G_0 is the initial weight of the specimen before corrosion test (mg), G_1 is the weight of the as-corroded specimen after its surface corrosion product was removed (mg), S is the initially total surface area of the specimen(cm^2), t is the test time (h)[8].

Fig.1 presents the corrosion rate of the tested steels. It can be seen clearly that the weight loss of the steel A with 3% wt% Ni is much lower than that of Q450NR1, indicating that the effectiveness of Ni for using in salt-rich environment.

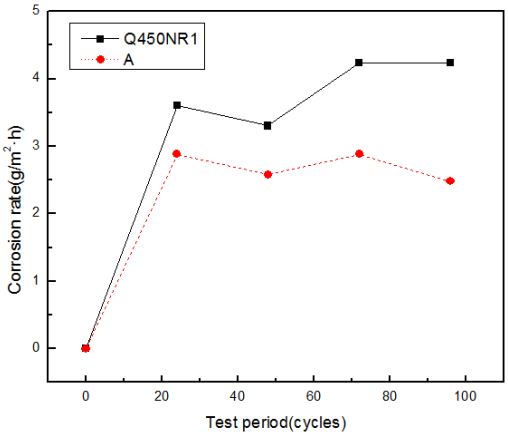

Figure 1.The corrosion rate of the tested steelswet/dry cycles

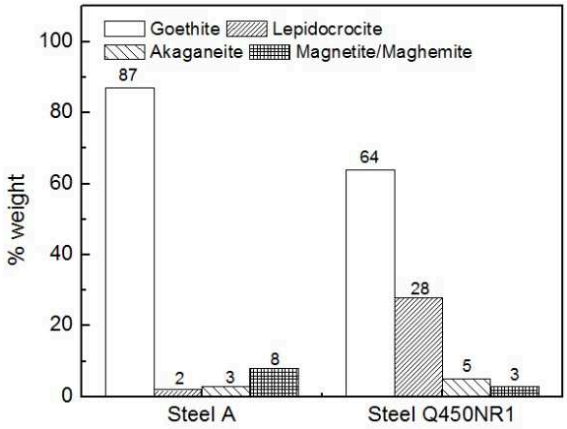

Figure 2. XRD semiquantitative analysis of corrosionproducts formed on steel A and Q450NR1

Composition and structure of rust layer. It can be seen from the XRD that patterns of the rust layers formed on the two steels after periodic immersion wet/dry cyclic corrosion for 72 h, crystalline corrosion products were formed. The rust layers consist of maghemite (Fe_2O_3), magnetite(Fe_3O_4), lepidocrocite(γ-FeOOH), goethite(α-FeOOH) and akaganeite(β-FeOOH). Fig.2 shows the constituents of steel A and Q450NR1 from a semiquantitative analysis. From this results it can be concluded that the additions of Ni could greatly promote the transformation of lepidocrocite(γ-FeOOH) to goethite(α-FeOOH). It has been reported that goethite (α-FeOOH) is non active in the corrosion process, and the γ-FeOOH phase acts as the oxidation agent that accelerates corrosion in a chloride-free environment[9,10]. Furthermore, the addition of Ni decrease the content β-FeOOH which plays the primary role in accelerating the corrosion rate[11].

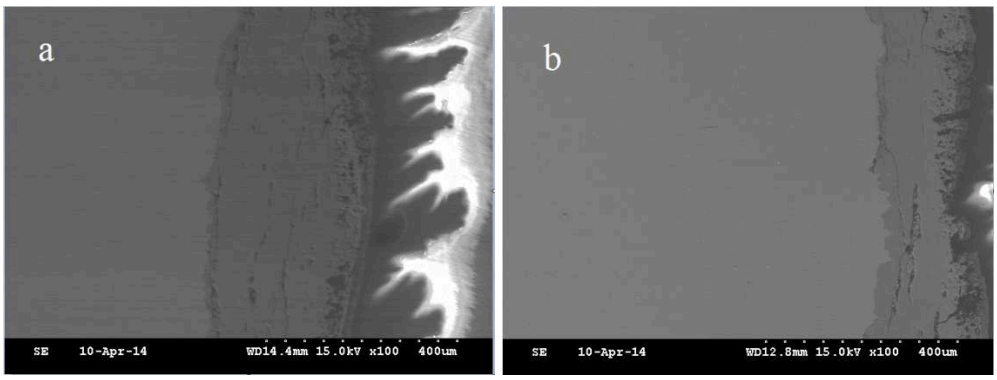

Figure 3. The cross-sectional morphologies of rust layers: (a) Steel Q450NR1 (b) Steel A

The cross-sections of the steels after 72 cycles of accelerated tests were observed by SEM, as shown in Fig.3 (a) and (b). It shows that the rust layers in these test steels all contain voids and /or micro-cracks. Both of them are composed of two parts: the loose outer layer and the dense inner layer. However, the inner rust layer of steel A is denser while the voids and micro-cracks are fewer. Meanwhile, the thickness of the rust layer of steel A is about 200-300μm thinner than that of steel Q450NR1 (400-500μm).

Electrochemical measurements. Fig.4 illustrates the polarization curves of the bare steel A and Q450NR1 in NaCl solution. It can be seen clearly that the selfcorrosion potential of the steel A is higher than steel Q450NR1. It indicates that the corrosion of steel A is harder to occur.

The Nyquist impedance plots of the two bare steels are shown in Fig.5, which show a well defined semicircle. The semicircle diameter of steel A is larger than that of Q450NR1 which means that the corrosion resistance of bare steel A is higher than that of bare Q450NR1.

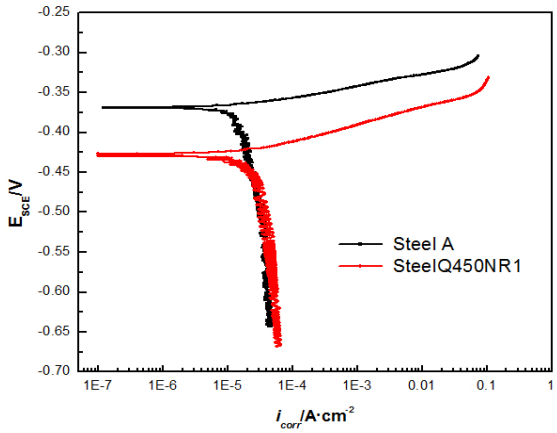

Figure 4. The polarisation of the bare steel of steelA and steel Q450NR1

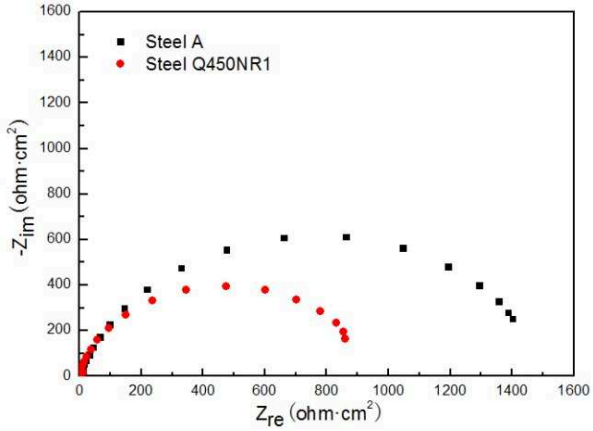

Figure 5. EIS for pre-corroded samples in a 0.5 mass% NaCl aqueous solution

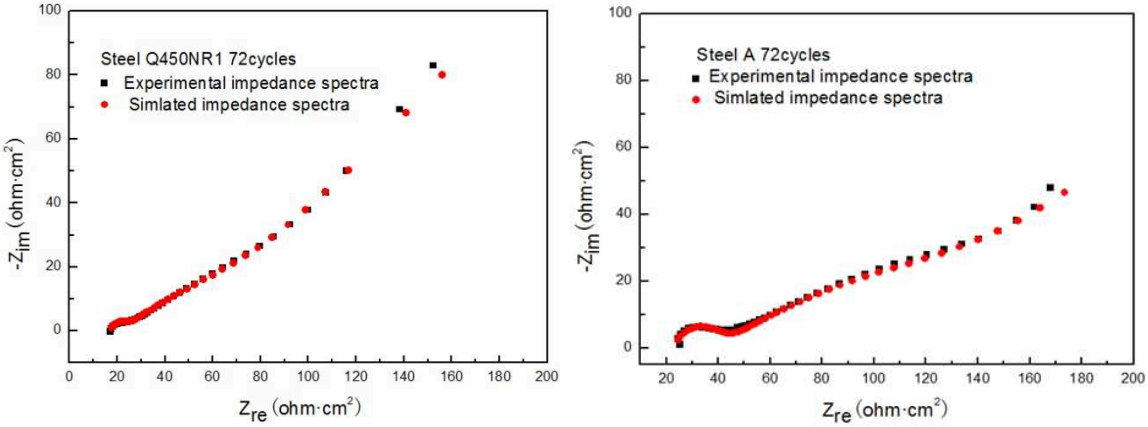

Figure 6. EIS of steel Q450NR1 and A that were subjected to a wet/dry cyclic test for 72cycles

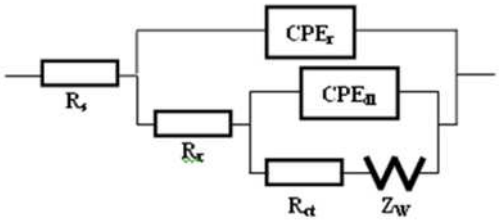

Figure 7. Equivalent circuit for specimens immersed in a 0.5 mass% NaCl solution

Fig.6 shows the Nyquist diagrams of steel A and Q450NR1 that were subjected to a wet/dry cyclic test for 72 cycles. The diagrams of the two steels are consisted of a depressed semicircle at the high frequency region and a long tail at the low frequency region. As can be seen in Fig.6, the impedance data can be well fit, marked by the rounded points, using the equivalent electrical circuit (as shown in Fig.7). There is no obvious interface between the outer rust layer and the inner rust layer. Besides, the inner rust layer can transform into the outer layer as the corrosion proceeds. So, for EIS fitting, it is considered the two layers as a whole. In this case, R_r and CPE_r represente the resistance and capacitance represente the rust layer, respectively. R_{ct} modeled the charge transfer resistance, CPE_{dl} describe the double layer capacity and W is used to model semi-infinite linear diffusion. The R_{ct} value of steel Q459NR1 is 125.2 Ω, while that of steel A is 186.4 Ω. The R_{ct} value of steel A increased to a certain degree, which implied that the charge transfer between the rust layer and the solution became more difficult. This can attribute to the increasement of the chemical activity stability α-FeOOH and the decreasement of the opposite effect γ-FeOOH, according to the XRD analysis above.

Conclusion

The weatherability of two weathering steels in wet/dry environments was discussed and the effect of Ni was clarified. The following conclusions can be drawn. The Ni can improve the corrosion resistance of the weathering steel obviously. It can improve the selfcorrosion potential of the bare steel. The addition of Ni can greatly promote the formation of chemical activity stability goethite (α-FeOOH), which increases the transfer resistance of charge and promotes the formation of a denser and adhesion rust layer, although there are the same crystalline corrosion products in the rust layer of different test steels.

Keywords: Microstructure; Corrugated Waist Rail;Rolling Process Simulation; DEFORM-3D

Abstract. Applying the research result of the whole corrugated web H-beam to rail structure, a new kind of rail structure, the corrugated web rail was generated. The special structure rail was successfully rolled in the Research Mill Institute of Yanshan University. Based on the finite element analysis software DEFORM-3D, the rolling process of corrugated waist rail is simulated. The miscrostructure evolution of rolling corrugated waist rail is analysed. The relationship between miscrostructure evolution and deformation are also analysed.

Introduction

The research result on the whole corrugated web H-beam is applied to rail structure[1][2], thus, a new kind of rail structure, which is corrugated web rail, is developed. The corrugated web rail is one important way to improve the economic properties of classical rail, and it has great significance on the economy and science. The research on the corrugated web rail is initiative in the world. The corrugated web rail has been successfully rolled in the Rolling Mill Research Institute of Yanshan University[3][4]. This is shown as Fig.1. Because forming corrugated web rail is complex, the corrugated web rail is only formed by the last pass. The corrugated waist rail has the characteristic of higher strengthen and stiffness. The rolled corrugated waist has the characteristic of higher productivity and higher precision.

FEM Model

The rolling simulation model is set up according to 18kg/m traditional rail. In rolling experiment, because the height of the vertical roller is small, the part of rail base of rolling piece was cut out to meet with the experiment condition. Before the last pass, the flange and web have been rolled down in the roughing stand and flanges edged respectively. The profile curves of upper and lower horizontal rollers for forming corrugated rail web are shown in the Fig. 2. The lower roller should be rotated with the degree of 180 / z, where z is the teeth number of the tooth-shaped roller, then the teeth of the upper roller and lower roller are matched correctly. The diameter of pitch circles is 269mm, the diameter of the addendum circle is 278mm and the diameter of the root circles is 260mm. The profile curve of each tooth is made up by three segments tangent arcs, two arcs diameters are 14.02mm and one is 22.68mm. The teeth number of these tooth-shaped rollers is 18. The profile of each tooth is also shown in Fig. 2. The phase angle degree of each tooth is 20°. The rolling model is shown in Fig. 3.

Microstucture Simulation Analysis in the Rolling Process

P1, P2 two points are selected from the corrugated waist rail, P1 is in the corrugated rail waist, P2 in corrugated rail waist on the junction of two wave. Applied Microstructure module of

DEFORM-3D, two points of microstructure are simulated. Variety of microscopic characteristics are shown in Fig.4. Grain size change in the rolling process is shown in Fig.5.

As shown in two figure of Fig.5, the first picture is grain, the second is grain and boundary, the third is grain boundary, the fourth is dislocation density.

As can be seen from Fig.5, dislocation density of P1 is bigger than that of P2, more grain boundary and grain size is smaller. Grain size difference of P2 is not bigger. The deformation of rail base is the least. The deformation of rail waist is bigger. But this is less than that of rail head. Therefore, the microstucture property of rail head is the best after the rolling process.

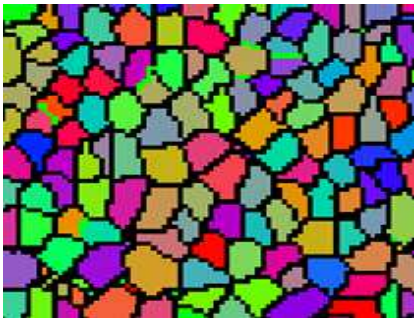
（b）P2

Fig.5 Changes in the process of rolling grain



P1

P2

Fig.6 Grain structure and grain size of P1, P2 point

As can be seen fromFig. 6 , the grain size of P1 is 23.1 μ m, the grain size of P2 is 24.6 μ m. The grain size of rail head is the smallest, that of rail waist is the second and that of rail head is the biggest. The grain size of rail waist , rail head is smaller than that of rail waist of two wave link parts.

In the actual production of the corrugated waist rail , at the last pass of rolling traditional rail, a pass of rolling corrugated waist rail is increased. The deformation of rolling corrugated waist rail is bigger than that of rolling traditional rail. This lead to grainof corrugated waist rail is smaller than that of traditional rail. Whereas, because of smaller deformation in rail head and rail base, there are not bigger difference in the grain size of rail head and rail base between the two kind of rail.

Roller profile with corrugated waist rail is complicated in shape. Because of rolling rail waist complex, the deformation amount and deformation force in the elongation direction are different. The microstructures and mechanical properties of the corrugated waist rail after rolling is uneven.

The recrystallization of metals, usually nucleation at maximum distortionin caused by the plastic deformation, such as the grain boundaries, deformation band, area with large inclusion etc. In the deformation zone, when the strain reaches the critical strain, dynamic recrystallization will occur.

After recrystallization, due to internal stress generated by plastic deformationcan be eliminated completely and finally metal tends to a stable state. Between the frame, the metal will not be deformed. When the strain is larger than the critical strain but less than the peak strain, after a period of time, static recrystallization will occur. When the strain is larger than the peak strain but less than the steady-state strain,static recovery and metadynamic recrystallization accompanied by static recrystallization will occur,.when the strain is bigger than steady state strain, metadynamic recrystallization and a small portion of static recovery will occur.

Conclusion

In the production of corrugated waist rail process, in order to improve the mechanical properties, the reduction must be increased and other factors should be taken into consideration. The grain size emerging larger temperature region and rolling velocity region of the rail head should be avoid. To make new rolling rules, the relationship between the matching speed and rolling schedule should be taken into consideration and the factors of rolling temperature, finishing temperature should be also considered.

Abstract. The corrugated waist rail has been successfully rolled in the Mill Research Institute of Yanshan University.Based on commercial FE software of DEFORM-3D, the recrystallization in the rolling process of corrugated waist rail was simulated, the factors affect the recrystallization are analyzed. The different reduces and rolling speed that affect the recrystallization are also analyzed.

Introduction

With the continuously increasing train speed and flow, It is of increasingly stringent requirements about heavy rail . In order to improve the performance and service life of the rail, a new kind of rail structure, corrugated web rail, is developed. The corrugated waist rail has been successfully rolled in the Mill Research Institute of Yanshan University[1], the rolled product is shown in Fig.1. It has been already tested that the mechanical properties of this kind of special structure rail are better than those of the ordinary structure rail. The new structure heavy rail is superior to the ordinary rail on rail waist lateral bending and longitudinal stability[2]. The dynamic properties are also improved[3][4].

Fig.1 The corrugated web rail

FEM model

The rolling simulation model is set up according to18kg/m traditional rail. In rolling experiment, because the height of the vertical roller is small, the part of rail base of rolling piece was cut out to meet with the experiment condition. Before the last pass, the flange and web have been rolled down in the roughing stand and flanges edged respectively. The profile curves of upper and lower horizontal rollers for forming corrugated rail web are shown in the Fig. 1. The lower roller should be rotated with the degree of 180 / z, where z is the teeth number of the tooth-shaped roller, then the teeth of the upper roller and lower roller are matched correctly. The diameter of pitch circles is 269mm, the diameter of the addendum circle is 278mm and the diameter of the root circles is 260mm. The profile curve of each tooth is made up by three segments tangent

arcs, two arcs diameters are 14.02mm and one is 22.68mm. The teeth number of these tooth-shaped rollers is 18. The profile of each tooth is also shown in Fig. 2. The phase angle degree of each tooth is 20°. The rolling model is shown in Fig. 3.

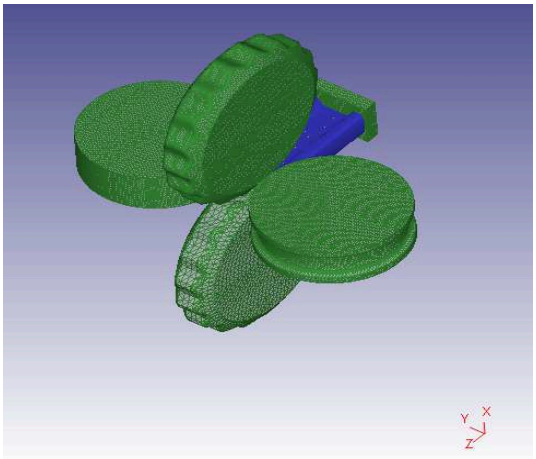

Fig.3 FEM model

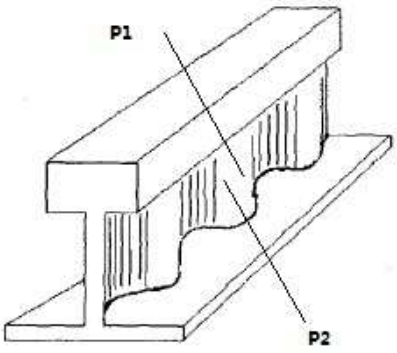

Fig.4 P1and P2 of corrugated rail waist rail

Simulation result and analysis

Deformation degree, deformation speed, temperature and structure evolution are coupled together by DEFORM-3D software. The simulation results, such as average grainsize, volume fraction of dynamic recrystallization and static recrystallization volume fraction ,etc. are analyzed.

In the corrugated waist rail stretch , one point P1 is picked from the wave peak , the other point P2 is picked from the two peak junction , as shown in Fig.4.

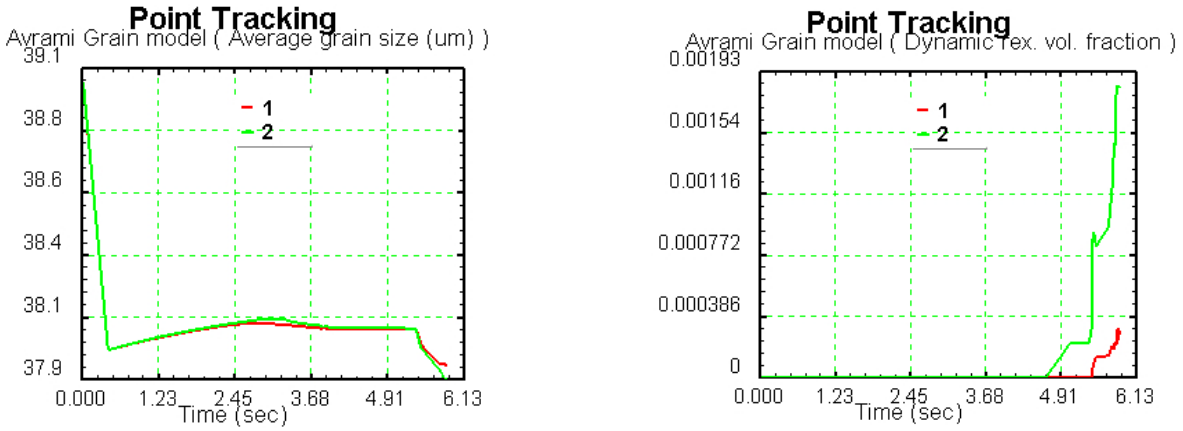
Different deformation degree influence

In order to more directly express the rolling piece grain change when increases the reduction, picking the same point at the corrugated waist rail rail waist as the observation point, using point tracing method in the post-processing, tracking the point in the relative reduction of 8% and relative reduction of 10%, grain size change and dynamic recrystallization volume fraction change.

Grain size curves and the dynamic recrystallization volume fraction curves with different relative reduction conditions of P1 is shown in Fig.5 and Fig.6 .

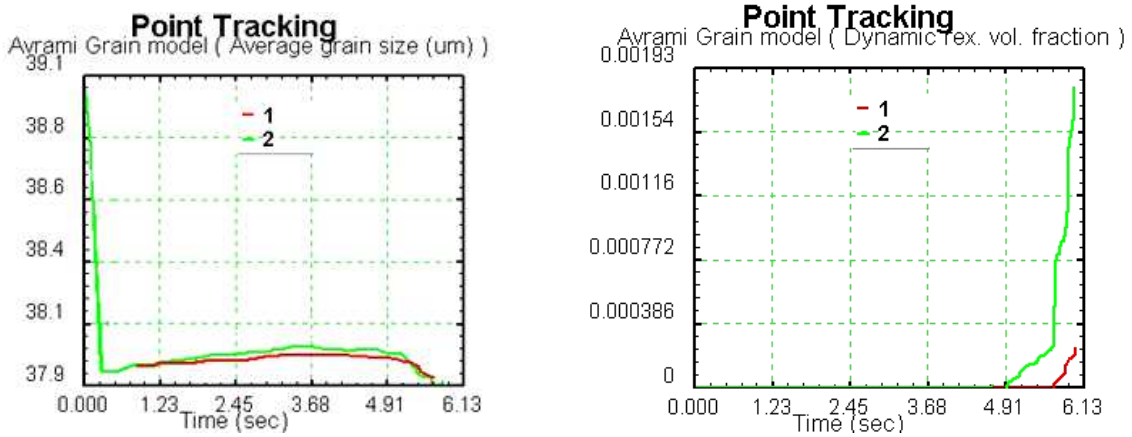
As can be seen from the Fig. 5 and Fig.6 can be seen in the relative reduction of 10%, P1 point and P2 point of grain grain changes little, about 1.2 um . The relative reduction is 8%, the grain and P2 grain size change P1 point is small, it is about 1.25um Thus it can be seen that the relative

pressure increases, the grain size decreases. With the increase of reduction ratio, the strength ,toughness and uniformity can be improved .



(a)average grain size (b) dynamic recrystallization volume fraction

Fig.5 Parameter changes in rolling（10%）



(a)average grain size (b) dynamic recrystallization volume fraction

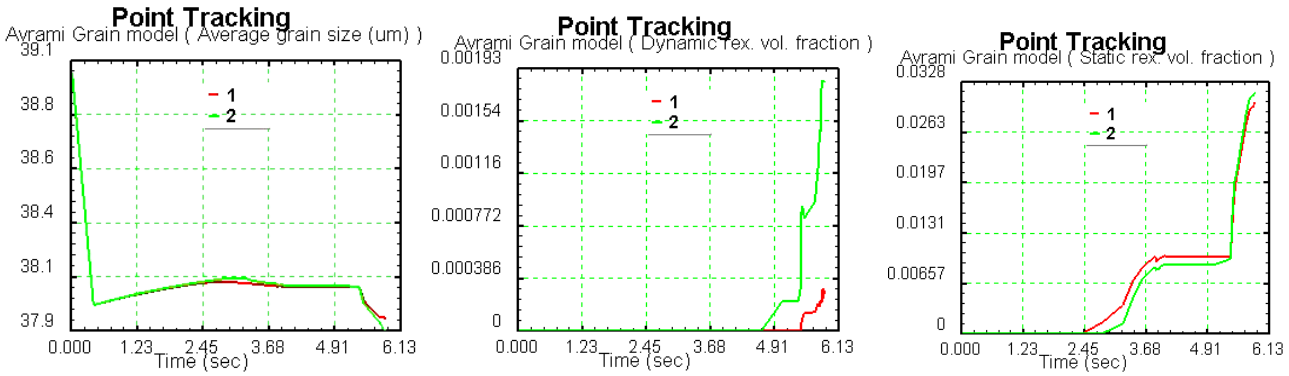
Fig.6 Parameter changes in rolling（8%）

Different rolling speed influence

At the condition of original reduction, the rolling speed increase to the double, as shown in Figure 20 the rolling process of corrugated waist rail is simulated. The rolling speed is set to 480mm/s, the same P1, tracking the parameters of this point is shown as Fig.7.

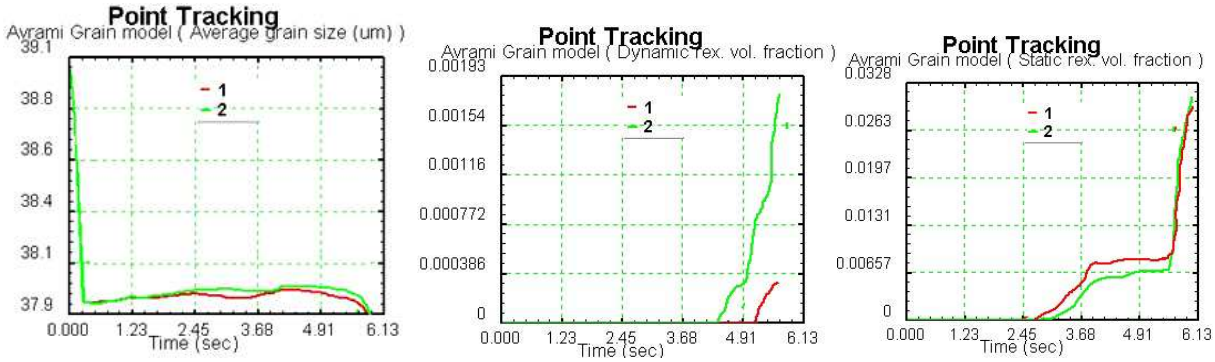
As shown in Fig.7, the average grain size of workpiece P1 point changes from 39 um to 37.94 um , the average grain size of P2 points changes from 39 um to 37.9 um .The grain size change is not obvious, the dynamic recrystallization time and is shorter than that of Fig.8 . At less than 2.45s, P1 point began to static recrystallization.

As can be seen from Fig.7 and Fig.8, it is the most obvious change of average grain size. when the rolling speed is 240mm/s, the average grain size is 67.3 μ m. When the rolling speed twicely increased, the average grain size is 37.9 μm. It is shown that the increasement of rolling velocity ,The refinement degree has a certain influence. After rolling velocity, shorten the time of dynamic recrystallization, but it increases the equivalent strain, deformation temperature is lower, so the grain size decreases. Rolling speed changes can also cause the change of plastic strain and temperature, which leads to the different microstructure evolution, grain size change. Thus, in metal rolling process, the rolling speed change can lead to change of the temperature of workpiece, the equivalent plastic strain and the dynamic recrystallization time .



(a)average grain size (b) dynamic recrystallization volume fraction (c)static recrystallization volume fraction

Fig.7 Several parameter changes in rolling(240 mm/s)



(a)average grain size (b) dynamic recrystallization volume fraction (c)static recrystallization volume fraction

Fig.8 Several parameter changes in rolling (480m/s)

Conclusion

Without changing the rolling speed, increasing the reduce can make the grain size smaller. Increasing the rolling speed, the grain can be refined.

Behavior of geosynthetic clay liners due to the migration of heavy metal

Fan Jingjing[1, a *]

[1.] Changsha Environmental Protection Vocational College, Jing Gui Rd, Changsha, Hunan, 410004, China

[a] fjj-07@163.com

Keywords: Behaivor, Geomembrance, GCL, Liner system, Migration

Abstract. To protect the underlying soil and groundwater from landfills, the landfills are commonly lined with layered liner systems. Geosynthetic clay liners (GCL) have been increasingly used in the landfill liner systems to substitude the traditional compacted clay liners (CCL) because of their low cost, easily construction behavior and low leakage rate. To study the behavior of the GM+GCL liner system used in China due to the migration of Pb^{2+}, we introduce in detail GM+GCL liner systems proposed by the Chinese specification. Then one dimensional finite layer model is used to investigate the anti-pollution behavior of the CM+GCL composite liner systems, with the focuses on the heavy metal Pb^{2+}. It could be concluded that the main migration way through the GM+GCL composite liner system is that the transport of Pb^{2+} through a GM+GCL composite liner system of a landfill cover takes place primarily through the holes in the GM. The findings provide useful reference for preventing, controlling and treating groundwater pollution in the GM+GCL liner system technically and scientifically.

Introduction

According to a recent report, there are 1.2 billion people lack access to clean drinking-water and there are about 2.6 billion have few or no sanitation services[1]. The groundwater is one of the most significant sources of drinking-water. More than 20% of the total drinking-water supply in China is provided by the groundwater in the past thirty years. And there are about 50% of the drinking-water supply is attributed to groundwater in the US. However, the municipal landfills press a great threat to the groundwater due to contamination. In the present, landfilling is main treatment method for municipal solid wastes in China. Consequently, the pollution of groundwater due to landfilling should be assessed analytically[2-3].

To protect the underlying soil and groundwater from landfills, the landfills are commonly lined with layered liner systems. Geosynthetic clay liners (GCL) have been increasingly used in the landfill liner systems to substitude the traditional compacted clay liners (CCL) because of their low cost, easily construction behavior and low leakage rate [4-5]. A number of countries have published technique standards of the GM+GCL composite liner system in accordance to their scientific investigation and practical experience. The Chinese specification (CJJ113-2007) [6-7] specifies a suggestion that recommends the use of GM+GCL composite liners, as shown in Fig 1. The thickness of the GM is 1.5mm. And the thickness of the GCL is 13.8mm. The permeability of the GCL is required to be lower than 5×10^{-11} m/s.

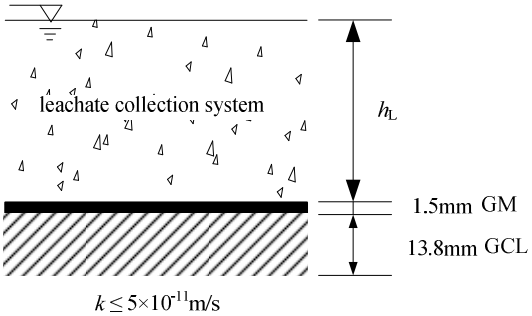

Fig 1 The GM+GCL liner system

In order to investigate the behavior of the GM+GCL composite liner system, an analytical model for the pollutant advection-dispersion-adsorption through the GM+GCL composite liner system is needed. Analytical models for pollutant advection-dispersion through layered liner system have usually been established numerically due to their complicated mathmatical equations. Rowe [5] conducted a comparative study among 3 kinds of composite liner system in the landfill, including GM+CCL, GM+GCL and the double-layered lined system. Xie [8] developed a one-dimensional mathmatical model for pollutant dispersion and advection through a GM+GCL composite liner system to make a comparative study between the behavior of the GCL and the CCL (compacted clay liner). Zhang et al. [9] established a mathmatical model for pollutant migration through a multi-layered landfill bottom liner system by the finite difference method.

Previous reports mainly studied the seepage performance of the GM+CCL composite liner systems according to various kings of structures. The behavior of GM+GCL liner system under the migration of Pb2+ is rarely studied. To study the behavior of GM+GCL liner system, we established a analytical model on the leakage behavior of the GM+GCL composite liner system.

Analytical model

Chinese standard - Technical code for liner system of municipal solid waste landfill- CJJ113-2007 [7] proposed a composite liner system. The high-density polyethylene geomembrance and the compact clay layer liner system is composed of a compact clay layer with a thickness of 0.75m covered by the high-density polyethylene geomembrance with a thickness of 1.5 mm. The coefficient of hydraulic conductivity of the CCL should be less than 1×10^{-9}m/s.

The assumed landfill model has a total length of 150 m in the direction parallel to the flow of the undergroundwater. The pollutant of heavy metal Pb^{2+} is included. The Pb^{2+} is a common kind of heavy metal contaminant in the leachate collection system. The concentration of Pb^{2+} can be assumed as 2 mg/L [8]. Baed on the drinking water standards of the US, the maximum contaminant level (MCL) for Pb^{2+} is suggested to be 0.01 mg/L. Then we could obtain the relative critical concentration of Pb^{2+} by subdivede the initial concentration to the MCL, which is 0.005. The pollutant characteristics are calculated based on Rowe [10-11]. The diffusion coefficient of GM is 7.2×10^{-15} m^2/s. The hydraulic conductivity of GCL is 5×10^{-11} m/s. The hydraulic head is 0.3m as specified in the standards.

Analysis results and discussion

The concentration versus time curves are shown in Fig 2. The location of concentration of Pb^{2+} is at the bottom of the GCL. This picture shows that the concentration of the Pb^{2+} at the bottom of the GCL grows with the growth of time. The concentration adds gradually in the time analysed.

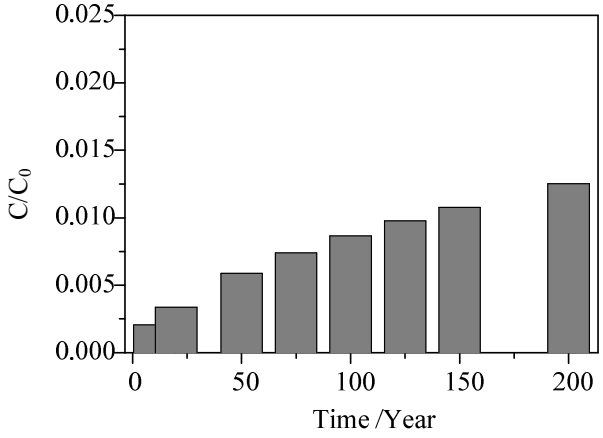

Fig 2 The concentration-time curves at the bottom of GCL

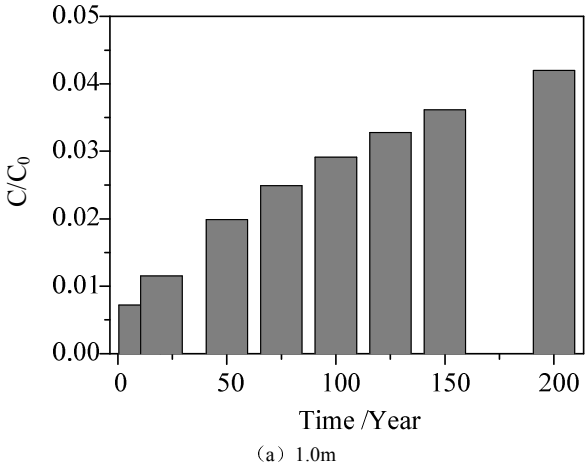
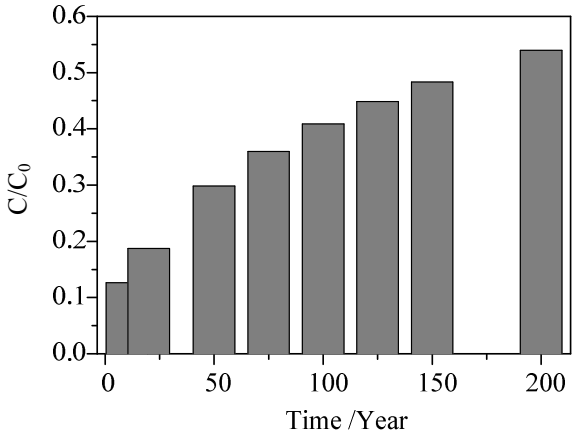
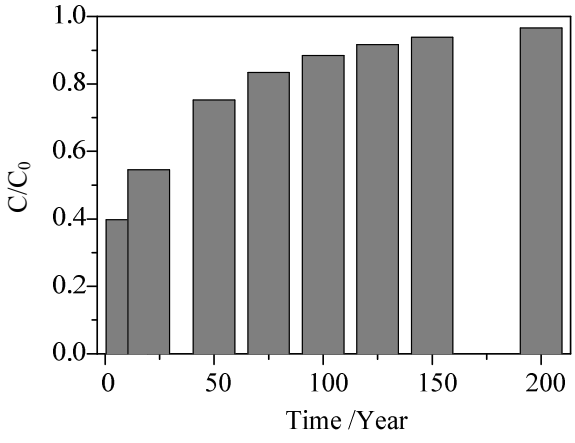
To study the influence of the hydraulic head on the migration of the contaminant, we change the hydraulic head from 1.0m to 10m and re-perform the analysis. The results are shown in Fig 3. For the hydraulic head of 1.0m, the concentration grows gradually. The initial concentration is 0.007 at year 10. The maximum concentration for Pb^{2+} is 0.042, as shown in Fig 3(a). For hydraulic head of 5.0m, the initial concentration is 0.126 at year 10. Then the concentration increase gradually during the time analyzed. The maximum concentration for hydraulic head of 5.0m is 0.54, as shown in Fig 3(b). For hydraulic head of 10m, the initial concentration is 0.4 at year 10. Then the concentration grow rapidly before year 50. After year 50, the curve goes flat because the concentration attains its critical value, which shows clearly the transportation of the contaminant is fast in the early stage of the establishment of the municipal waste landfill. The maximum concentration for hydraulic head 10m is 0.97 for Pb^{2+} at year 150.



（a）1.0m



（b）5.0m



（c）10.0m

Fig 3 The concentration-time curves for different hydraulic head

The values of concentration for Pb^{2+} is listed in Table 1. The concentration increases with the hydraulic head. At year 10, the concentration grows from 0.002 to 0.398 when the hydraulic head increases from 0.3m to 10m. At year 100, the concentration grows from 0.009 to 0.884 when the hydraulic head increases from 0.3m to 1.0m, which indicates that the hydraulic head is an important factor influencing the concentration of Pb^{2+} at the bottom of GCL.

Table 1 The values of concentration for Pb^{2+}

Year	Hydraulic head /m			
	0.3	1.0	5.0	10.0
10	0.002	0.007	0.126	0.398
20	0.003	0.012	0.187	0.546
50	0.006	0.020	0.298	0.752
75	0.007	0.025	0.360	0.834
100	0.009	0.029	0.408	0.884
125	0.010	0.033	0.449	0.916
150	0.011	0.036	0.483	0.939
200	0.013	0.042	0.540	0.965

Summery

The effects of the GM+GCL on the anti-pollution behavior of the composite liner system is studied. Parametric analysis for the Pb^{2+} and the hydraulic head are the focus of the study. The conclusions can be summarized are as follows. 1) The concentration of Pb^{2+} at the bottom of GCL increases with the increase of time. 2). The concentration of Pb^{2+} increases with the increase hydraulic head. At year 100, the concentration grows from 0.009 to 0.884 when the hydraulic head increases from 0.3m to 1.0m, which indicates that the hydraulic head is an important factor that should be considered in the design of GM+GCL composite liner system.

Study on the Morphology and Thermal Stability of Li_2SrSiO_4: Tb^{3+} Materials

Panli You

Xichang College, Xichang 615013, PR China

youpanlizb@163.com

Keywords: Luminescence, Li_2SrSiO_4:Tb^{3+}, Thermal stability, Morphology

Abstract: A series of Tb^{3+}-doped Li_2SrSiO_4:Tb^{3+} phosphors were prepared by high temperature solid state reaction. The morphology and the thermal stability of Li_2SrSiO_4:Tb^{3+} phosphors were discussed by SEM and PL measurements, respectively. The results showed that the morphology of Li_2SrSiO_4:Tb^{3+} was changed from flower-like to rod-like with increasing Tb^{3+}-doped content. Moreover, the emission intensity measured at 350 ^{0}C almost maintain with constant compared with that measured at room temperature. The results showed that Li_2SrSiO_4:Tb^{3+} phosphor might be a potential phosphor for white light-emitting diodes.

Introduction

White light-emitting diodes (LEDs) are the promising new emitting light source for common illumination because of low energy consumption, long lifetime and environment-friendliness. Tb^{3+}-doped materials have been widely applied in LEDs, FEDs as bright green emitting phosphors [[1]-[7]]. The luminescent properties of Tb^{3+}-doped phosphors could be adjusted by the turning the concentration of Tb^{3+}-doped and the matrix compositions [[8][10]].

The crystal structure of Li_2SrSiO_4 was trigonal with space group $P3_121$, Z = 3, unit-cell dimensions a = 5.02281(4) Å and c = 12.45520(8) Å, and V = 272.129(3) Å ^{3} [[11]]. The Sr atoms are located at outside space of the network and the channels formed by two [SiO4] and three [LiO4] tetrahedral units along (100) and (010). The Sr atoms are directly coordinated by eight oxygen atoms with the average bond length of Sr–O of about 2.628 Å [[12]]. The effect of Tb^{3+}-coped concentration on the crystal structure, emission peak position and intensity as well as the Commission International del'Eclairage (CIE) were discussed in our research[[4]]. However, the morphology and the thermal stability of Li_2SrSiO_4:Tb^{3+} phosphors are very importance for the practical application.

In this paper, Tb^{3+}-coped Li_2SrSiO_4:Tb^{3+} phosphors were synthesized by the solid-state reaction. The morphology and the thermal stability of Li_2SrSiO_4:Tb^{3+} phosphors were discussed by SEM and PL measurements, respectively. The result showed that the morphology of Li_2SrSiO_4:Tb^{3+} was changed from flower-like to rod-like with increasing Tb^{3+}-doped content. Moreover, the emission intensity measured at 350 ^{0}C almost retained as high as that measured at room temperature.

Experimental

The Li_2SrSiO_4:Tb^{3+} phosphors were synthesized by the solid-state reaction. Analytical reagent $SrCO_3$, SiO_2, Li_2CO_3 and high purity Tb_4O_7 (99.99 %) were used as the raw materials. The mixed powders according to stoichiometric ratio were preheated in air at 600 °C for 2 h, and then calcined at 900 °C for 4 h in a reducing atmosphere of 95% N_2-5% H_2.

The phase analysis of Tb^{3+}-doped Li_2SrSiO_4 phosphors was characterized by X-ray powder diffraction (XRD, X'Pert MPD 3kW, Philips, Eindhoven, The Netherlands). The morphology of as-prepared sample was examined by means of scanning electron microscopy (SEM，Hitachi, S-4800). Photoluminescence (PL) properties were measured by using a Hitachi F-7000 fluorescence spectrometer equipped with a 150 W-xenon lamp (excitation and emission slits: 2.5 nm; voltage:

500 V). Temperature-dependent measurements were performed using a self-made high-temperature cell for temperature above room temperature. The decay times of $Li_2SrSiO_4:Tb^{3+}$ phosphors were also obtained by time-resolved phosphor luminescence lifetime (short) model. All the properties of the phosphors were performed at room temperature.

Results and discussion

1 Crystal structure and phase analysis

Fig. 1 shows the XRD patterns of Li_2SrSiO_4:1%Tb^{3+} phosphors. The diffraction peaks were indexed by Li_2SrSiO_4 (JCPDS card No. 055–0217) and no impurity phase was detected. The result agreed with the previous reports [[4],[13]].

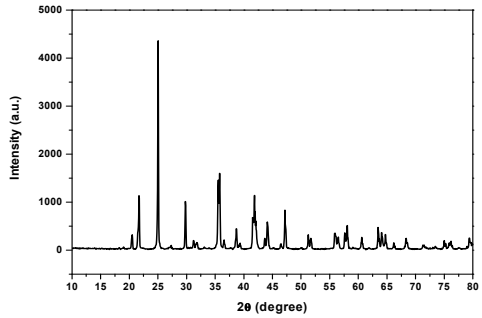

Fig. 1 The XRD patterns of Li_2SrSiO_4:1%Tb^{3+} phosphors

2 SEM analysis

The morphologies of $Li_2Sr_{1-x}SiO_4$:x Tb^{3+} (x = 1%, 4% and 20%) samples are shown in Fig. 2，respectively.

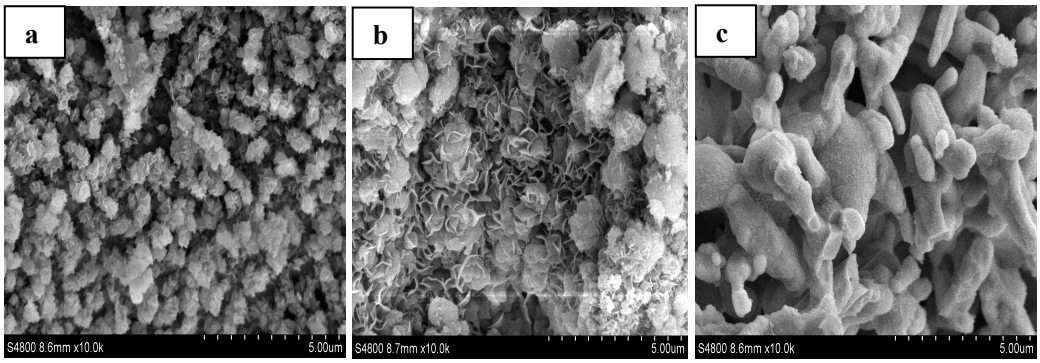

Fig. 2 SEM images of the $Li_2SrSiO_4:Tb^{3+}$, a: 1%, b:4% and c: 20% of Tb^{3+} content

It is clearly observed that the morphologies of $Li_2SrSiO_4:Tb^{3+}$ phosphors were affected by the Tb^{3+}-doped content. As shown in Fig. 2, a uniform flower-like morphology with mean size 1 μm was displayed as adding 1% Tb^{3+}- doped, and then the size of the crystalline grains was increased (about 2 μm) with using 4% Tb^{3+} content. The rod-like morphology with the diameter of about 0.5 μm and the length of 3 μm was presented in 20% Tb^{3+}- doped $Li_2SrSiO_4:Tb^{3+}$ phosphor.

The morphology change with the increase of Tb^{3+}-doped content may be contributed to the preferable growth due to the smeller ion radii of Tb^{3+} compared with that Sr^{2+} in $Li_2SrSiO_4:Tb^{3+}$ phosphor.

3 The thermal stability

The thermal stability of phosphor is required to prevent the changes in chromaticity and brightness of LEDs. The temperature-dependent luminescence properties of $Li_2SrSiO_4:Tb^{3+}$ measured in the range of 25 – 350 ^{0}C were investigated respectively, and the results were presented in Fig. 3.

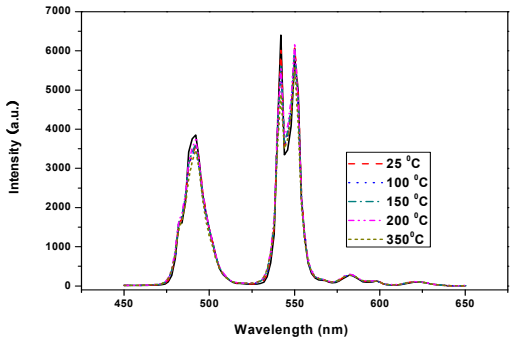

Fig. 3 The temperature-dependent emission spectra of $Li_2SrSiO_4:Tb^{3+}$

It is obviously found that the emission intensity of $Li_2SrSiO_4:Tb^{3+}$ phosphor almost keep constant with increasing the temperature from 25 ^{0}C to 350 ^{0}C. The results indicated that the thermal stability of $Li_2SrSiO_4:Tb^{3+}$ phosphor was very good suitability for use in LEDs. The excellent thermal stability may be ascribed to rigid structure of [SiO4] and [LiO4] tetrahedral network in the Li_2SrSiO_4 host lattice [[12],[13]] as well as the transition feature of Tb^{3+} .

4 Decay lifetime

Effect of Tb^{3+}-coped concentration on the decay time of $Li_2SrSiO_4:Tb^{3+}$ was investigated. The decay curves and fitted lifetimes of Tb^{3+} emission (542 nm) under excitation at 243 nm for $Li_2Sr_{1-x}SiO_4:xTb^{3+}$ (x = 1%, 4% and 20%) were exhibited in Fig. 4, respectively.

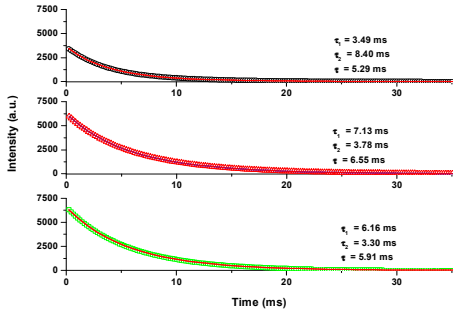

Fig. 4 The decay curves and the fitted lifetime for $Li_2Sr_{1-x}SiO_4:xTb^{3+}$ (x = 1%, 4% and 20%), respectively.

The decay curves could be well fitted by a bi-exponential function [[14]]:

$$I(t) = A_1 \exp(-t/\tau_1) + A_2 \exp(-t/\tau_2) + I_0 \quad (1)$$

Where I_0 and I are the luminescence intensities at time 0 and t, respectively; τ_1 and τ_2 are two components of the luminescence lifetime, and A_1, A_2 are the fitting parameters. Using equation (1), the fitting values in $Li_2Sr_{1-x}SiO_4:xTb^{3+}$ (x = 1%, 4% and 20%) are (τ_1 = 3.549 ms，τ_2 = 8.40 ms; A_1 = *2935.93, A_2 = 705.85*),（τ_1 = 7.13 ms, τ_2= 3.78 ms; A_1 = *4468.42, A_2 = 1765.58*）and （τ_1 = 6.16 ms, τ_2 = 3.30 ms; A_1 = *5588.79, A_2 = 1011.93*）corresponding to 1%, 4% and 20% of Tb^{3+}-doped concentration, respectively.

The two lifetime τ_1 and τ_2 represent the two processes of radiative transition and energy transfer in $Li_2Sr_{1-x}SiO_4:xTb^{3+}$ phosphors. The average lifetime was τ = 5.29, 6.55 and 5.91 ms in turn for 1%, 4% and 20% Tb^{3+} in terms of the following equation [[15]].

$$\tau = (A_1\tau_1^2 + A_2\tau_2^2)/(A_1\tau_1 + A_2\tau_2) \quad (2)$$

The decay lifetime varied with increasing Tb^{3+}-doped amount might be explained by the non – linear resonant energy transfer theory reported by Hayakawa [[16],[17]]. For the lower Tb^{3+} doped content, the decay lifetime increased with increasing the concentration of Tb^{3+} dopant. However, for the higher Tb^{3+} doped amount, the decay lifetime decreased with increasing the concentration of Tb^{3+} dopant due to non – linear resonant energy transfer.

Conclusion

The Tb^{3+}-doped $Li_2SrSiO_4:Tb^{3+}$ phosphor was synthesized by high temperature solid state reaction. The morphology, the thermal stability and decay lifetime of $Li_2SrSiO_4:Tb^{3+}$ phosphors were discussed by SEM and PL measurements, respectively. The results showed that the morphology of $Li_2SrSiO_4:Tb^{3+}$ was changed from flower-like to rod-like with increasing Tb^{3+}-doped content. Moreover, the emission intensity almost maintained a constant as increasing the temperature from 25 ^{0}C to 350 ^{0}C. The decay curves could be well fitted by a bi-exponential function, and the corresponding decay lifetime in $Li_2SrSiO_4:Tb^{3+}$ phosphor was 5.29 ms, 6.55 ms and 5.91 ms for 1%, 4% and 20% Tb^{3+}, respectively. The results showed that $Li_2SrSiO_4:Tb^{3+}$ phosphor can be a potential phosphor for white light-emitting diodes.

Keywords: halloysite silane coupling modifying adsorption CO_2

Abstract. The natural halloysite as the main raw material, removing the kaolinite, the quartz, feldspar and other impurities through purification. The purified halloysite was roasting activation pretreatment, in order to enhance surface porosity and reaction activity, and then was made of halloysite composite by modifying through the use of silane coupling agent. The samples were characterized by XRD, FESEM, BET, FT-IR and other chemical analysis method. The weight percentage of CO_2 which were adsorbed by the modified halloysite increased from 3.13% to 13.92%.

Introduction

Recently, global warming and a series of environmental problems caused by a great amount of CO_2 have become the focus in the world[1-2]. Simultaneously, CO_2 is a kind of carbon resource which used as a synthetic organic compounds and fuel for various aspects of national life[3-4]. No matter committed to reducing the content of CO_2 in atmosphere, or to use,separation and recovery of CO_2 is a crucial step.

Now, the methods of trapping and separating CO_2 include adsorption method, membrane separation method, solvent adsorption method and low temperature distillation method[5-6]. Adsorption is a kind of very promising method of separating CO_2[7]. Recently, the popular porous solid adsorbents of CO_2 include metallic-rectangular organic compounds[8-9], zeolites molecular[10], amino-modified mesoporous materials[11-12] and so on. Currently the metallic-rectangular organic compounds are still in research phase and have a certain distance from the large-scale industrial application; zeolites molecular have large adsorption amount of CO_2 at room temperature and good adsorption selectivity, but the capability of adsorbing CO_2 will decrease rapidly under trace water or SO_x conditions; amino-modified mesoporous material receive more and more concerns because of its fine adsorption selectivity in the presence of water. However, the research more of that are amino-modified mesoporous materials, amino-modified resin and amino-modified activated carbon, studies about CO_2 adsorption by natural mineral materials were not reported.

In this paper, halloysite was thermal activated to enhance its surface activity, then choice of silane coupling agent on the impregnation and modification to produce natural mineral based solid alkaline sorbent. The structure, thermal property, and pore size distribution of materials in different stages were characterized by XRD, FT-IR, TG/DSC, BET, and the CO_2 adsorption capacity of the modified material were determined by gravimetric analyzer.

Experimental

Raw and Reagent. Halloysite raw ore was provided by lincang Yunnan Province, r- aminopropyl triethoxy silane, polyacrylamide, and hexametaphosphate were purchased from Compton, Guali fine chemical plant in xiaoshan Hangzhou, and haijing fine chemical plant in hebei Tianjin separately .

Activation of halloysite. (1) Purification of halloysite. Steps of purification: adjust the system's pH value, added a certain amount of dispersant, centrifuging under specified speed, and then obtained the relatively pure **7Å** halloysite product. Technological process: ① Halloysite raw ore was

assigned to slurry which the weight ratio was 15%, and then mixed by high-speed stirrer at rotating speed 8000r/min for 1 h. ② Halloysite slurry was sift by 100 mesh screen after dispersed uniformly. ③ The below-sift slurry standing for 6 h, the suspension in upper layer was collected by centrifuge, and drying 12 h at 95 ℃, scattered by universal grinder. ④ The power in step ③ was assigned to slurry, adjusted its pH value, and then added appropriate content dispersant, mixed by high-speed stirrer for 2 h. ⑤ Placed suspension at centrifuge at a certain speed, removed the sediment in lower layer, placed suspension in upper layer at centrifuge at the speed of 3800r/min for 5 min. ⑥ The sediment in step ⑤ were drying 12 h at 95 ℃, and then obtained high purity 7Å halloysite product.(2) Calcination of halloysite. A certain amount of purified halloysite was placed at SX2-1-10 electric furnace in a certain temperature for 2 h, cooled to room temperature,and made the phase, morphology and elemental analyses.

Preparation of modified halloysite. 100mL ethanol which contain 2mL water placed in conical flask, added 3 mL γ-aminopropyltriethoxysilane, dispersed for 20 min by ultrasonic apparatus, added 2 g halloysite power after calcined for 2 h, mixing and refluxing in water bath in 80 ^{o}C for 6 h, filtered,and then the samples of halloysite modified by silane coupling agent were prepared after baking in 50 ℃ and grinding.

Performance testing of CO_2 adsorption. A certain amount of need checking samples were placed at sample chamber. Pumped in nitrogen gas for 60 min, flow rate at 50 mL/min, and hearting, hearting rate at 10℃/min, heated up to a certain temperature(70~80^{o}C), activated in vacuum condition (vacuum pressure:40KPa), and then cooling, pumped in CO_2(flow rate at 40mL/min) when the system at room Temperature, and stoped at the standard atmosphere(100KPa), adsorbed continuously for 2 h, when adsorption reach to be saturated, reaction finished.

Assuming that original quality of samples were m, the mass percentage reduced by a in the first stage and increased by b in the second stage, then the mass percentage of CO_2 adsorption:

$$\frac{\text{Quality after adsorption}}{\text{Quality before adsorption}} = \frac{m \times b}{m \times (1-a)} = \frac{b}{1-a} \qquad \text{(Type1)}$$

Result and discussion

Activation of halloysite. Fig.1 shows the XRD patterns of crude and pure halloysite. It showed that many diffraction peaks of impurities such as quartz (some characteristic peaks at 0.420nm and 0.3332nm), feldspar (some characteristic peaks at 0.37746nm, 0.34662nm and 0.42169nm), gibbsite (some characteristic peaks at 0.4834nm and 0.3562nm) were appeared in the XRD patterns of crude and pure halloysite. The purity of halloysite after purified was above 98%, and its characteristic peaks appeared at 0.73971nm, 0.44554nm and 0.36429nm. The type of halloysite in lincang Yunnan Province was 7Å (7.25~7.40Å). And it also showed that the polarization of diffracted beams of (02) and (11) were stronger than that of (002) while smaller than that of (001) under the temperature between 20 ℃ and 30℃, $I_{(02)} \sim \frac{I_{(001)} + I_{(002)}}{2}$, there is obvious division in diffracted beams of (13) and (20). This deposit should be classified as the type of coexistence with kaolinite and halloysite[16-17].

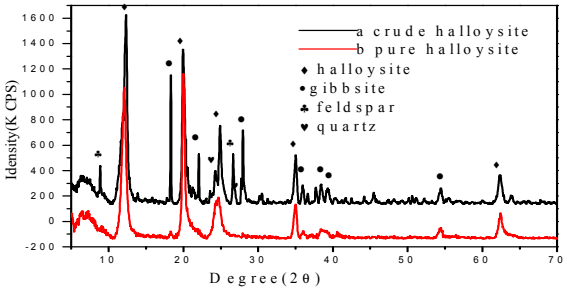

Fig.1 The XRD of crude and pure halloysite

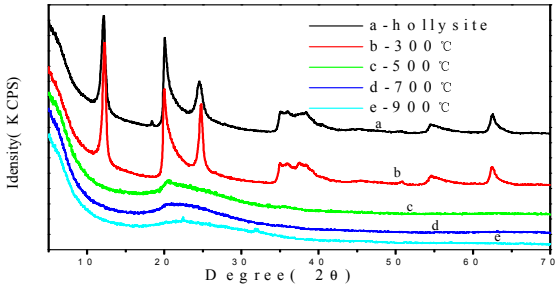

Fig.2 The XRD of halloysite at different temperatures

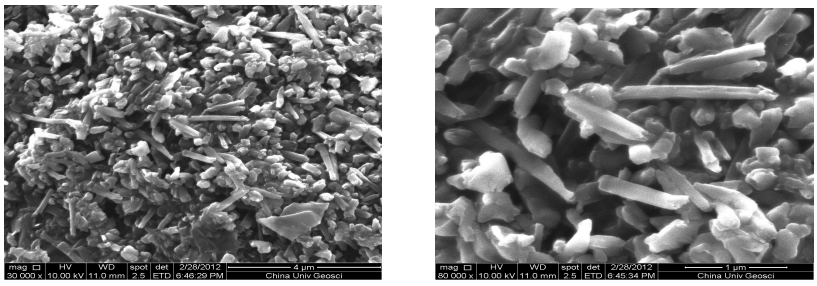
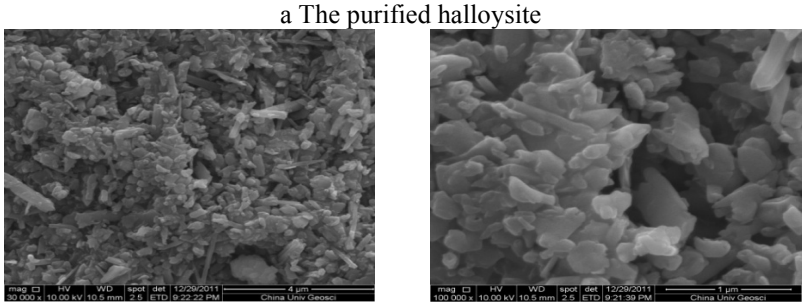
Fig.2 shows the XRD spectrum of halloysite which were calcined at different temperature, a was x-ray diffraction patterns of halloysite, b, c, d and e were halloysite calcined at 300℃, 500 ℃, 700 ℃, and 900 ℃ for 2h separately.

Fig.2 shows that adsorbed water was disappeared, nanometer channel and structure become fatherly dredging and close respectively, which lead to diffraction peaks shifts of (001) and (002) toward high angle, peak pattern become sharp and relative intensity was enhanced. There wasn't obvious diffraction peak but amorphous state when the calcining temperature was above 500 ℃. So the future calcination test experimented at 300 ℃.

Fig.3 shows the FESEM picture of purified halloysite and halloysite calcined at 300 ℃ for 2h. Picture a and b were respectively the FESEM picture of purified halloysite and halloysite calcined at 300 ℃ for 2h.



a The purified halloysite



b The calcined halloysite under 300 ℃for 2h

Fig.3 The FESEM of the purified and calcined halloysite

The SEM analysis shows that surface morphology of halloysite original sample were tubular,the length of the tube is 0.5-2um. When calcined at 300℃, the halloysite only removed adsorbed water and crystal water that have no effect on the basic structure. The microstructure had little change and still keep tubular structure, but the length of the tube was 0.3-1um shorter. The fracture of the tubular structure would inevitably result in specific surface area and pore volume increase, and then enhanced the adsorption property of samples, which will conducive to subsequent trials.

Preparation of modified halloysite. Halloysite after activation, although the porosity and the active center density can be increased, enhanced the interaction force with the adsorbed substance, the selectivity of adsorption can not effectively to change. In order to improve the selectivity, halloysite was activated by silane coupling. The infrared spectra of hollysite modified by γ-aminopropyltriethoxysilane is showed in Fig.4, a is the calcined hollysite; b is modified hollysite; c is the silane coupling.

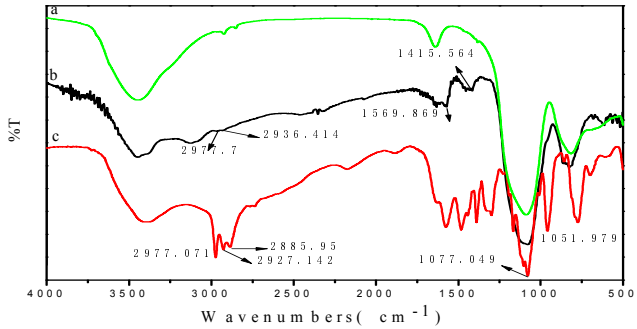


Fig.4 The IR analysis of halloysite modified by silane coupling

The curve a in Fig.4 shows that the bands at 2977.07 cm^{-1} and 2885.95 cm^{-1}, 2927.14 cm^{-1}, 1077.049 cm^{-1} were stretch vibration absorption spectra of C-H bond of -C-CH_3, C-H bond of -C-CH_2-C-, Si-O bond of γ-aminopropyltriethoxysilane respectively.

Fig.4 shows that compared with the infrared spectra curve of unmodified halloysite, the modified by γ-aminopropyltriethoxysilane has extra characteristic absorption peaks 2977 cm^{-1}, 3936 cm^{-1}, 1569 cm^{-1}, 1415 cm^{-1} and 1051 cm^{-1} , the characteristic absorption peaks 2977 cm^{-1} and 3936 cm^{-1}, 1569 cm^{-1}, 1415 cm^{-1} created by the vibration of C-H bond of -C-CH_2- and -CH_3- respectively. This means that there were -C-CH_2- and -CH_3- in modified halloysite samples. The characteristic absorption peaks 1051 cm^{-1} created by the vibration of Si-O bond.

Fig.4 also shows that absorption peaks created by the vibration of Si-O was 1051cm^{-1}, in infrared spectra curve of γ-aminopropyltriethoxysilane. While, in the infrared spectra curve of modified sepiolite, absorption peaks created by the vibration of Si-O bond are 1077 cm^{-1}. The bands between 400-1100 cm^{-1} were stretch vibration absorption spectra of Si-O bond, compared to other two peaks, the peak intensity became stronger, the peak pattern became wider.

Therefore, under the above experimental condition, there was alkyl group in the modified halloysite samples, and the vibration absorption enhanced, γ-aminopropyltriethoxysilane was successfully grafted onto the surface of halloysite. The organic modification of halloysite was realized

Tests on CO_2 adsorption properties

(1)Tests on specific surface area and pore volume

Table 1 lists the pore parameters of calcined halloysite and calcined halloysite modified by silane coupling agent.

Table1 The pore parameter of calcined halloysite and modified by silane coupling

sample	BET(m^2/g)	V_{sp}（cm^3/g）	D_p（nm）	S_{BET}（m^2/g）		V_{sp}（cm^3/g）	
				0-2nm	2-50nm	0-2nm	2-50nm
calcined	37.0370	0.109641	11.84320	0.643	33.561	0.0003100	0.1037
modified	29.1663	0.089684	12.29967	2.123	25.337	0.000988	0.083768

Table 1 shows that the specific surface of modified halloysite decreased from 37.0370 m^2/g to 29.1663 m^2/g. The pore volume of modified halloysite also decreased from 0.109641cm^3/g to 0.089684cm^3/g, while the pore size of modified sepiolite increased from 11.84320nm to 12.29967nm.

After modification, both pore area and pore volume of halloysite are larger than that of before in the micropore scope of 0 to 2 nm. Pore area of halloysite increased from 0.6430m^2/g to 2.123m^2/g, and pore volume of halloysite increased from 0.0003100cm^3/g to 0.000988cm^3/g. While, in the micropore scope of 2 to 50 nm, pore volume of modified halloysite decreases from 0.1037cm^3/g to 0.083768cm^3/g, pore area of modified halloysite decreases from 33.5610 m^2/g to 25.337m^2/g. The increasement of surface area and volume of modified halloysite contributes to the improvement of adsorbing capacity of CO_2.

(2)Tests on CO_2 adsorption properties. Fig.5,6 respectively for sample adsorption CO_2 thermogravimetric curve, stage a on behalf of vacuum pumping stage, b stage as CO_2 adsorption.

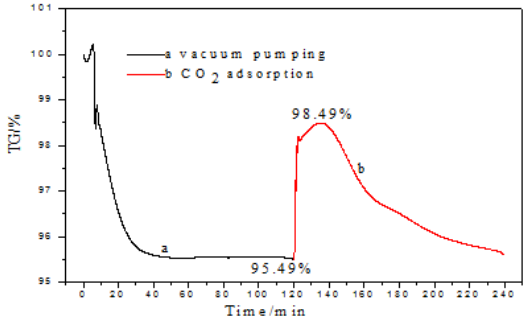

Fig.5 The thermogravimetric curve of calcined halloysite

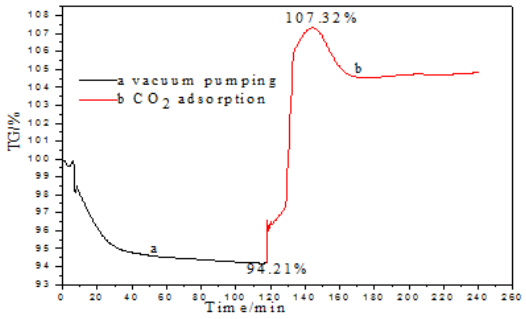

Fig.6 The thermogravimetric curve of modified halloysite

As you can see from Fig.5, in the a stage, quality changes continuously decreased to 95.49%; b stage, the mass percentage of samples rapidly increased to 98.49%, the maximum adsorption capacity of CO_2, followed by a fall and rise, basically in the dynamic adsorption equilibrium. See from Fig.6, in the a stage, the decline in the quality of samples have small fluctuations, the percentage dropped to

94.21%; in the stage of CO_2 adsorption, the percentage quickly up to a maximum of 107.32%, then decreased, and then in a platform, the degree of quality changes very little.

By using Type 1, the mass percentage of CO_2 adsorption had been calculated to be 3.13% and 13.92% respectively pre and post the modification.

Conclusion

(1) After purification, there is a apparent decrease in impurity peaks of gibbsite, quartz, feldspar and illite. Refined halloysite sample with the purity over 98% are obtained. (2) By the XRD analysis of halloysite which were calcined at different temperature, halloysite should be calcined at 300 ℃. When calcined at 300 ℃ for 2h, the microstructure had little change and still keep tubular structure, but the length of the tube was 0.3-1um shorter. The fracture of the tubular structure would inevitably result in specific surface area and pore volume increase, and then enhanced the adsorption property of samples,which will conducive to the further organic modification. (3) Halloysite modified by ethanolamine acetate ionic liquid silane coupling shows a decrease in pore area and pore volume and an increase in pore size. The adsorption amount of CO_2 at room temperature and pressure increases from 3.13% to 13.92%, showing a great improvement of the adsorbing capacity of CO_2 in modified halloysite.

Keywords: 2Cr13 Martensite Stainless Steel,City Atmosphere,Initial Atmospheric Corrosion, electrochemistry

Abstract: Used electrochemical tests and the natural atmospheric exposure experiment to study initial atmospheric corrosion of 2cr13 steel in Guiyang city . Measured impedance spectrum curves and polarization curves of experimental steel in the local rain medium.Weight method measured the corrosion rate. The results showed that the exposure period of 0 to 60 days, with longer time, the corrosion current increased firstly then decreased, and the corrosion current decreased after the firstly increased. Impedance spectra showed that passivation process was controlled by the electrochemical reaction. Measured the corrosion rate of 0.000280 ~ 0.000280 mm/a, which belongs to the corrosion level 2 - very corrosion resistance.

1.Introduction

Martensite stainless steel is a kind of steel that can be achieved by different heat treatment process to adjust its mechanical properties of stainless steel. Typical brands of martensitic stainless steel are Cr13 and Cr16 type,etc. In recent years, the martensitic stainless steel are used in the manufacture of oil well pipe under the environment of high temperature and high pressure oil fields, a lot of researches on adding alloying elements into Cr13 stainless steel to improve its CO_2 corrosion resistance. Some studies showed that the composition has the characteristics, such as containing chromium more than 12% , without nickel or containing small amounts of nickel (2.0%) , high carbon (generally more than 0.1%)[1], resulting in the weak corrosion resistance of martensitic stainless steel in chloride or sulfide medium , only suitable for mild corrosion environment, such as atmosphere and water, etc. With the development of urban industry,higher requirements of corrosion resistant performance of martensitic stainless steel are put forward. Therefore, this paper, electrochemical behavior of the initial atmospheric corrosion of 2Cr13 steel in Guiyang city atmosphere, is necessary. It will provide theoretical basis for the application of life and production .

2.Experiment Materials and Methods

2.1 Experiment Materials. Material for experiment was bought from market as Φ 100 mm stainless steel bar, chemical compositions (mass %) are shown in table 1 below:

Table 1 Chemical composition of stainless steel (wt%)

sample	C	Cr	Ni	Mn	Si	S	P
2Cr13	0.2	12.59	0.15	0.57	0.19	0.006	0.021

The samples of electrochemical experiments and atmospheric exposure test were cut by electric spark numerical control line cutting machining. Electrochemical sample were cut into 10 mm x 10 mm x 5 mm, the samples connected to conductor by soldering with tin.Seal the samples with epoxy resin and curing agent whose mass ratio is 4:1, only to set aside a 10 mm x 10 mm of working surface. Size of atmospheric exposure samples were about 50mm x 30 mm x 4 mm.

After the preparation of all samples were completed, the samples need be sanded and polished. Then dry them after cleaning with deionized water, acetone and ethanol.

2.2 Experiment Methods. This experiment adopts the electrochemical and natural environment exposure test methods [2] to study the early atmosphere corrosion.

In France Bio-Logic VSP electrochemical workstation. Polarization curves and electrochemical impedance spectroscopy curves were obtained by potentiodynamic scanning method. Polarization curves scanning were ranged -0.7V~1.9V(SCE) and simulated with Tafel fit. The frequency range of alternating current impedance was 100 KHz ~ 10 mHz, and AC excitation signal amplitude was 10 mV, then equivalent circuits were simulated with Zview fit.Corrosive medium was Guiyang local rain water. Using three electrodes system, the working electrodes were 2Cr13 stainless steels.

The samples and ground plane were 45 ° on the exposed rack. Exposure experiment was started since November 27, 2012, and the exposure periods were 15 days, 30 days, 45 days and 60 days respectively. Exposure site was on the top floor of a laboratory in Guiyang; the environment parameter of exposure scene was as follows: the average temperature of 11 ℃, the average monthly humidity of 90%, monthly rainfall for 13 days.

3.Results and discussion

3.1 the polarization curve. As shown in figure 1, the polarization curves with different test periods of the experimental steel made parallel movement at different degree.Cathode area appeared oxygen reduction limiting current platform, and anode area presented pre- passivation phenomenon. In different curves,just current density and the corrosion potential were in different sizes.

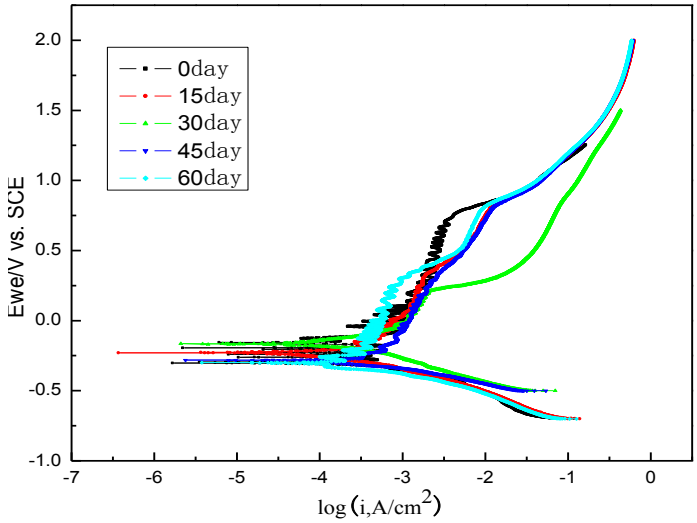

Figure 1 Polarization curves of experimental steel with different exposure periods in Guiyang city atmosphere

Fit the polarization curves by Tafel, the results shown in table 2. It showed that under different exposure period, polarization curves of experimental steel all had passivation area with a little difference. It told that in the local rain water medium, the experimental steel can be passivation. Corrosion current density *Icorr* is used to determine the electrochemical corrosion reaction speed.The greater the *Icorr* was, the faster the corrosion happened. In general, lower the nature corrosion potential *Ecorr* was , the greater the corrosion speed would be[3]. The figure 1 and table 2 showed that 15 to 45 days exposure period, with longer time, the corrosion current density increased, the easier the corrosion would be.To 60 days, *Icorr* reduced and the corrosion slowed down. Corrosion current *Icorr* was below 0.4 μA, and the corrosion potential is closed to positive.Therefore,the experimental steel in local rain medium had good corrosion resistance.

Table 2 Fitting results of stainless steel polarization curve with Tafel

Exposure period	0 day	15 day	30 day	45 day	60 day
E_{corr} (mV)	-161.561	-235.787	-167.060	-272.33	-253.890
I_{corr} (μA)	0.120	0.166	0.275	0.363	0.119

3.2 the polarization curve. The figure 2 showed that ac impedance spectrum with different test period of experiment steel in the local rain water had similar characteristics, and they were composed of high frequency single capacitive reactance arc. The greater the radius of the semicircle of the capacitive reactance were , the bigger the capacitive reactance were [4]. The characteristics of the impedance spectrum showed that passivation process was controlled by the growth and dissolution of the surface passivation membrane. The whole process was controlled by electrochemical reaction. Without the atmospheric corrosion, charge transfer resistance was the biggest. In 15-45 days, the capacitive reactance arc radius decreased; the charge transfer resistance decreased, and its corrosion resistance ability in gradually declined. But when the exposure time reached 60 days, the capacitive reactance arc radius increased again, which showed that the corrosion resistance improved.

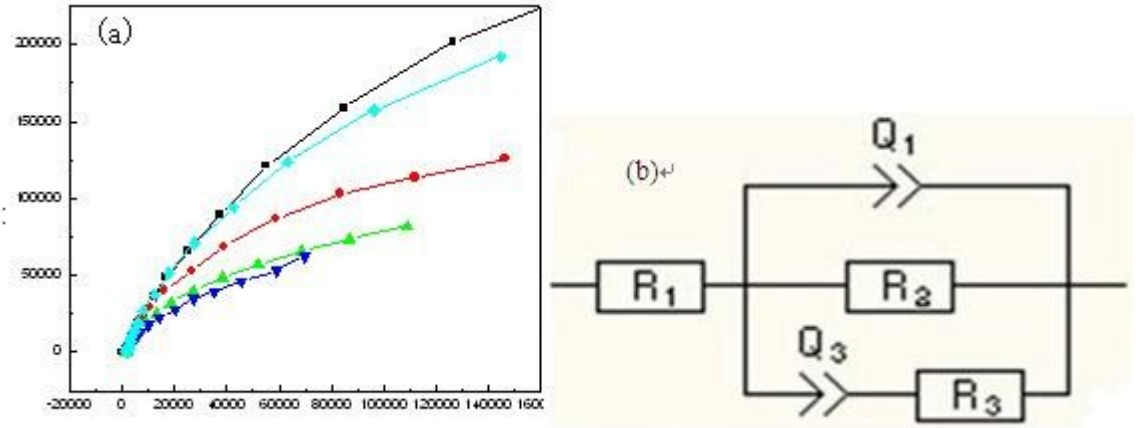

Figure 2 Impedance spectrum curves of experimental steel in different exposure period in Guiyang atmospheric environment (a) the equivalent impedance matching circuit (b)

Like table 3 the solution resistance R1 didn't change too much. Charge transfer resistance R2 of system was very big.This kind of high impedance was supposed to produce a passivation membrane [5]. In 15-45 days, as the atmospheric exposure period increased, the charge transfer resistance R2 decreased. Because samples adsorbed intermediate from the air when the exposure time be longer, and electrolyte concentration, solution conductivity increased. When exposure period reached to 60 days, the impedance resistance increased many and its corrosion resistance improved. This is because the experimental steel surface formed a protective membrane layer.

Table3 Fitting results of impedance spectrum curves of 2Cr13 in Guiyang atmospheric environment

Exposure period	0 day	15 day	30 day	45 day	60 day
R1*(0hm)*	1106	1464	1403	1514	1559
R2*(0hm)*	688597	238089	135685	94817	535576

3.3 corrosion rate of natural environment exposure test

Table 4 The corrosion rate of the experiment steel under different test period

Exposure period (day)	15	30	45	60
corrosion rate (g/㎡ h)	0.0014	0.000389	0.000286	0.000248
The average corrosion depth (mm/a)	0.00158	0.000439	0.000323	0.000280

From the table 4, with the growth of the exposure time, corrosion rate gradually reduced. Within 30 days，the corrosion rate firstly increased with exposure time increased, then corrosion rate reduced very significantly. When exposure period was more than 30 days, corrosion rate changed little,which explained that a relatively stable phase formed in the rust layer with the exposure time increasing . Based on the tenth level standard of metal corrosion resistance in the

former Soviet union [6]， when the exposure period was more than 15 days, the experimental steel was completely corrosion resistant in Guiyang atmosphere. When exposure period was 15 days, it belonged to level 2 -very corrosion resistance.

4. Conclusion

(1) When the exposure period was 0 to 60 days, with longer time, the corrosion current increased firstly then decreased. The corrosion rate is largest in 45 days.
(2) The impedance spectrum showed that passivation process was controlled by the electrochemical reaction,and the charge transfer resistance decreased firstly, then increased with the increase of exposure period.
(3) weight method measured the corrosion rate 0.000280 ~0.00158 mm/a in Guiyang atmospheric environment.It belonged to the level 2 - very corrosion resistance.

Keywords: flax, dyeing properties , fiber modification , improvement methods

Abstract. Flax fiber moisture, permeability, with good wearability. But the flax fiber dyeing performance is poor, light color , there will be color difference, dyeing unequal phenomenon . Through the analysis of the performance of flax fiber dyeing , tells the story of flax fiber dyeing difficulties. This paper introduces the urea, bulking agent, sodium hydroxide, ultrasonic, rare earth and other methods to improve the dyeing properties of flax fiber.

Introduction

As people 's awareness of environmental protection , natural fibers back into the spotlight . Flax fiber moisture absorption, good ventilation , high strength , abrasion resistance, and less dust , easy to clean , with good gloss , comfortable, cool, popular with the international market [1]. Compared with the ramie, hemp , Apocynum , linen fabric style of primitive simplicity, elegant, wearing more comfortable, better serviceability. But flax fibers are also inadequate , fiber toughness, rough, impurity more, in the dyeing process, the fabric color is not bright light,and poor color fastness, , and sometimes there will be color difference[2] . It has been conducting research on flax fibers modified, to solve the problem of poor performance issues flax fiber dyeing.

The difficulties of dyeing of flax fiber

The inherent factors of the difficulties of dyeing of flax fiber are that the flax fibers have a high degree of crystallinity and a high degree of orientation, with more closely structure, the inclination is small, and non-fiber ingredient is high. Flax fibers in the microstructure, the crystalline region is larger than the area of the amorphous region, the smaller the space occupied by the dyeing of the dye molecules can. Meanwhile, the high degree of orientation also hinders the penetration of dye molecule.[3]

Flax fiber contents of at least 5% lignin, lignin is very difficult to be dyed. Removal of lignin in flax roving chemical degumming processes are usually two ways: one is the low temperature chlorination, the other is a high-temperature sulfonation. Regardless of the method, the removal of lignin is less than 40 %. Therefore, after retting flax fiber net no other reason except lignin is difficult to be dyed.[4]

Hemp single fibers bonded together by pectin cross each other, is very difficult to staining. Single flax fiber is very short, only 11 ~ 25mm, cannot be directly spinning. Therefore, to ensure the spinnability and yarn strength, degumming pectin is not completely removed when carrying out the roving. Roving degummed residual pectin spun fibers together, so it is not easy to dip dyeing uniformity, prone to white core yarn and yarn color flowers. [4]

Chemical reactions of flax cellulose mostly occur in the three free hydroxyl group and an aldehyde group at the end of macromolecules. The hydroxyl group is reacted with an inorganic acid-base, and the aldehyde group’s chemical reactions are the dye was adsorbed moisture, oxidation, esterification, etherification and graft reaction. During the formation of the flax roving process to chemically degumming, strong oxidation of serious damage to this process the molecular structure of cellulose hydroxyl and aldehyde groups, thereby reducing the dye is covalently bound to the cellulose and the formation conditions.[4]

The methods of improving the dyeing of flax fiber

To solve the problem of poor dyeability of flax fiber, at home and abroad have been modified flax fiber research,to improve its dyeing properties. The so-called modified flax fiber for flax fiber

is inadequate, chemical or physical methods for its processing, to get some special properties. After modification of hemp fiber processing, improved dyeing properties of the fabric, fabric color is bright, shades affordable.The main method of hemp fiber modification are the following

The urea pretreatment

Put the linen cloth into a certain concentration of urea solution for the pretreatment before staining under the condition of high temperature, it can improve the levelness and dyeing percentage of the linen cloth, and at the same time it does not reduce the dyeing fastness. To a certain extent, it solves the problem of staining difficulties and uneven dyeing on linen cloth. Urea reacts with linen cloth, which makes fiber swell and become more rough on the surface[5].During the dyeing process, urea improves the adsorption capacity to dye of the linen cloth, and increases the chance of reaction between dye and fiber, then improves the dyeing rate and the dyeing depth. After urea modified flax fiber strength decreased slightly, but the decrease is tiny. The reason for the fiber strength decrease of flax fiber is that some fiber on the surface becomes swell and broken after urea treatment.[6].Though the fiber strength decreases slightly, the dyeing properties improves a lot.

The expanders pretreatment

After adding the liquid expanders, the surface tension of the solution will reduce ， the surface area is easy to expand, adding solid expanders, expanders are directed adsorbed on a solid surface. When the expansion agent adsorbed on solid surfaces generally, although reducing the surface tension of the solid, the surface area is difficult to expand. Flax fibers are composed of a linear polymer, the surface area is relatively large, very elongated shape than the flexibility of the molecular chain is preferred. After adsorption flax fiber bulking agents, surface tension reduction, the fiber surface becomes easy expansion, easy to stretch the length of the fabric becomes plump and fluffy。Adsorbed on the fiber surface expansive role of the stronger, more able to reduce the surface tension of the fibers, the better the effect of expansion. Expanders can use flax fiber volume expansion in the same weight, and can significantly improve the absorption characteristics of flax fiber.

Beam expanders unused surface modified flax fiber is smooth, the fibers are arranged between the fiber bundles tightly. Expansion of the role of the use of bulking agents for processing flax fiber, flax fiber bundle expands, the gap between the fiber bundles of fibers increases, the loose arrangement improves the surface roughness of flax fiber to increase its gross efficiency, this facilitates dye adsorption flax fibers in the dyeing process, help to improve the probability of occurrence of dye staining reaction with the fiber, thereby increasing the depth of staining when dyeing. [7]

Dyeing on ultrasonic environment

In the absence of ultrasonic environment, flax fiber dyeing rate is low. In the presence of ultrasonic, as the ultrasonic cavitations effect can make bubbles in the flax fiber left from fiber surface, and disappear quickly. Because ultrasound provides additional momentum to the dye molecules, it is not only can overcome the repulsive force between each other, but also advantageous to the contact between the dye and fiber, and improve the adsorption rate of the dye on the fiber surface. Ultrasound can improve the affinity of reactive dyes to flax fiber, accelerate the absorption of fiber to dye, improve the dyeing rate of dye and the amount of color of the fiber.

But when the ultrasonic frequency reaches 40 kHz, the ultrasonic cavitations effect is too big, and make the friction heat between the fibers, temperature rise, and the adsorption ability of dyeing liquid on the contrary will decline [8].In a relatively short period of time, the ultrasound dyeing is often can achieve even greater effect than that of normal dyeing. When dyeing, if extend the effect time of the ultrasonic, dyeing rate can slow increase; if Increase the frequency of ultrasonic, the ultrasonic can promote the efficiency of dyeing more obvious. The frequency is to higher , the acoustic cavitation in a relatively short period of time is more obvious. The ultrasound dyeing

technology with energy conservation and emissions reduction, shorten processing time and improve the performance of textiles, and many other advantages, it is an important way to improve the flax fiber of dyeing performance.

The alkali treatment

Alkali treatment is mainly generated by the principle of alkaline cellulose flax cellulose with high concentration sodium hydroxide solution. Because of the alkali treatment process to generate alkali cellulose is an exothermic process, so the alkali treatment were completed at normal atmospheric temperature. Flax fiber after sodium hydroxide modified, either dyeing, fabric dyeing rate are improved obviously[2].General with the increase of the concentration of sodium hydroxide, dyeing rate increases, especially vat dye, fabric dyeing rate increased significantly. Also, sodium hydroxide and flax cellulose, flax fibers swell phenomenon, The fiber elastic, with silk, improve the capillary effect and increase the permeability of fiber fiber, The hemp fiber improves elasticity and softness, so that enhance the crease resistance of flax textile. In addition, the flax fibers modified by sodium hydroxide, the crystallinity and orientation degree increases with the concentration of sodium hydroxide and basic linear decline, The polymerization degree of the fiber in alkali treatment decreased rapidly at the beginning, then tends to a constant value. The degree of fiber aggregation, crystallinity and orientation degree increases with the increasing of the concentration of sodium hydroxide and decreased. Dyeing performance of linen fibers decreased with increasing crystallinity, degree of orientation and improved.

Application of Rare Earth in flax dyeing

Rare Earth can be divided into by sulfuric acid complex salt solubility: Light rare earth, rare earth and heavy rare earths. Textile industry is generally based on rare earth chloride. This rare earth chloride ions comes into the flax fibers, then the original arrangement of the fibers is changed, reducing the degree of orientation and crystallinity of the flax fibers, increasing gap between the fibers, dye relatively easily access to fiber interior. Further, a feature of contact of rare earth ions can make the rare earth dye nitrogen, oxygen react to form an ionic organic ligand bond. But complexion ability of rare earth ions is weak. Not all fiber can be coordinated, only partially replaced. Part of the rare earth ions complex with flax fiber, on the one hand has enough acceleration effect, on the other hand combined with fiber, and become the new dye uptake of dye seat. Both in combination with the dye flax fiber and rare earth ions and improve the uptake rate of the fiber. After adding rare earth flax dyeing process, not only can improve the dyeing rate and vividness of dyes and dye to make different dyes of half time approaching. This improves compatibility linen fabric and leveling effect, rare earths used in the dyeing process flax not only improve the flax colored rate fixation rate, But also increased the vividness of linen fabric. Application of rare earth-stained, stained linen for solving difficult problems on providing new solutions for promoting the development of flax textile industry has very important significance.[4,9,10]

The new dye sodium copper chlorophyll

In recent years, there have been reports that some of the synthetic dyes dyeing textiles will cause serious harm to people's health and human living environment.，which forced some new dyes, extracted from natural plant pigment, non-toxic harmless, is the real green dye. And the extraction of plant dyes also has some health care functions. The fabrics dyed by plant pigments are natural shapes, colors, and not easy to fade; There are some natural pigment also has the insect, the role of sterilization, Some clothes such as underwear, children's clothing, the sensitivity of towels, bedding, particularly need these functions. Development of plant dyes are catering to the modern people to return to the nature of consumer psychology. Chlorophyll is a plant widely spreading in the pigment chlorophyll, but poor stability, make its application limited. However, chlorophyll derived from sodium copper chlorophyll stability is relatively high, the water solubility is very good. It is a bright green color pigment. The studies show that, in the dyeing process with sodium copper chlorophyll concentration increased, the dyeing rate is not always increased but increased at first and

decreased again in the peak. When the mass concentration of 1 g /L, dyeing rate reached its peak.[11]

Epilogue

Linen fabric heat quickly, wearing a cool , solid wear, but the poor performance of its coloring , there are many difficulties in the dyeing process of flax fibers . In order to improve the dyeing properties of flax fibers , we can use urea, expansive for flax pretreatmentwe,can also be dyed in rare earth, alkaline and ultrasonic environment,we can also use the new sodium copper chlorophyll dye dyed flax these methods can effectively improve the dye uptake flax fiber.

Keywords：topsoil; heavy metal; pollution

Abstract: There are significant regional differences of the heavy metals contents in urban soils in China. The heavy metals contents in urban soils of the eastern, central and western regions are quite different, and the pollution of capital cities and prefecture -level cities are different. The study about spatial variability, time differences, pollution levels and environmental risks of heavy metals from China's urban soil show that the heavy metal contents in Chinese cities are over the soil background value in China, especially the contents of Cd and Pb , which were 91.37 times and 41.91 times to the Chinese soil background value. And the content of Ni l is only 1.59 times to the Chinese soil background value.There are also obvious differences among different functional areas the city. Meanwhile, the metal content of urban soils change with the length of time of urban development. Nemero comprehensive pollution index of China's urban soil heavy metal was 45.404, which is heavily polluted. The potential ecological risk index of China's urban soil heavy metal is 71.56, which is high potential ecological risk. Different levels of urban pollution with development degrees cause the different environmental risks.

0 Introduction

At present, urban soil heavy metal is still hot topics in the study of environmental science, urban soil is the main medium of heavy metals. As a result, the soil heavy metal research to find out the relationship between human activity and city environment which is of great significance, many scholars studies have found that the city of soil heavy metal has two sources of natural and human activity, especially the accumulation of human activities on the urban soil heavy metal has great influence. Emissions from human activity of various substances in the form of atmospheric particles gas exists in the urban environment, causing the urban environmental problems, these substances into the urban soil in the form of atmospheric dust and so on, which pose a threat to human health through different channels[1].

China is a large country, and a huge number of cities is intensive human activities, but different regions have different levels of urban development. At present the study of China's urban soil heavy metal few, this article analysis the different cities in China from different angles of soil spatial distribution characteristics of heavy metals, understand the different geographical and economic development level in different cities of China the characteristics of spatial distribution and the pollution of heavy metals in soil, thought the city social and economic development.

1. Materials and methods

Urban soil sampling and experimental materials and methods are shown in table 1, the depth of the urban soil sampling of 0 ~ 20 cm 0 ~ 10 cm. Urban soil sampling points the main layout in different functional areas of the city, such as parks, green residential areas such as roads, using mixed four points from 1 to 1.5 kg of samples, indoor after drying, sieving, grinding process such as standby experimental samples. Sample digestion method is HNO3-HCl-HClO4, HNO3 -H2SO4-H2O2, HF-HClO4-HNO3 and mixed acid digestion. Finally, digestion samples by atomic absorption method, atomic fluorescence method, X-ray fluorescence spectrometry and different methods such as plasma emission spectrometry determination of Cu, Pb, Zn Ni Hg As Cd Cr content in urban soil samples values, these methods are in accordance with relevant national soil sample treatment method[2].

2. Results and discussion

China's urban soil heavy metal content changes

China's urban elements of Cu,Pb,Zn,Cd,As, Mn, Ni ,Cr, Hg and so on which content in soil change range is13.2~112.14 mg/kg ,12.98~25 380.55 mg/kg,58.80~2386.84 mg/kg, 0.11~130 mg/kg ,3.6~39.8 mg/kg,551.47 ~620.39 mg/kg ,12.3 ~73.5 mg/kg ,29.7 ~590.1mg/kg, 0.06~0.414 mg/kg.The average content of each is40.78 mg/kg 1132.71 mg/kg 306.35 mg/kg 8.86 mg/kg18.48 mg/kg 576.17 mg/kg 35.83 mg/kg 112.81 mg/kg0.21 mg/kg，which are China's soil environmental background value of 1.80, 43.57, 4.13, 88.60, 1.65, 0.99, 1.33, 1.85, 1.33 times.Besides Hg, the rest of the standard deviation of heavy metal elements are larger, that they have larger discrete degree, especially the Pb.

China's urban the spatial variation of soil heavy metal pollution

China's urban soil heavy metal content has obvious space difference, as shown in figure 1，shows that China's urban soil heavy metal Cu and Ni, content of the wast> content of the central>content of the east. The content of Pb, Cd and Hg are the east> the central>the wast, the content of Zn and Cr are the east>the west>the central, the central of As is the central> the eastern > the western. At the same time, the Chinese provincial level city of Cu, Pb, Zn, Ni, Hg and Cr content in soil were higher than prefecture city, and the content of Cd and As is the regional cities above the provincial level.

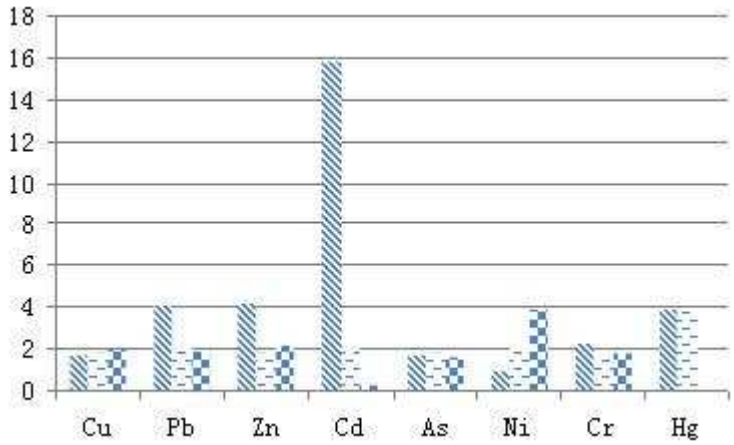

Fig 1. Metal content in different regions

the research on a single city of heavy metals in soil mainly carried out in accordance with the functional partition, city differences in soil heavy metal content in different regions[3]. characters of space distribution of soil heavy metals of guangzhou city, the study found that the soil heavy metal integrated pollution index for the size of the order isold industrial area>traffic area>the new residential area>the new development zone>business zone >the old residential areas>park. Such as Wu yongfeng study of Guiyang city soil heavy metal content differences, different functional areas of potential ecological harm degree of order is industrial park>park>traffic area>suburban farmland>residential area. Such as Yaode qingdao the results showed that the trend of the distribution of all kinds of heavy metal element content is in the southwest and south coastal is higher, central is the second, the east within the scope of the basic background value. Wang zhikun for Luoyang research has shown that the Luoyang city with the approaching of the suburbs to the city of heavy metal pollution, soil heavy mental, the initial pollution→mild contamination→middle level pollution→serious contamination→very high levels of pollution. Kang lingfen the study found that lanzhou city industrial park, the soil polluted by heavy metals is the most serious, followed by the road on both sides and residential areas, and degree of soil contaminated the lightest in the park.

China's urban soil heavy metal time difference

for China's urban soil heavy metal content of the research time is less, in different cities of soil heavy metals were as the city the increase of the formation of a certain land use type time accumulated gradually, and gradually accumulated content. Such as Li Youguo study of soil heavy metal content in nanjing city soil heavy metal with the increase of land use of our time has obvious trend of accumulation, a significant time difference. Gu Dening of Zhengzhou city soil heavy metals such as the study found that zinc content is higher in early urbanization area, the distribution of other elements and the relationship between urbanization history is less obvious. Fu Juanlin study of hangzhou city residential quarters of soil heavy metal content in residential area with the increase of the formation of the residential area time increased significantly.

2.China's urban soil heavy metal pollution assessment and risk analysis

Soil heavy metals in the overall China city, the Nemerow comprehensive pollution index is 45.40, belonging to heavy pollution Pb, zinc, Hg, Cd, Cr, the comprehensive pollution index were 13.98, 22.84, 948.65, 6.88, 4,. 55, belong to high levels of pollution.The most polluted heavy metal elements are Cu, Cd, Ni,As ,which the comprehensive pollution index were 2.35 ,2.55, 2.60, belongs to the moderate pollution, pollution is the lightest of heavy metal elements Cu.

Level every provincial capital cities in China and in the special administrative region, Hong Kong, Guangzhou, Changsha, Shanghai, Hangzhou, Nanjing belong to high levels of pollution of heavy metal pollution, basic is concentrated in the coastal city in the east. Changchun, Guiyang and Xi 'an cities such as the pollution of heavy metal pollution is moderate; Urumqi, shenyang, Hefei, Zhengzhou, Taiyuan and other mid-western cities of heavy metal pollution is light pollution. In the regional city, is located in the east or coastal, such as Xuzhou, Qingdao, Xiangtan, Zhuzhou belongs to high levels of pollution of heavy metal pollution, Baotou, Zhangzhou, Shenzhen belong to moderate pollution of heavy metal pollution, Luoyang and Wenzhou for light pollution. Taicang city for light pollution of heavy metal pollution. China city of Qingdao is the most serious soil heavy metal pollution, inside the comprehensive pollution index was 955.09, mainly due to the Qingdao's Cd pollution is very serious, its value to the Chinese soil Cd element background value of 1340.21 times; Soil heavy metal pollution in cities is the lightest taicang city at county level. Soil heavy metal pollution in cities is the lightest Taicang city at county level[4].

Research shows that China's urban soil heavy metal composite potential ecological risk index was 71.56, potential ecological risk degree is advanced. Including Cu, Pd, As, Hg comprehensive potential ecological risk index were 190.72, 357.33, 43858.45, 144.93, 924.92, and the potential ecological risk degree is advanced. Ni, Cr composite potential ecological risk index were 58.08, 52.12, potential ecological risk degree for the intermediate. Zn composite potential ecological risk index is70.63, potential ecological risk degree is higher. Potential ecological risk was highest heavy metals Cd, the lowest for Cr, In the provincial capital cities and in the special administrative region, Hong Kong, Changsha, Shanghai, Shenyang, Hangzhou, Taiyuan city soil heavy metal potential ecological risk degree is advanced. Guiyang and Hefei have higher degree of soil heavy metal potential ecological risk. Changchun, Guangzhou,Xi 'an and Nanjing city belongs to the intermediate soil heavy metal potential ecological risk degree, Urumqi and Zhengzhou city soil heavy metal potential ecological risk is low. Regional cities, Xiangtan, Zhuzhou, Luoyang, Xuzhou, Qingdao Zhangzhou, Shenzhen city soil heavy metal potential ecological risk degree is high. Baotou city soil heavy metal potential ecological risk is higher, the wenzhou city soil heavy metal potential ecological risk is low. County-level city Taicang city soil heavy metal potential ecological risk of intermediate, the highest potential ecological risks of soil heavy metals in Chinese cities are Qingdao, comprehensive potential ecological risk index is 40222.51,is mainly due to the Qingdao Cd content is higher, and Cd toxicity coefficient is higher.Zhengzhou city soil comprehensive potential ecological risk index is 21.93, the lowest potential ecological risk degree.

3.Conclusion

Soil heavy metal content in Chinese cities exceeds the soil background value, especially the Cd and Pb pollution is serious, the content of China soil background values are 91.37 times and 41.91 times, Ni pollution lighter, its content is 1.59 times of China soil background values. China's urban soil heavy metal content is obvious regional differences, the eastern, central and western regions of urban soil heavy metal content difference is bigger, have different pollution level in the provincial capital cities and regional cities, city also exists obvious difference between different functional areas.

Within the soil heavy metals in Chinese cities, the comprehensive pollution index is 45.40, belong to high levels of pollution.China's urban comprehensive soil heavy metal potential ecological risk index is 71.56, potential ecological risk degree is advanced.Different levels of urban pollution degree is differ, environmental risk is also different.

Keywords: Incorporated Accelerated Corrosion, Nacl, cl^-, Potential

Abstract. Mixing chlorine is one of the ways to ensure the theory and practical steel bars corrosion rate closer when mixing concrete for laboratory electrochemical accelerated corrosion and appropriate chloride dosage should guarantee the steel bars are in the critical corrosion state when we start to accelerated corrosion. By comparing the specimens' experimental compressive strength, chloride-permeation resistance, corrosion potential measured by the half-cell potential method and polarization potential curves measured by the linear polarization potential method with different Nacl dosage, we get the appropriate Nacl dosage is nearly 1.90%, namely cl^- content is about 1.15%.

Introduction

The durability of concrete is insufficient, especially premature failure of concrete structures caused by steel bars corrosion has become a big disaster [1], so it's necessary to study the steel bars corrosion in concrete. Laboratory electrochemical accelerated corrosion is a simple and effective method to get reinforced concrete corrosion specimens [2] and the key point of experiment is to ensure theory and practical steel bars corrosion rate closer so that in actual control current, stipulated time etc. condition we can get needed corrosion specimens, further to ensure the accuracy of experiment. But for electrochemical corrosion, some research has shown that the difference between theory and practical corrosion rate is bigger if we don't mix chlorine in concrete, more than 40% [3], that's because steel bars are passivated at first and have a reaction of electrolysis of water on the surface leading to part of the current loss until OH^- on the surface is reduced enough that can cause the passivation membrane damage and then the steel bars start to corroded if we don't mix chlorine. Therefore in order to ensure the theory and practical steel bars corrosion rate closer we can mix chlorine when mixing concrete. But, for the critical content of cl^- leading to steel bars corrosion, Glass etc. have a conclusion on the critical value, including 0.2%~0.7%,0.4%,1.15%, 0.4%~2.5% etc.[4], not a certain value; and chloride appropriate dosage for incorporated accelerated corrosion should make sure that steel bars are in the critical state of corrosion after 28d's standard curing. So for laboratory electrochemical corrosion, because of uncertain critical content of cl^- and the particularity of appropriate dosage, research on chloride appropriate dosage for incorporated accelerated corrosion has important significance. The content of chlorine and cl^- are a proportion of gelled material in this paper.

Experiment

Materials. (1) Cement: a company in Hebei province, P·I 42.5;(2) Fine aggregate: river sand, fineness modulus of 2.9, medium sand;(3)Coarse aggregate: grading continuously, grade 5 ~ 25;(4) High efficiency water reducing agent: a company in Jiangsu province, JM-II series;(5) Water: tap water;(6) Chloride: Nacl;(7) Steel bars: a company in Zhejiang province, · 16.

Design of Concrete. We need C30 concrete which having sand rate 40% and water cement ratio 51%. By the regulation of water reducing agent to make sure the concrete slump is 180~ 220 mm. Cooperate for finalized per cubic meter of concrete is cement C = 402 kg, water W = 188 kg, sand S = 734 kg, stone G = 1076 kg, water reducing agent A = 1.61 kg. In order to study the appropriate dosage as Nacl plays the role of chlorine, we design 7 kinds of dosage. Specific Nacl content are shown in

Table 1, especially R0 doesn't contain Nacl as a comparison.

Table 1 Different Nacl and cl^- content

No.	Dosage of Nacl（%）	cl^- content（%）
R0	0	0
C1	0.33	0.20
C2	0.66	0.40
C3	1.00	0.61
C4	1.90	1.15
C5	3.30	2.00
C6	5.00	3.04

Test Methods. Nacl is a kind of early strength agent and affects the concrete compressive strength. According to the mechanism that Nacl causes early strength, the cl^- playing the role of early strength agent is fixed in the form of compounds with minerals in cement[5], but steel bars corrosion causing by the damage of passivation membrane needs free cl^-.Therefore, in order to reduce the mixed Nacl's effect on concrete mechanics performance and ensure the exist of free cl^-, we prepare 7 groups of 100mm×100mm×100mm specimens with different Nacl content according to table1 and measure the compressive strength of 3d, 7d, 28d and electric flux of 28d after 28d's standard curing. After that, we provide the basis for determining Nacl appropriate dosage by comparing the results of 6 groups with Nacl with the reference group.

Corrosion of steel bars in concrete is an electrochemical process and electrochemical method is the direction to detection steel rebar corrosion, half-cell potential method and linear polarization potential method are two kinds of widely used methods [6].This article combines two methods to more accurately evaluate the state of steel rebar corrosion. Therefore, we make 6 100mm ×140mm× 280mm specimens with Nacl content of C1 ~ C6 shown in table 1 and place a ·16 in each specimen's central cross-section, which having 20mm protective layer thickness and extending the specimen's ends 15 mm respectively. In order to reduce the humidity effect on corrosion potential, we put the 6 specimens in outdoor for 1d after 28d's standard curing .Through the comparison of experimental steel bars corrosion potential with half-cell potential method and polarization potential with linear polarization potential method that we determine the appropriate cl^- content.

Results and Discussions

Concrete Compressive Strength and Electric Flux. The compressive strength of 3d, 7d and 28d for 7 groups of specimens is shown in figure 1 and 28d's electric flux is shown in figure 2. Figure 1 shows that compressive strength of 3d, 7d for the six groups of specimens with Nacl is higher than the specimen not has Nacl, so Nacl plays a role of early strength agent. Compared with R0 , the compressive strength of 28d for the specimens with dosage of C1 ~ C5 increases by 9.32% , 6.12%, 6.50%, 2.93% and 1.40% respectively ,but the specimen with C6 decreases10.22%, which meaning the dosage is excessive leading to the decrease of strength in case of C6 with 5.00% Nacl. As is shown in figure 2,compared with R0 the electric flux decreases by 15.10%, 11.85% and 15.10% respectively for the specimens with C1 ~ C3, while for the specimens with C4 ~ C6 electric flux increases by 37.37%, 146.93% and 202.21% respectively. That's because when we mix Nacl, in the case of content with C1 ~ C3, the compressive strength of 28d is higher than R0 leading to the increase of close-grained degree, but cl^- is fixed in the form of compounds, so just for the reason of the increase of concrete's resistance to cl^- permeability resulting in a decline in electric flux; while for C4 and C5, the compressive strength of 28d is higher than R0 leading to the increase of concrete's resistance to cl^- permeability, but for the reason of the increase of Nacl resulting in existing free cl^- and leading to the increase of migration cl^- for electrical flux experiment, so the measured electric flux increases ; in the case of content with C6, the excessive Nacl not only makes the concrete compressive strength of 28d fall, which leading to the reduce of concrete's resistance to cl^- permeability, but also causes the increase of free cl^-, so the measured electric flux increases. Considering concrete

compressive strength, C2 ~ C5 changes smaller, and in the case of C4 free cl^- starts to exist, so the Nacl's dosage should be nearly C4, namely the appropriate cl^- content is about 1.15%.

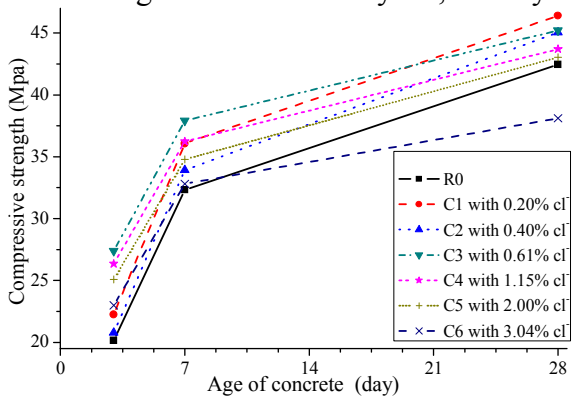

Fig. 1 Concrete compressive strength as the age changes

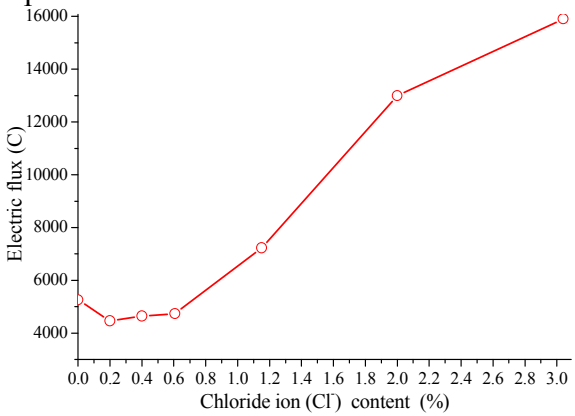

Fig. 2 Concrete coulomb electric flux as the chlorine ion changes

The Detection to Steel bars Corrosion with Half-cell Potential Method. Figure 3 shows how to detect with half-cell potential method and each specimen is divided equally into seven parts along the vertical section so that we can get six test points. The 6 specimens' steel corrosion potential curves after 28d in curing room and 1d in outdoor place is shown in figure 4.If we use half-cell potential method and under the condition of single electrode method, it is considered that the steel bars begin to corrosion when the potential is less than -400mv, but the potential is susceptible to environmental relative humidity, water cement ratio, protective layer thickness, cl^- content etc., so the steel bars corrosion state should be comprehensive evaluation by combining with other test methods [7].As is shown in figure 4, six test points' corrosion potential for the specimens with dosage of C1 ~ C3 are greater than - 400 mv, but from specimen with dosage of C4 six test points' corrosion potential are less than -400mv and specimen with C4 has a mutation compared with specimen with dosage of C3. Although the evaluation method with half-cell potential method is rough but we can still get that steel bars start to corrode from the dosage of C4, so the Nacl's dosage should be nearly 1.90%, namely the appropriate cl^- content is about 1.15% .

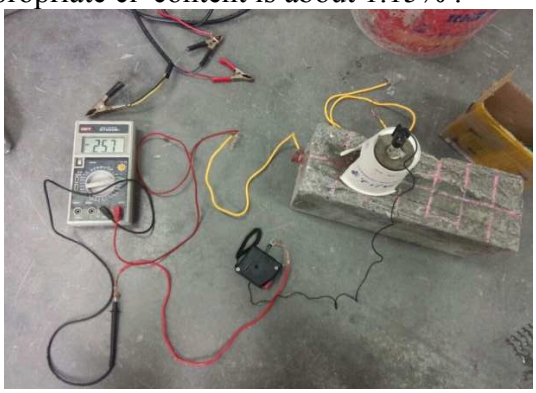

Fig. 3 The detection to steel bars corrosion in concrete with half-cell potential method

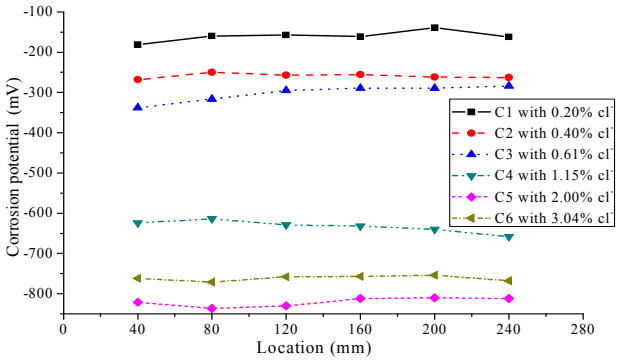

Fig. 4 Steel bars corrosion potential with half-cell potential method

The Detection to Steel bars Corrosion with Linear polarization potential method. Figure 5 shows how to detect with linear polarization potential method and both of the specimens' ends are sealed with epoxyresin. We measure the six different Nacl content specimens' potential within 60 minutes under constant current of 7.03 A, as is shown in figure 6. It can be found that the anode steel potential rapidly rises to the positive direction since power for the specimens with dosage of C1 ~ C3 and the potential value holds steady after 60 minutes' test, meaning the curves are passivated and the steel bars' surface passivation film is in good condition for that specimens. Since the dosage of C4, the anode steel potential rises to positive direction at first and gradually declines within 60 minutes for the specimens with dosage of C4 and C6, suggesting that the steel bars' surface passivation film is partially damaged and the steel bars exist damage; the anode steel potential has been negative at the

first 30 minutes and then holds a stable upright for specimen with dosage of C5, suggesting the steel bars' surface passivation film is damaged seriously than specimen with dosage of C6 and supporting the result that steel corrosion potential with half-cell potential method for specimen with dosage of C5 is minimum in figure 4, possibly caused by the reason that the steel rebar has been partial corrosion before making the specimen with dosage of C5 . Therefore, it can be concluded in the case of the specimen with dosage of C4 that the steel bars passivation film begins to appear partial damage and bars start to corrode with polarization potential method, so the Nacl's dosage should be controlled nearly the situation of C4, namely the appropriate cl^- content is about 1.15% .

Fig. 5 The detection to steel bars corrosion in concrete with linear polarization potential method

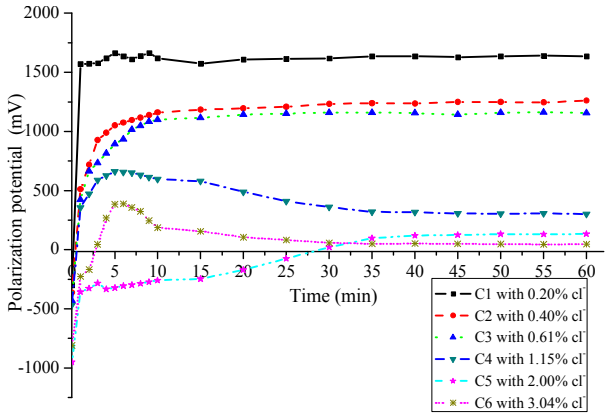

Fig. 6 Steel bars polarization potential with linear polarization potential method

Summary

According to this paper's experimental study, we find that when the mixed chloride is Nacl for incorporated accelerated corrosion, no matter in order to reduce the mixed Nacl's effect on concrete mechanics performance and ensure the exist of free cl^-, or through the comparison of steel corrosion potential with half-cell potential method and steel polarization potential with linear polarization potential method, if incorporated accelerated corrosion experiment depends on this paper's concrete mix proportion and materials , the appropriate Nacl dosage content is nearly 1.90%, namely the cl^- dosage content is about 1.15%, that can ensure the steel bars in concrete are in critical state of corrosion when we start to accelerated corrosion.

Key words: cathode material, co-precipitation method, morphology, electrochemical properties, LiNi0.4Co0.2Mn0.4O2

Abstract. The layered LiNi0.4Co0.2Mn0.4O2was synthesized by co-precipitation method using carbonate sodium as precipitant. The microscopic structural features and morphologies of as-prepared cathode materials were investigated using X-ray diffraction (XRD) and scanning electron microscopy (SEM). And then, the charge-discharge measurements were carried out to determine the electrochemical properties in a voltage range of 2.5-4.6 V. The results show that the pH value in the process of co-precipitation reaction plays a greater part on the electrochemical properties than feed rate does. The cathode materials prepared at higher pH value illustrate better electrochemical properties in the voltage range of 2.5-4.6 V, which can be attributed to a less cation mixing in the cathode material as well as the smaller primary particles and the smaller second particles.

Introduction

Lithium-ion batteries have currently become attractive for portable electronic devices because of their higher output voltage and energy density than other rechargeable systems. Since the introduction of lithium ion batteries in 1990, the layered LiCoO2 cathode has been a popular cathode material because of its ease of production and excellent electrochemical properties, such as high energy density, stable cycling performance and wonderful ratecapability1, 2.However, the relatively high cost and toxicity of cobaltas well asa lure of larger practical cyclic capacity have led to the study of other cathode materials for lithium ion batteries 3 [1-5].

LiNi1-y-zCoyMnzO2cathode materialpossessing the same structure as LiCoO2hasattracted a lot of interest because it combines lower cost with largerpractical cyclic capacity by introduction of Mn and Ni compared to LiCoO24–9. So far, LiNi1-y-zCoyMnzO2cathode materials with different electrochemical performance by adjusting the ratios of Ni, Co and MninLiNi1-y-zCoyMnzO2 have been successfully commercialized. Nevertheless, the new application of lithium ion batteries on the smart phone challenges the present commercialized cathode materials including LiNi1 y zCoyMnzO2 cathode material 10. So, the researches on the enhancement of cyclic capacity of the LiNi1-y-zCoyMnzO2cathode material still draw a great attention11 [6-10]. In general, the increase of Ni content in the LiNi1-y-zCoyMnzO2 is believed as an effective approach to the enhancement of cyclic capacity. However, a high content of Ni in the LiNi1-y-zCoyMnzO2 leads to a deterioration of safety for lithium ion battery and a difficulty for fixing lithium ion batteries in practical application. Therefore, other researches focus on the enhancement of cyclic capacity of the LiNi1-y-zCoyMnzO2 cathode material via raising the upper cut-off voltage which usually result in a poorer cyclic performance12. And, the investigations on doping or coating LiNi1-y-zCoyMnzO2 cathode material were highlighted in recent year since doping or coating was supposed as an significant modification method for many cathode materials and was greatly helpful to the cyclic performance of LiNi1-y-zCoyMnzO2 cathode material even when the upper cut-off voltage is raised to 4.6V. Nevertheless, few work concerns about the effect of the synthesis condition on the electrochemical properties of LiNi1-y-zCoyMnzO2 cathode material when the upper cut-off voltage is raised to 4.6 V [11-14].

In this paper, LiNi0.4Co0.2Mn0.4O2 was chosen as the target cathode material. And then, the effects of feet rate as well as pH value on the physical and electrochemical properties at voltage range of 2.5–4.6 V were investigated in detail.

Experimental

All samples were prepared via a conventional process including co-precipitation and calcinations. The reagent-grade NiSO4·6H2O, CoSO4·7H2O and MnSO4·H2Owere used as starting materials. Firstly, NiSO4·6H2O, CoSO4·7H2O and MnSO4·H2O were dissolved in distilled water in term of formula (Ni0.4Co0.2Mn0.4)CO3. The content of sulfate salt solution was specified as 1 mol L-1. Na2CO3 was used as precipitant and was dissolved into solution of 2 mol L-1. Meanwhile, 1 mol L-1 ammonia solution was used as additive to facilitate the morphologies of (Ni0.4Co0.2Mn0.4)CO3 particles. The sulfate salt solution, Na2CO3 solution and ammonia solution were separately fed into a tank reactor. The ammonia content in the reaction solution was maintained about 0.2 mol L-1 in the process of co-precipitation reaction. The pH values in the reaction solution were adjusted by Na2CO3 solution. And, the temperature of reaction was kept approximately 50 °C. The co-precipitate was aged 2 hours at temperature of 50 °C and then washed using distilled water. And soon afterwards, the co-precipitate was dried at 120 °C over night. The dried co-precipitate was mixed with the excess 5% amount of Li2CO3 in term of Li1.0Ni0.4Co0.2Mn0.4O2. The mixtures were fired in a furnace at 550°C for 5 h and then sintered at 900 °C for an additional 12 h. Finally the samples were cooled directly to room temperature at furnace. The samples prepared at different feed rates of 3 mlmin-1, 5 mlmin-1 and 7 mlmin-1 when the pH value was kept at 9.5 were designated as a, b and c, respectively. Additionally, the samples prepared at different pH values of 9.0, 10.0 and 10.5 when the feed rate was maintained at 7 mlmin-1 were labeled as d, e and f.

The structure for as-synthesized cathode materials were characterized by X-ray diffraction (XRD, D/max 2200/PC, Rigaku, 40kV, 20mA, Cu Kα radiation, λ=1.5406 Å), the size and morphology of the cathode materials were observed with a scanning electron microscope (SEM, Hitachi S-5200).
For the electrochemical measurements, the LiNi0.4Co0.2Mn0.4O2 materials were mixed with 10 wt% carbon black and 10wt% polytetrafluoroethylene binder. This mixture was coated on an aluminum mesh and dried under vacuum at 100°C for 12 h. The cell consisted of a cathode, lithium metal anode and Celgard 2500 separator. The electrolyte was a 1:1 (in volume) mixture of ethylene carbonate (EC) and dimethyl carbonates (DMC) containing 1 M LiPF6. The galvanostatic charge and discharge were controlled between 2.5 and 4.6 V on Arbin BT2000 instrument.

Results and discussion

Table 1 Lattice parameters and ratios of I(003)/I(104) for cathode materials (a, b, c) prepared at different feed rates and for cathode materials (c, d, e, f) prepared at different pH values

Sample	a (Å)	c (Å)	V (Å3)	c/a	I(003)/I(104)
a	2.87627	14.23316	101.97	4.948	0.78
b	2.86459	14.21553	101.02	4.963	0.79
c	2.87627	14.26473	101.91	4.959	0.91
d	2.87049	14.22815	101.53	4.957	0.75
e	2.86821	14.22428	101.34	4.959	1.09
f	2.87051	14.23717	101.59	4.960	1.55

Figure 1 shows XRD patterns for cathode materials (a, b, c) prepared at different feed rates and for cathode materials (c, d, e, f) prepared at different pH values. The positions of peaks in all XRD patterns are almost the same.And, the XRD patterns can be indexed based on α-NaFeO2 structure with R $\bar{3}$ m space group.No impurity phase was detected in all patterns.

In earlier report 13,14, the c/a ratio was used to determine the hexagonallity of a layered material. And it is believed that the material possesses layered characteristics when the c/a ratio is more than 4.899.Moreover, it is generally supposed that the cations ordering of the α-NaFeO2 structure can be indicated from the I(003)/I(104) peak intensity ratio 15,16. So, the lattice parameter values as well as the ratios of I(003)/I(104)are calculated and given in table 1. The lattice constants of a and c for

different sample are slightly different and there is no obvious regularity. Furthermore, the c/a ratios for all samples are very close and more than 4.899, which indicate the as-prepared cathode materials possess layered characteristics. And, there is no obvious regularity, as well. Nevertheless, there are distinct difference among the I(003)/I(104) ratios for different cathode materials. The I(003)/I(104) ratios of cathode materials are lower than 1.2 when the pH value is less than 10.0 in the process of co-precipitation reaction. Moreover, the I(003)/I(104) ratios of cathode materials rise when the pH values increase and the I(003)/I(104) ratio reaches to 1.55 when the pH value is 10.5 in the process of co-precipitation reaction, which indicate that the cations mixing can be alleviated by raising the pH value in the process of co-precipitation reaction. The reason can be attributed to a more homogeneity of transition metal ions in the co-precipitant when the pH value rises in the process of co-precipitation reaction. The complexation of aqueous ammonia is unfavorable to co-precipitation reaction for different transition metal ions though aqueous ammonia is greatly helpful to the formation of spherical particles. The complexation of aqueous ammonia becomes weaker when the pH value rises in the process of co-precipitation reaction. So, a more homogeneity of transition metal ions in the co-precipitant can be achieved when the pH value rises.

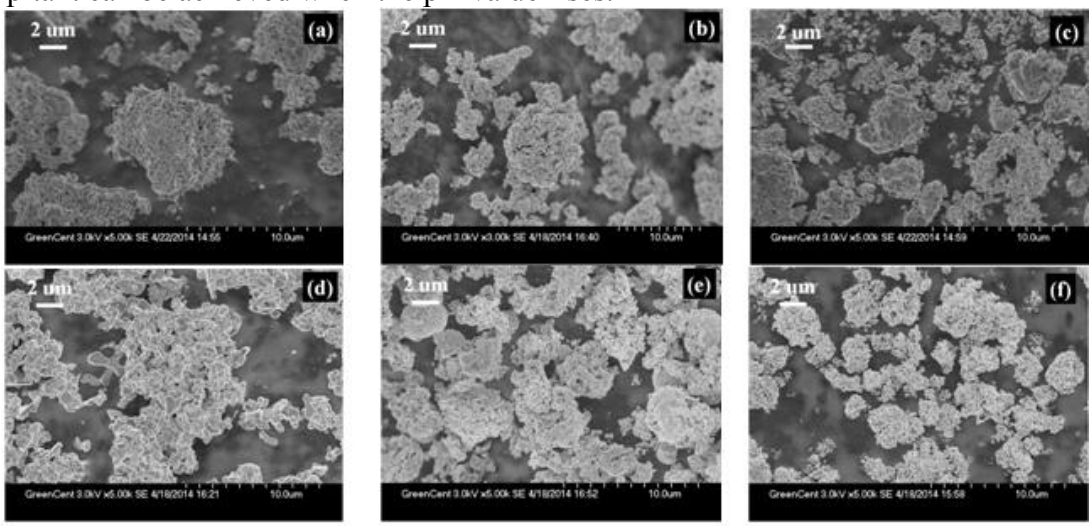

Fig. 2. SEM images for cathode materials(a, b, c) prepared at different feed rates and for cathode materials (c, d, e, f) prepared at different pH values

Figure 2 shows the SEM images for cathode materials(a, b, c) prepared at different feed rates and for cathode materials (c, d, e, f) at different pH values. The morphologies of cathode materials prepared at different feet rates are similar, which indicates that the feet rates of 3 mlmin-1, 5 mlmin-1 and 7 mlmin-1 have few influence on the morphologies of cathode materials. The second particles with a diameter about 5 um are agglomerated from the primary particles with a diameter about 200 nm. Nevertheless, the morphologies of cathode materials prepared at different pH values are thoroughly different though the second particles are still composited of the primary particles. The diameters of the primary particles reduce when the pH value rises in the process of co-precipitation reaction. What is more, the second particles become smaller when the pH value rises. The reason can be explained as follows. In general, the morphologies of cathode materials follow the morphologies of co-precipitates. The co-precipitation reaction include two steps of nucleation and nuclei growth. The nucleation and the nuclei growth are associated with the complexation of aqueous ammonia. The lower pH value is, the stronger complexation is when the aqueous ammonia is specified. A stronger complexation is in favor of the lower nucleation rate and the higher speed of nuclei growth. So, the lowest pH value of 9.0 leads to the biggest primary particles and the relative larger second particles due to a looser agglomeration. Vise verse, the highest pH value of 10.5 results in the smallest primary particles and the relative smaller second particles because of a tighter agglomeration.

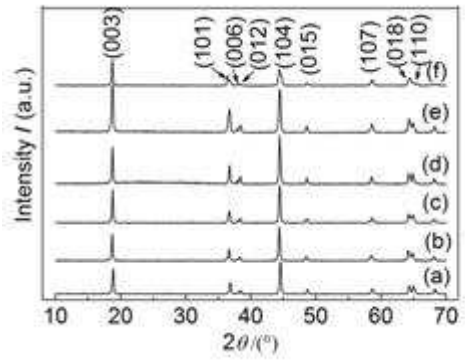

Fig. 1.XRD patterns for cathode materials(a, b, c) prepared at different feed rates and for cathode materials (c, d, e, f) prepared at different pH values

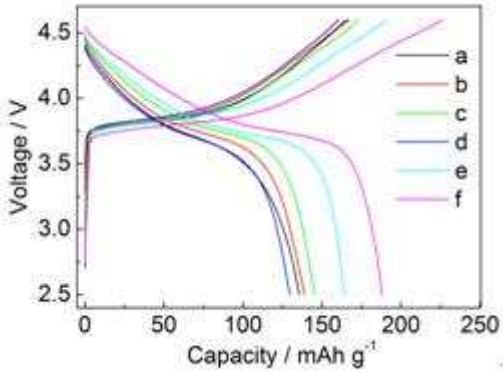

Fig. 3. The initial charge-discharge curves for cathode materials(a, b, c) prepared at different feed rates and for cathode materials (c, d, e, f) prepared at different pH values

Figure 3 shows the initial charge-discharge curves for cathode materials(a, b, c) prepared at different feed rates and for cathode materials (c, d, e, f) prepared at different pH values in the voltage range of 2.5–4.6 V and at 0.1 C. The first discharge capacities for cathode materials prepared at different feed rates of 3, 5 and 7 mlmin-1 are close. The first discharge capacities of sample a, b, c are 135.7 mAh g-1, 139.2 mAh g-1 and 145.5 mAh g-1, respectively.In contrast, the first discharge capacities for cathode materials prepared at different pH values of 9.0, 9.5,10.0, 10.5 are obviously different. The first discharge capacities of sample d, c, e, f are 130.7 mAh g-1, 145.5 mAh g-1, 164.6 mAh g-1 and 188.1 mAh g-1, respectively. Those results are consistent with that the less cation mixing was detected by XRD patterns and the smaller primary was observed in the SEM images when the pH values rise.

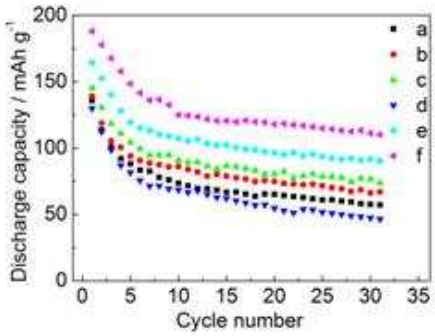

Fig. 4. The cyclic performance for cathode materials(a, b, c) prepared at different feed rates and for cathode materials (c, d, e, f) prepared at different pH values

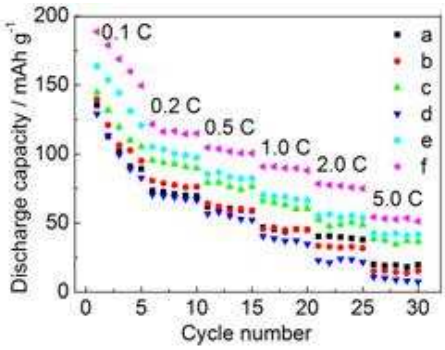

Fig. 5. The rate capabilties for cathode materials(a, b, c) prepared at different feed rates and for cathode materials (c, d, e, f) prepared at different pH values

Figure 4 demonstrates the cyclic performance of 0.1 C for cathode materials (a, b, c) prepared at different feed rates and for cathode materials (c, d, e, f) prepared at different pH values in the voltage range of 2.5–4.6 V. The discharge capacity retentions for sample a, b, c are 42.3%, 48.3% and 50.7%, respectively. And, the discharge capacity retentions for sample d, c, e, fare 36.0%, 50.7%, 54.9% and 58.5%, respectively. It is apparent that the higher pH values in the process of co-precipitation reaction are, the better cyclic performances are for the cathode materials prepared at different pH values.

Fig. 5 shows the rate capabilities for cathode materials(a, b, c) prepared at different feed rates and for cathode materials (c, d, e, f) prepared at different pH values in the voltage range of 2.5–4.6 V. All samples deliver undesirable rate capabilities. The discharge capacity of sample f are 116.2 mAh g-1 at 0.2 C , 101.8 mAh g-1at 0.5 C, 89.5 mAh g-1 at 1.0 C, 76.0 mAh g-1 at 2.0 C and 53.2 mAh g-1 at 5.0 C though it displays the highest discharge capacity of 188.1 mAh g-1 at 0.1 C.

Conclusions

The layered LiNi0.4Co0.2Mn0.4O2 cathode materials have been successfully via co-precipitation method using carbonate sodium as precipitant. The feed rate in the co-precipitation reaction has few influence on the structures, morphologies and electrochemical properties of as-prepared cathode materials when the feed rates altered among 3 mlmin-1, 5 mlmin-1 and 7 mlmin-1. However, pH values in the co-precipitation reaction play a important role on the structures, morphologies and electrochemical properties of as-prepared cathode materials. The less cation mixing was detected in the cathode material prepared at a higher pH value. Moreover, the smaller second particles agglomerated from the smaller primary particles were observed in the cathode material prepared at a higher pH value. So, the cathode materials prepared at higher pH value display better electrochemical properties in the voltage range of 2.5–4.6 V.

Keywords: absorption spectrum, argon ion implantation, strontium titanate

Abstract. The UV-Visible absorption spectroscopy was performed to study the SrTiO3 (STO) single crystals implanted with the fluences of 1.5×10^{15} and 1.875×10^{16} Ar^+/cm^2. The two absorption peaks at 425 and 742 nm were recorded for the low-fluence implanted samples, while the additional peak at 520 nm was measured only for the high-fluence implanted samples. Through the evolution of the absorption peak with the annealing temperature, the 425, 520, and 742 nm peaks are attributed to the isolated oxygen vacancies, oxygen bivacancies, and oxygen interstitials, respectively. The thermal evolution of absorption spectra reveals that the STO lattice defects have poor thermal stability and disappear completely after 400°C annealing treatment.

Introduction

Safe and effective management of radioactive wastes concerns human health and environmental safety and has become an important research subject. The solidification of radioactive wastes is recognized as the most reasonable approach. Currently, the main solidification approaches for radioactive wastes are cement solidification, asphalt solidification, plastic solidification, glass curing, and artificial rock curing. The artificial rock curing is regarded widely as the second generation of solidification body [1, 2]. Strontium titanate possesses the good thermal conductivity, high density, and strong irradiation stability and has very promising prospect for the application of solidifying radioactive wastes [3, 4]. Strontium titanate material will suffer from high-energy particle irradiation during service. Lattice defects lead to the significant degradation of intrinsic performance. Therefore, an understanding of the microstructure, formation mechanism, and evolution of lattice defects is necessary for predicting the reliability and safety of strontium titanate solidification body. There have been various methods to study lattice defects, such as rutherford back scattering/channel analysis, transmission electron microscopy and positron annihilation spectroscopy [5, 6]. Now, we will use the optical absorption spectroscopy to research the strontium titanate lattice defects.

Experiment

The samples are bulk $5\times5\times0.5$ mm^3 STO single crystals and were implanted by 30keV argon ions with the fluences of 1.5×10^{15} and 1.875×10^{16} Ar^+/cm^2. The implantation temperature is room temperature. After the argon ion implantation treatment, the samples were annealed isochronally up to the temperature of 200, 250, 300, 350, and 400 ºC for 30 min. A UV3101-PC UV-VIS-NIR spectrophotometer was used to invesgated the implantation defects.

Results and Discussion

Fig. 1 shows the STO crystals before and after ion implantation. It can be seen that the virgin sample is colorless and transparent. This is because that the STO single crystal has a band gap of 3.3 eV and does not absorb the visible light. After ion implantation treatment, the generation of the lattice defects

results in the striking change. The sample impanted with the fluence of 1.5×10^{15} Ar^{+}/cm^{2} becomes pale blue colour. The sample implanted with the fluence of 1.875×10^{16} Ar^{+}/cm^{2} presents dark blue colour. The change in sample colour stems essentially from the implantation-induced defects which can be measured by optical absorption spectroscopy.

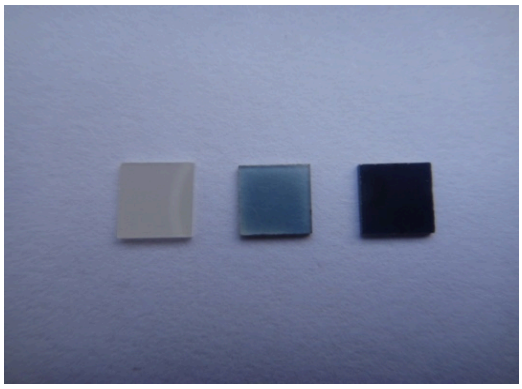

Fig. 1 The photograph of the STO samples implanted with different fluences. virgin (left), 1.5×10^{15} (middle) , and 1.875×10^{16} (right)

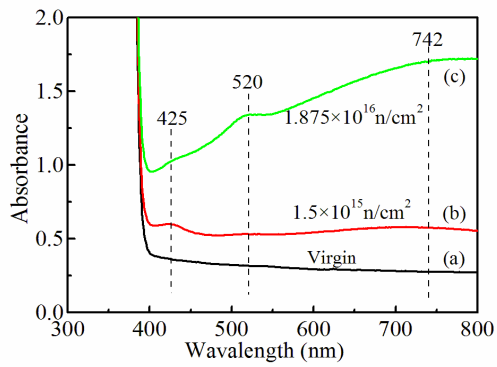

Fig. 2 The optical absorption spectra of the STO samples implanted with different fluences. virgin (a), 1.5×10^{15} (b) , and 1.875×10^{16} (c)

Fig. 2 shows the absorption spectra of the samples implanted with different fluences. As can be seen from Fig. 2(a), the spectrum of the vrigin STO sample presents no absorption peak in the visible light region and has a good visible light transmittance. In addition, less than 375 nm wavelength in the region has The strong light absorption in the region less than 375 nm originates form the electron transition from the top of valence band to the bottom of conduction band, namely the intrinsic absorption band. During the implantation process, the interaction of argon ions with STO lattice atoms leads to the production of a large number of lattice defects. Some defects can introduce the intermediate level between the conduction band and valence band. These new defect levels can be revealed by the absorption spectrum, as shown in figure 2(b) and 2(c). Figure 2(b) show the absorption spectrum of the sample impanted with the fluence of 1.5×10^{15} Ar^{+}/cm^{2}. Tt can be seen obviously changes have taken place in absorption spectra. In addition to the obvious increase of absorption intensity in entire visible light region, the most obvious change is the presence of the two absorption peaks at 425 and 742 nm. When the implantation fluence increases to 1.875×10^{16} Ar^{+}/cm^{2}, as shown in fig. 2(c), the absorption intensities of 425 and 742 nm peaks increase obviously because the the increase of defect concentrations with increase of implantation fluence. It is worth noting that there is 520 nm absorption peak which is absent in low fluence implanted sample and can only appear in high fluence implanted sample. This result demonstrates that the defects corresponding to 520nm peak is not produced directly by ion implantation but can be produced by the gradual defect accumulatation. Hence, the 520 nm peak is likely to come from complex defects. The previous finding shows that the 742 nm peak has nothing to do with impurity and originates from the crystal defects [8]. There exists disagreement with respect to the origination of 425 nm peak. C. Lee supports

that the 425 nm peak comes from iron or nickel impurity defects [9]. K.W. Blazey supports that the 425 nm peak originates froms the complex defects which consist of transition element and oxygen vacancy [8,10]. C.M. Liu discovers that the peak is related to nitrogen impurities [11]. D. Kan and T. Sun believe that oxygen vacancies can introduce shallow acceptor level near the top of valence band the [12,13]. Therefore, the 425 and 520 nm peaks are related to oxygen vacancies and should originate from the electron transitions from acceptor level of oxygen vacancies to conduction band.

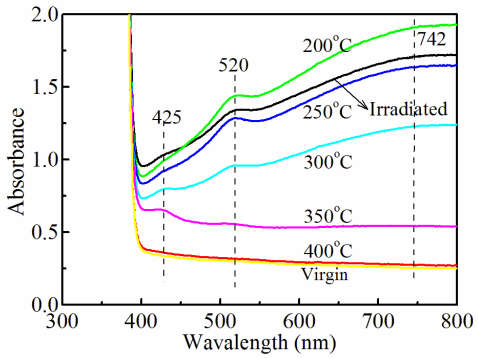

Fig. 3 The absorption spectra of the STO sample implanted with the fluence of 1.875×10^{16} after the annealing treatment with the temperature of 200-400 ºC

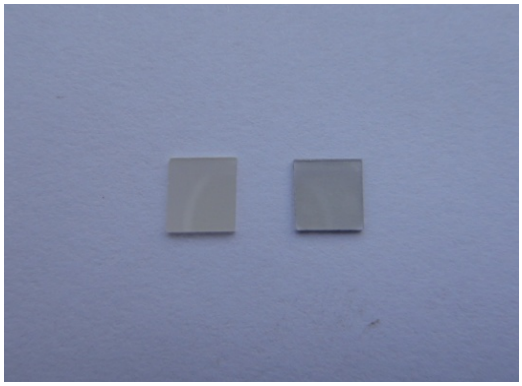

Fig. 4 The photographs of virgin STO sample (left) and the STO sample post-implantation annealed up to the temperature of 400 ºC (right).

In order to determine the assignation of the three absorption peaks, the subsequent annealing treatment was carried out for the STO sample implanted with the fluence of 1.875×10^{16} Ar^{+}/cm^{2}. The post-annealing measured absorption spectra are presented in Fig. 3. After 200 ºC annealing treatment, the intensity of 425 nm peak absorption peak decreases, however the intensity of 520 nm absorption peak increases. Namely, the absorption peak intensity of the 425 and 520 nm peaks have an opposite tendency. This implies that the 425 nm peak corresponding defects can migrate and aggregate into 520 nm peak corresponding defects. The used STO samples are undoped single crystals and donot contain impurities such as iron, nickel, and nitrogen. Therefore the 425 and 520 nm should come from crystal defects. Isolated oxygen vacancy can aggregate into oxygen bivacancy but has a little possibility of aggregation into more complex oxygen clusters. It can be concluded that the 425 nm and 520 nm absorption peaks are very likely originate from isolated oxygen vacancy and oxygen bivacancy, respectively. When the temperature rises to 350 ºC, the 520 nm absorption peak intensity reduced obviously but the 425nm absorption peak intensity is reduced slightly. This is because that oxygen bivacancy can dissociate into isolated oxygen vacancy during annealing treatment. The dissociation of oxygen divacancy into isolated oxygen vacancy partly compensates for the reducation of the intrinsic isolated oxygen vacancy concentration. After the higher annealing temperatures, the 425, 520, and 742 nm absorption peaks are all gradually reduce. when the temperature rises to 400 ºC, the absorption spectrum is similar the spectrum of the vrigin sample. It is noted that the 425 nm and

742 nm absorption peaks disappear at the same time. This shows that 742 nm absorption peak come likely from oxygen interstitials. Fig.4 shows the photographs of the vrigin sample and the sample annealed up to the temperature of 400 ºC. The sample annealed up to the temperature of 400 ºC is very similar to the virgin sample. Both of them appear colorless and transparent. It is demonstrated that the implantation-induced lattice defects has poor thermal stability and can be removed after the annealing treatment up to the temperature of 400 ºC.

Conclusions

We performed UV-Visible absorption spectroscopy to study the implantation defects of STO single crystals. The three absorption peaks at 425, 520, and 742 nm were measured. Through the evolution of the absorption peak with the annealing temperature, they are ascribed respectively to the isolated oxygen vacancies, oxygen bivacancies, and oxygen interstitials. The implatation defects of STO single crystal have poor thermal stability and can removed after the 400°C annealing treatment.

Keywords: microwave irradiation, Au nanoparticles, 3.5 G PAMAM.

Abstract: Using 3.5 G PAMAM as a stabilizing agent, Au nanoparticles have been prepared by reducing $HAuCl_4$ with microwave irradiation. The influence of microwave irradiation at the same ratio of 3.5 G PAMAM to $HAuCl_4$ for the different time and at the different ratio of 3.5 G PAMAM to $HAuCl_4$ for the same time on Au nanoparticles´size and shape has been studied. Au nanoparticles were characterized by UV-vis spectra and TEM. At the same ratio of 3.5 G PAMAM to $HAuCl_4$, the microwave irradiation time has a little influence on the Au nanoparticles´size and shape, meanwhile more dispersed Au nanoparticles were obtained with the appropriate increase of reactive time. At the same irradiation time, bigger and more aggregative Au nanoparticles were acquired as the ratio of 3.5 G PAMAM to $HAuCl_4$ was decreased.

Introduction

Metal nanoparticles have attracted many researchers' attention because of its special stability, electromagnetic properties and optical properties. Especially, gold nanoparticles have aroused great interest in the past decades [1-4]. Methods for preparing nanoparticles include the general chemical method, physical method and comprehensive method. Comprehensive method combines the advantages of chemical and physical preparation of nanoparticles, such as microwave method, laser deposition method. The microwave method is rapid, simple, uniform, and energy saving, but also more uniform nanoparticles can be obtained in the formation of nanoparticles in the reaction.

People have been successfully synthesized Pt, Ag, Pd, Cu and other metal nanoparticles by microwave method, which have small particle size, narrow distribution and good catalytic performance [5-6]. Using 3.5 G PAMAM as a stabilizing agent, Au nanoparticles have been prepared by reducing HAuCl4 with microwave irradiation. The influence of microwave irradiation at the same ratio of 3.5 G PAMAM to HAuCl4 for the different time and at the different ratio of 3.5 G PAMAM to HAuCl4 for the same time on Au nanoparticles´size and shape has been studied.

Organization of the Text

1 The Experimental Part

1.1 Reagents

Ethylenediamine, Methanol: Analysis of pure, Sinopharm Chemical Reagent Co., Ltd; Methacrylate: Chemical pure, Sinopharm Chemical Reagent Co., Ltd; Chloroauric acid: Purity of more than 96%, Shanghai No.3 Reagent Factory; redistilled water.

1.2 The synthesis of 4.5 G PAMAM dendrimer

Methyl acrylate reacted first in methanol by Michael addition reaction with ethylenediamine as core according to the method of Literature[7]. PAMAM dendrimers (generations) were obtained with amine terminated by Ester aminolysis reaction of the product (half generation) by vacuum distillation purification and large excess of ethylenediamine. Methyl acrylate reacted in methanol by Michael addition reaction with the product (generation) by vacuum distillation and purification, 3.5 G

PAMAM dendrimers are prepared by repeating the above process. Its molecular structure is shown in figure 1. The products were identified by IR, characterization of 1H NMR and elemental analysis, the results are consistent with the literature.

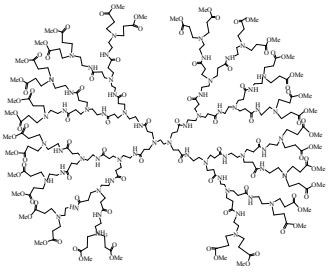

Fig 1 3.5 G PAMAM molecular structure

1.3 Synthesis of the colloidal gold

After 5 min of the ultrasonic oscillation of the mixed solution of 20 mL in the conical flask with a 100 mL 0.88 mL 3.5 G PAMAM aqueous solution (5.54 mmol/L), 8.62 mL water, 10 mL of anhydrous ethanol and 0.5 mL $HAuCl_4$ aqueous solution (9.706 mmol/L) (n (3.5G PAMAM): n ($HAuCl_4$) =1:1), 700 W output power of microwave irradiation were 10 s, 20 s, 30 s, 40 s, 50 s at 2450 MHz after microwave modification and electric stirring. The color of the solution quickly changed from light yellow to purple red at the microwave irradiation; After irradiation and being removed the conical flask, the solution were continued stirring for 30 min to prepare stable gold nanoparticles at room temperature. The colloidal gold that the 3.5 G PAMAM and $HAuCl_4$ molar ratio was 1 were prepared for the different time 10 s, 20 s, 30 s, 40 s, 50 s .The same method can be used for proper exposure time of 30 s, the colloidal gold were prepared at the different ratio of 3.5 G PAMAM to $HAuCl_4$ 3.5 G PAMAM and $HAuCl_4$ molar ratio of 5, 2, 1, 1/2, 1/5. the colloidal gold is stable because the color has not changed and there is no precipitate after being stored at room temperature for several months.

1.4 Sample characterization

Using TU-1810SPC made by Beijing Purkinje General Instrument Co., Ltd. ultraviolet visible (UV-Vis) absorption spectrum analyzer test specimens of UV-vis; The Hitachi H-600 transmission electron microscope (TEM) morphology of the specimens were observed, a voltage of 100 kV, the metal sol drops in the previously covered Formvar film copper net, natural drying electron microscope specimen; RIGAKU DMAX-3C Rigaku X - ray diffraction, a voltage of 30 KV, current of 25 mV, the metal sol at 40 ℃ vacuum rotary evaporation into thick sol, then vacuum drying to get solid samples.

2 Results and Discussions

2.1 Absorption spectra of UV-Vis

Figure 2 is uv-vis spectra after microwave irradiation with different time at the same ratio of n（3.5 G PAMAM）：n（$HAuCl_4$）= 1. As can be seen from the diagram, the absorption peak of 3.5 G PAMAM dendrimers are 288.5 nm and 228 nm; The absorption peak around 530 nm is the surface plasmon resonance absorption peak of gold nanoparticles; Gold nanoparticles' size and shape have effect of the surface plasmon resonance absorption peak position; on the contrary, surface plasma resonance absorption peak position also reflects the gold nanoparticles in the size and shape. The surface plasma resonance absorption peak which change red shift increases from 520 nm to 530 nm when the irradiation time increased from 10 s to 20 s. The resonance absorption peak position has a little mobile as the exposure time has been extended. The further increase of the irradiation time don't lead to obviously change in surface plasmon resonance absorption peak of gold nanoparticles.

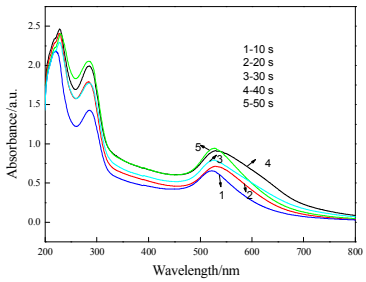

Fig 2 UV-vis spectra of Au nanoparticles prepared by microwave irradiation at the different time

Figure 3 is uv-vis spectra of gold nanoparticles at the different ratio of 3.5 G PAMAM to $HAuCl_4$ for the same time of 50 s. As can be seen from the diagram, surface plasmon resonance absorption peak position increases gradually from the beginning of the 517 nm to 552 nm, the resonance absorption peak change red shift and gradually widen. Which shows that, Au nanoparticles' size become larger and have a tendency to cluster.

（$K=n_{(3.5\ GPAMAM)}/n_{(HAuCl4)}$）

2.2 TEM Characterization Results

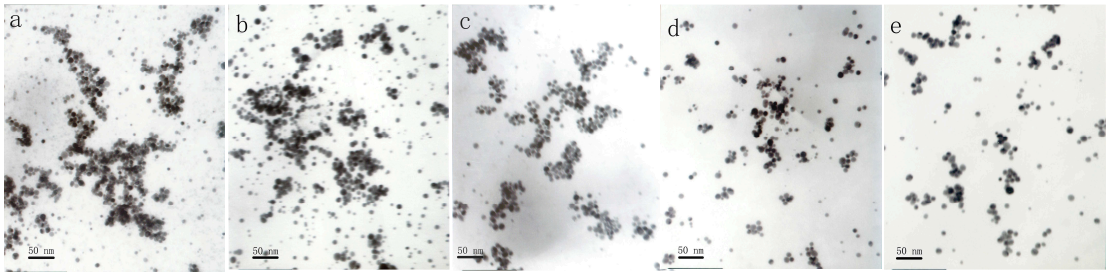

Fig 4 TEM Photographs and particles size distribution histograms of Au nanoparticles prepared by microwave irradiation at the different time
a: t=10 s; b:t=20 s; c:t=30 s; d:t=40 s; e:t=50 s

Figure 4 is TEM picture of gold nanoparticles prepared by using microwave irradiation for the different time at the same ratio of n（3.5 G PAMAM）：n（$HAuCl_4$）= 1. As can be seen from the diagram, Au nanoparticles´size and shape had no obvious change for the different time, which is consistent with the result of ultraviolet visible spectrum measured above. Furthermore that can be seen from figure 4, gold nanoparticles have better dispersion as irradiation time may be extended appropriately. Gold nanoparticles disperse best when irradiation time was 50 s.

Figure 5 is TEM picture of gold nanoparticles at the different ratio of 3.5 G PAMAM to $HAuCl_4$ for the same time of 50 s. As is showed in figure 5 of a, gold nanoparticles size was the smallest and the most homogeneous distribution. Bigger and more aggregative Au nanoparticles were acquired as the ratio of 4.5 G PAMAM to $HAuCl_4$ was decreased, which is consistent with the result of ultraviolet visible spectrum measured above.

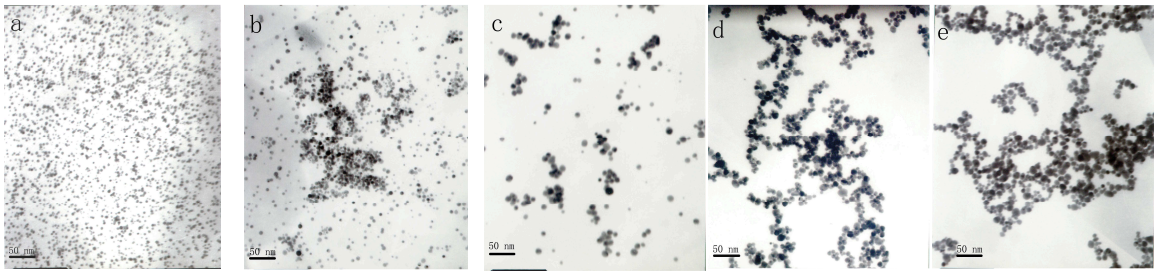

Fig 5 TEM Photographs and particles size distribution histograms of Au nanoparticles prepared by microwave irradiation at the different ratio of reactants for 50s
a:K=5; b :K=2; c:K=1; d:K=1/2; e:K=1/5
（$K=n_{(3.5\ GPAMAM)}/n_{(HAuCl4)}$）

Summary

Using 3.5 G PAMAM as a stabilizing agent, Au nanoparticles have been prepared by reducing $HAuCl_4$ with microwave irradiation. At the same ratio of 3.5 G PAMAM to $HAuCl_4$, the microwave irradiation time has a little influence on the Au nanoparticles´size and shape. At the same irradiation time, bigger and more aggregative Au nanoparticles were acquired as the ratio of 3.5 G PAMAM to $HAuCl_4$ was decreased. In short, at the same irradiation time of 50 s and at ratio of 3.5 G PAMAM to $HAuCl_4$ of 5, the smallest nanoparticles has been obtained and distribution is the most uniform.

Keywords: Thermal physical simulation, high-carbon steel, controlled cooling, phase transformation of pearlite

Abstract. In this paper, critical temperature of phase transformation and continuous cooling transformation (CCT) curve of S87B were determined by hot uniaxial compression tests. At several of cooling speed, the microstructures were studied. The results indicate that the critical temperature of phase transformation become lower with cooling speed increasing, the min interlamellar spacing of pearlite was 0.125μm when the cooling speed was 4℃/s, the best cooling speed of phase transformation area was during (3-4)℃/s..

Introduction

With the span of large span cable-stayed bridge and suspension bridge becoming more and more widely, the higher workable performance of bridge cable was put forward. The bridge over akashi channel in Japan used 1770 MPa grade of φ5 mm galvanized steel wire [1], Sutong bridge (1088 m) first adopted 1770 Mpa grade of 7 mm galvanized steel wire [2]. With the span of bridge increase to 2000 m or more, such as the mainspan of the Italian messina bridge reach 3300 m. So it is necessary to develop the galvanized steel wire for bridge cable of 1860 Mpa and higher strength level.

Through appropriate sorbite and alloying technology to improve the tensile strength of wire rod is basis of getting high strength galvanizing steel wire for bridge cable [3-5]. High tensile strength and well plasticity index of hot rolled wire were accepted by reasonable technology of controlling cool process. In this paper, critical temperature of phase transformation and continuous cooling transformation (CCT) curve of S87B were determined by hot uniaxial compression tests, which provided the basis for the establishment of controlled cooling process.

Determination of the critical point of phase transition temperature

S87B CCT curve and its application

S87B structure depends not only on component, but also closely related to Controlled rolling and Control cooling [6-7]. If Controlled rolling and controlled cooling parameters is unsuitable, may appear fragile tissue like martensite or bainite, not conducive to deep processing. So, we should make reasonable controlled rolling and controlled cooling process. The best method for determining CCT curve is basic experimental methods.

Experimental samples and method. Laboratory sample is cylindrical specimens, specifications for Φ6×15mm, Chemical composition, see Table 1. The experimental program is developed, see Fig.4. The experimental steel sample is heated to 1050℃ at 10℃/s velocity, heating 5 minutes, and then cooled to 900℃. The experiment has simulated the deformation process of finish rolling. Deformation is 35%, the rate of deformation is 20s-1,then cooled to 860℃,last cooled to room temperature continuously at different cooling rates(1, 3, 4, 5, 15℃/s).

Experimental results and analysis. Under different cooling rate metallography and phase transformation point of S87B is as shown in Fig.5 and Table 3. CCT curve of S87B see Fig.6.

when cooling rate is 5℃/s, metallurgical structure started a small amount of martensite, the content of pearlite and lamellar spacing became narrowing, with the cooling speed increasing. when cooling speed is 15℃/s, the content of the martensite is 50%. The interlamellar Spacing, pellet size of Pearlite and the strength, toughness of steel are closely related; the smaller of the interlamellar Spacing, pellet size of Pearlite, the higher of the strength, toughness of steel. The main reason is because of ferrite and cementite thin slices, increase of the phase interfaces, Under the action of external force, the Deforming resistance will increase, but Increasing martensite content will greatly reduce the plasticity and toughness of steel, so sorbite which have good plasticity and toughness is the most ideal initiation structure. With the cooling speed increasing, transformation temperature of Pearlite decreasing, Phase transformation zone temperature reached the maximum when the cooling speed is during 3~4℃/s. when Cementite appeared, the temperature is during 645~625℃, the temperature of pearlite transformation is during 580-560℃. So, the best cooling speed of phase transformation area was during three and 4℃ per second.

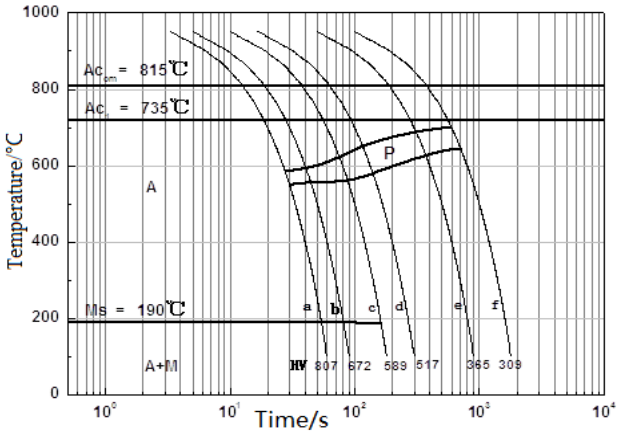

Fig.6 CCT of S87B

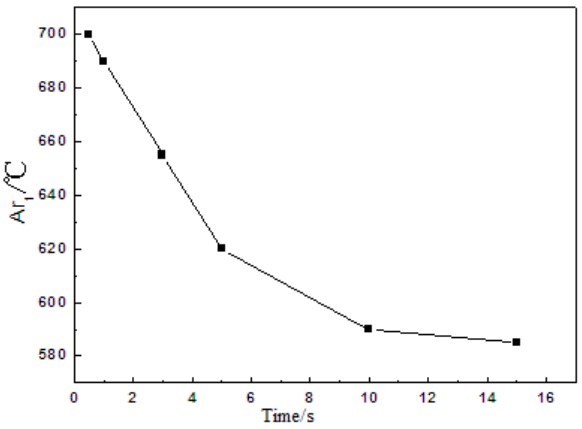

Fig.7.The influence of phase transition temperature of Ar1 on different cooling speed of S87B

Because deformation of wire is done in the pass system, so, in production, Deformation cannot be adjusted widely. Therefore, it is necessary to control the final rolling temperature. In this chapter, it discusses about the influence of cooling velocity on phase transformation and metallurgical structure.

The influence of cooling velocity on Phase transformation rules. During 1 and 5℃/s, temperatures of Ar_1 fell by 60℃. See Fig.7.

The influence of cooling velocity on metallurgical structure. Experimental method. Experimental materials such as shown in Table 1.By scanning electronic microscope, it was observed that metallurgical structure and the pearlite interlamellar spacing at under different cooling speed, then, by Image Tool it was measured that the tissue content and the pearlite interlamellar. The specimen which is using mechanical property test according to experimental scheme of Fig.8 make the Thermal Simulation Experiment of Compress Deformation, then as shown in Fig.9 the Deformation region of the specimen reprocessed into cylinder , measuring their mechanical properties.

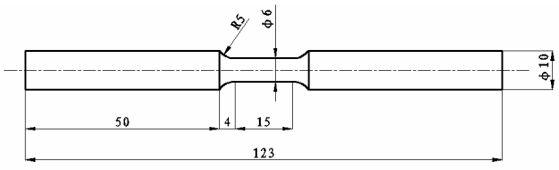

Fig.8 Thermal simulation processing map of the sample

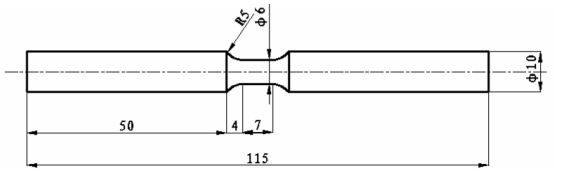

Fig.9 Tensile specimen processing map

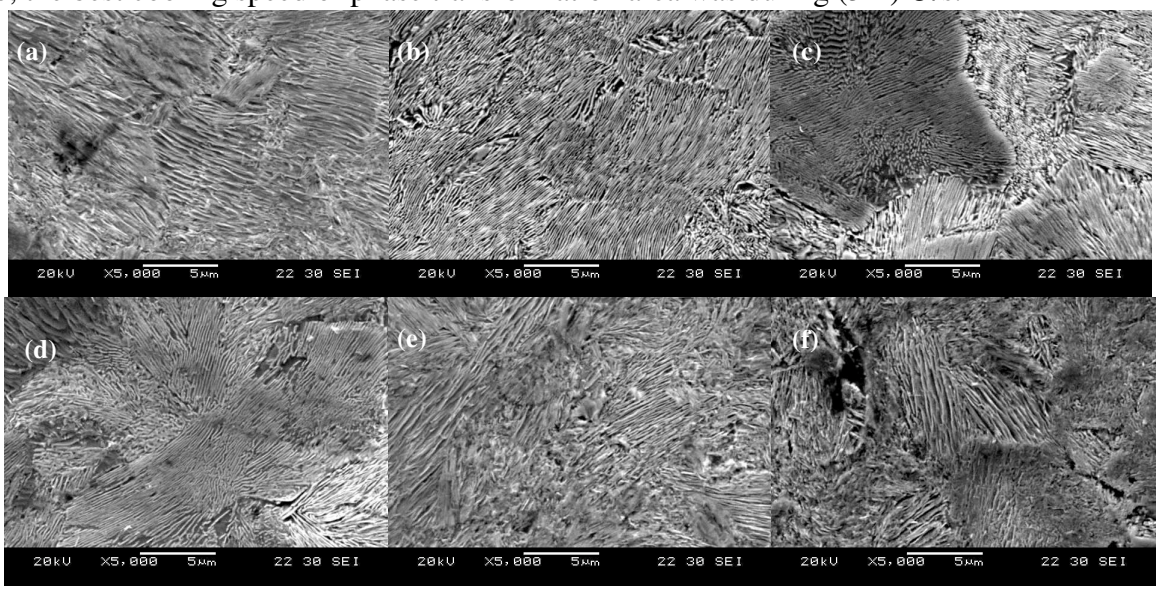
Experimental results and analysis. When the cooling rate was 4℃/s, Cementite, pearlite and sorbite appear, sorbite content increases with the increasing of cooling rate. When the cooling rate of 4℃ /s, sorbite content reached the maximum, about 90%; When the cooling rate of 5℃/s, martensite appear, and sorbite content have shown a sharp decline; When the cooling rate of 15℃/s, sorbite content supplies only a small proportion of structure, martensite is about 50%. Pearlite photos see Fig.10, pearlite interlamella and Mechanical properties see Table 4.

The diameter of pearlitic colony will depend crucially on the original austenite grains, and interlamellar Spacing of Pearlite will depend crucially on formation temperature of Pearlite, It decreases with the decrease of formation temperature of Pearlite [10-11] (or the increase of supercooling degree).When the cooling rate was 4℃/s, grain size and pearlite interlamellar achieved the minimum. When the cooling rate was less than 5℃/s, grain size diminishes with increasing of cooling rate, when the cooling rate was 4℃ /s, the min interlamellar spacing of pearlite was 0.125μm. When the cooling rate of more than 4℃/s, with increasing of cooling rate, martensite content increase sharply, Pearlite nucleation sites reduce, pearlite interlamellar is increasing.

When the pearlite interlamellar spacing decreases, ferrite and cementite becomes thinner, under the action of external force it can slip and produce plastic deformation, and can also be bent, so that the capability of plastic deformation of the steel increased。Reduce the pearlite colony diameter, increasing grain orientation tends of unit volume of pearlite interlamellar , It makes the possibility of stress concentration decreases caused by large amount of plastic deformation occurs in the partial,

thus decreasing the diameter of pearlitic colony and interlamellar Spacing of Pearlite can improve the strength and toughness [10].

So, the best cooling speed of phase transformation area was during (3-4)℃/s.



(a)15℃/s,(b) 10℃/s,(c) 5℃/s,(d) 4℃/s,(e) 3℃/s,(f) 1℃/s

Fig.10. pearlite photos of S87B under different cooling rate

Table4. Grain size and pearlite interlamellar spacing of S87B

Cooling rate /℃·s^{-1}	pearlite interlamellar /μm	Mechanical properties		
		Rm/MPa	A/%	Z/%
1	0.1734	1210	10	36
3	0.1598	1235	12	35
4	0.1250	1250	11	38
5	0.1460			
10	0.1300			

Conclusions

(1) Critical temperature of phase transformation of S87B: Ac_{cm}＝815℃; Ac_1＝735℃; Ar_{cm}＝765℃; Ar_1＝660℃; Ms＝190℃.

(2)When the cooling rate was 4℃/s, metallurgical structure is Fe_3C and P; When the cooling rate was 5℃/s, metallurgical structure is Fe_3C+P+M.

(3)When the cooling rate was 4℃/s, the min interlamellar spacing of pearlite was 0.125μm.

(4)The best cooling speed of phase transformation area was during three and 4℃ per second.

Keywords: Ruthenium, Zinc, Zirconium, Waste zirconium dioxide loaded ruthenium-zinc catalysts, ICP-OES, KOH-KNO_3 fusion

Abstract: A technique for simultaneous determination of Ru, Zn and Zr in waste Ru-Zn/ZrO_2 catalysts using ICP-OES after sample digestion by high temperature fusion with KOH-KNO_3 mixture was described. Such experiment conditions were investigated as the influence of sample digestion methods, fusion time, fusion temperature, the dosage of KOH-KNO_3 mixture and interfering ions on the determination. Under the optimized conditions, the limits of detection (LODs) of Ru, Zn and Zr for tested solutions were 11, 8 and 5 ng mL^{-1}, respectively. The relative standard deviations (RSDs) for Ru, Zn and Zr were 2.01, 2.55 and 1.92 % ($C_{Ru, Zn, Zr}$ = 1 mg L^{-1}, n = 7), respectively. The linear ranges of calibration graphs for Ru, Zn and Zr were 0 ~ 100.00 mg L^{-1}, 0 ~ 50.00 mg L^{-1} and 0~60.00 mg L^{-1}, respectively. The proposed method was applied to determine the practical samples with good recoveries and satisfactory results.

Introduction

In 1989, the Asahi Chemical Industry Co. industrialized the process for producing cyclohexene from the selective hydrogenation of benzene based on Ru-Zn/ZrO_2 catalysts, and a cyclohexene selectivity of 80% as well as a benzene conversion of 40% were obtained, which set off research upsurge of catalysts for hydrogenation of benzene to cyclohexene [1, 2].Every year waste Ru-Zn/ZrO_2 catalysts to come into being were considerable. Quantitative determination of Ru, Zn and Zr in waste Ru-Zn/ZrO_2 catalyst samples not only could calculate the attrition rate of ruthenium in the catalytic reaction, but also had a great significance to recycle Ru, Zn and Zr. Hence, a reliable and efficient analytical technique was required for determining Ru, Zn and Zr in waste catalyst samples.

Several analytical techniques were applied for the determination of ruthenium in various samples, such as neutron activation analysis (NAA) [3, 4], atomic absorption spectrometry (AAS) [5-7] and inductively coupled plasma atomic emission spectrometry (ICP-OES) [8], NAA could hardly be considered a routine approach due to the complexity and cost of the required instrumentation. Atomic absorption spectrometry (AAS) could also be applied for ruthenium determinations in various samples. However, such method suffered from severe matrix effects and simultaneous multielement determination was very difficult. ICP-OES was considered one of the most suitable instrumental techniques for determination of Ru, Zn and Zr in different samples owing to its excellent analytical performance, such as multielement capability, wide linear dynamic range, low detection limit and good precision.

Another crucial step in the analysis of PGEs was sample digestion. It was well known that (metallic) Ru was very resistant to chemical attack [9]. Another problem encountered in Ru analytics was that oxidative conditions during the digestion stage might lead to Ru losses due to formation of volatile RuO_4. For this reason the use of a lower amount of nitric acid compared to the aqua regia composition (3:1 (v/v) HCl–HNO_3) in Ru digestions had been recommended [10]. Digestions in closed vessels with different acid mixtures also had been applied in determinations of low concentrations of Ru and other platinum group elements, e.g. in geological and environmental

materials [11, 12]. In addition, a fusion method with KOH-KNO_3 mixture had been applied for the determination of Ru only in carbon-supported catalysts [13]. As far as we know, there was no report on simultaneous determination of Ru, Zn and Zr in waste Ru-Zn/ZrO_2 catalyst samples by fusion method with KOH-KNO_3 mixture in the literature. Zn and ZrO_2 were very easy to digest by acid or alkali in the high temperature. The aim of this study was to achieve a complete Ru digestion with no losses. The Ru, Zn and Zr contents in the digested samples were determined with the ICP-OES technique. A fusion method with KOH-KNO_3 mixture and a Teflon pressure vessel digestion method were applied for the digestions of Ru, Zn and Zr in waste Ru-Zn/ZrO_2 catalyst materials. The factors affecting experiment conditions were investigated such as the influence of sample digestion methods, fusion time, fusion temperature, the dosage of KOH-KNO_3 mixture and interfering ions on the determination. The practical application of this method to the determination of Ru, Zn and Zr in waste Ru-Zn/ZrO_2 catalyst samples was performed.

Experimental

Instrumentation. A Perkinelmer Optima 7000DV ICP-OES (Perkinelmer, America) was used in this work. The used instrument operating conditions and wavelength were given in Table 1. The instrumental parameters were adjusted according to the manufacturer's recommendations. A muffle furnace WT-221GC (Shanghai Shiyan Electric Furnace, China) was used for sample digestions with the fusion method.

Table 1 ICP-OES operating conditions for determination of Ru, Zn and Zr

Instrument parameter	
Wavelength [nm]	Ru 240.272; Zn 206.200; Zr 343.823
Incident power [kW]	1.4
Cooling gas [L min^{-1}]	15
Auxiliary gas [L min^{-1}]	0.2
Nebulizer gas [L min^{-1}]	0.8
Pump rate [L min^{-1}]	1.5
Nebulizer pressure [kPa]	108

Reagents and Sample Solutions. All reagents used were suprapure grade. Doubly distilled water was used throughout the experiment. Acidic standard 1000mg L^{-1} solutions of ruthenium (III), zinc (II) and zirconium (Ⅳ) (Sigma-Aldrich, Germany) were used. The mixed stock standard solution was prepared by mixing ruthenium (III), zinc (II) and zirconium (Ⅳ) standard solutions, and working standard solutions were obtained by appropriate stepwise dilution of the mixed stock standard solutions. The other reagents were as follows: KNO_3 (Sinopharm), KOH (Sinopharm), HCl (30%, Sinopharm), HNO_3 (65%, Sinopharm).

Digestion by a fusion method. 50-100 mg of the waste catalyst samples were weighed to porcelain crucibles, where the mixture of 1 g KNO_3 and 1g KOH was added to the crucibles and mixed with the samples. The crucibles were covered by lids and inserted into a cold muffle furnace. The furnace was heated to 600 °C and held 1 hour. After cooling down overnight (approximately to 30 °C), the melts were dissolved with 100 mL hot 10% HCl (v/v) solution. To convert Ru to a stable chloro-complex ($RuCl_6^{2-}$), the solutions were transferred into 250ml volumetric flasks and filled to the mark with 10% HCl (v/v) solution. The solutions were diluted and their HCl concentration was adjusted to a minimum of 4% (v/v), depending on the calibration used, prior to the ICP-OES determination. A suitable amount of the reagent blank solution, obtained by fusion, was added to the calibration standards.

Teflon pressure vessel digestion. Waste catalyst samples of 50-100 mg were carefully weighed into the teflon pressure digestion vessel. Digestions were carried out using 6:1 HCl-HNO_3 mixtures for reducing Ru losses due to formation of volatile RuO_4. For the digestions, 20 mL 6:1 HCl-HNO_3 mixtures were added to the digestion vessels. The vessels were closed and the samples were digested in the drying oven with for 6 hour at 180°C. The solutions were carefully allowed to cool to

room temperature prior to opening the vessels. The solutions were heated to dryness and 10 mL of conc. HCl was added. The heating step was repeated three times. After that, the solutions were transferred into 250ml volumetric flasks and filled to the mark with 10% HCl (v/v) solution. The samples were further diluted and their HCl concentration was adjusted to 4% (v/v) prior to the ICP-OES determination.

Results and Discussion

Selection of Digestion Methods. The same waste Ru-Zn/ZrO_2 catalysts sample with Ru, Zn and Zr content of 10.35%, 2.32% and 50.67% was pretreated by the fusion method with KOH-KNO_3 mixture and the teflon pressure vessel digestion method according to the recommended procedure, and then determined by ICP-OES. The results were given in Table 2. As could be seen, the result by the fusion method was in good agreement with the certified values, but the teflon pressure vessel digestion method cause the result of Ru and Zr content on the low side. In waste Ru-Zn/ZrO_2 catalysts sample a part of ruthenium was existed in the form of oxided ruthenium, which was difficult to digest with acid. In additional, $ZrO_2$was not easy to digest with wet method. In this work, fusion method was selected to pretreat samples.

Table 2 Comparison of the two digestion methods

Method	Found [%]
Fusion method	Ru 10.23; Zn 2.25; Zr 50.35
Teflon pressure vessel digestion method	Ru 8.12; Zn 2.26; Zr 20.15

Effect of Fusion Time. Fusion time was an important parameter that influences the digestion of sample. A fusion time in the range of 0.5-2 hour at 600 $^{\circ}$C was investigated. A very short fusion time cannot insure completely dissolution of sample. Therefore, 1 hour was chosen as optimum.

Effect of Fusion Temperature. Fusion temperature was also an important parameter that influences the digestion of sample. A fusion temperature in the range of 400-800 $^{\circ}$C for 1 hour was investigated. A very low fusion temperature cannot insure completely dissolution sample. Therefore, 600 $^{\circ}$C was chosen as optimum

Effect of the dosage of KOH-KNO_3 mixture. 100 mg waste catalyst samples were weighed, the dosage of KOH-KNO_3 mixture (mass ratio 1:1) in the range of 1-4 g was investigated. The result indicated that a very low dosage of KOH-KNO_3 cannot insure completely dissolution sample. Therefore, 2 g KOH-KNO_3 mixture (mass ratio 1:1) was chosen as optimum dosage.

Interferences. The influence of Ca, Mg, Al, Fe, Co, Ni, Bi and Ag, which were the most impurity elements in waste Ru-Zn/ZrO_2 catalyst samples for hydrogenation of benzene to cyclohexene on the determination of Ru, Zn and Zr was investigated. The solutions of 1 mg L^{-1} ruthenium (III), 1 mg L^{-1}zinc (II) and 1 mg L^{-1} zirconium (Ⅳ)containing the corresponding interfering ions were prepared and operated according to the recommended procedure. The results showed that the content of Ca, Mg, Al, Fe, Co, Ni, Bi and Ag up to 5 times more Ru, Zn and Zr had no significant effect on the determination. The content of Ca, Mg, Al, Fe, Co, Ni, Bi and Ag were less than 0.01% in waste Ru-Zn/ZrO_2 catalyst samples by the emission spectrum analysis. In addition, a mass of potassium were brought into the matrix in the fusion process. The influence of potassium on the determination of Ru, Zn and Zr also was investigated. The results showed that the content of potassium up to 120 times more Ru, Zn and Zr had no significant effect on the determination. So the developed method was not affected by the potential interferences from the major matrix elements and potassium.

Analytical Performance. With the use of established experimental parameters as shown in Table 1, the analytical performance of the method was evaluated. The limits of detection were calculated as three times the standard deviation of the reagent blank signal (n=7), in accordance with IUPAC recommendations. The limits of detection (LODs) and the relative standard deviations

(RSDs) of the proposed method were listed in Table 3. Experiment indicated Ru, Zn and Zr concentration within the range of 0 ~ 100.00 mg L^{-1}, 0 ~ 50.00 mg L^{-1} and 0 ~ 60.00 mg L^{-1} had a linear relation with emission intensity, respectively.

Table 3 Limits of detection and precision (RSDs)

Element	Wavelenght [nm]	RSD[a] [%]	Detection limit [ng mL^{-1}]
Ru	240.272	2.01	11.00
Zn	206.200	2.55	8.00
Zr	343.823	1.92	5.00

[a] Ru, Zn and Zr, 1.00 mg L^{-1}, n = 7.

Sample analysis. The practical waste Ru-Zn/ZrO_2 catalyst samples were determined by ICP-OES, with the use of established experimental parameters. Repeat 6 times, the results of found and method recovery were given in Table 4. The recoveries of Ru, Zn and Zr were 93.30% ~ 99.57%, 95.51% ~ 100.51% and 95.41% ~ 99.24%, respectively. The developed method is an ideal kind of method for simultaneous determination Ru, Zn and Zr in waste Ru-Zn/ZrO_2 catalysts.

Table 4 Found results and average recovery

Element	Average Found [%]	Average Recovery [%]
Ru	11.35	97.59
Zn	3.25	102.12
Zr	46.56	96.57

Conclusions

The method with first using KOH-KNO_3 mixture (mass ratio 1:1) as fusion reagents to simultaneously determine Ru, Zn and Zr in waste Ru-Zn/ZrO_2 catalysts for hydrogenation of benzene to cyclohexene by ICP-OES was established, which was simple, quick, high precision. A satisfactory result was obtained when applying it in the practical sample.

Abstract. In this paper, soil-water coupled dynamic analyses are carried out to investigate the influence of stratigraphic composition on the propagation properties of the seismic waves. SYS Cam-clay model is used as the constitutive model which can describe the different state of clayey and sandy soils. Two cases are considered for the composition of ground: one is the sandy ground with diluvial sand, alluvial sand and reclaimed sand; the other one is the clayey layer at the ground surface. It is found that for the sandy ground even though there is certain amplification of the input acceleration wave during the dense sand layer the subsequent seismic waves through the loose sand layers are attenuated significantly due to the occurrence of the liquefaction. While for the clayey ground, even though there is no risk of liquefaction damages at the ground surface the acceleration amplitude is greatly amplified and there is a risk that the structure itself would fail in the strength.

Introduction

Every year there are significant damages caused by the earthquake all over the world, especially the liquefaction damages during the earthquake, which would result in the decrease of bearing capacity, uneven settlement of the ground etc. Many researchers have devoted their efforts to predict the seismic responses of the upper structures [1, 2, 3, 4]. However, those analyses paid attention on the dynamic responses of the structures with given seismic waves observed at the ground surface and there is nearly no glimpse about the propagation of seismic waves from underground engineering bedrock to the ground surface. On the other hand, the forecast of liquefaction is usually considered by an approximate methods based on a microtopography classification in simple, or the FL/PL methods which are explained in Specifications for Highway Bridges [5], but it is proved to be an inaccuracy method by the practical engineering. It is attributed to that neither the influence of the fine fraction content of a liquefiable layer nor the difference in the stratigraphic composition of the depths direction is strictly taken into consideration.

In this paper, a soil-water coupled dynamic finite deformation analysis code called *GEOASIA* [6] is employed to investigate the propagation of seismic waves through the ground taking the stratigraphic into consideration. The research background is introduced in section 1. In section 2, the calculation conditions including the mesh partition, the soil parameters and the input seismic wave are demonstrated. The calculation results are presented in section 3 in detail and the conclusions are shown in section 4.

Calculation Conditions

Mesh Partition. The finite element mesh and the ground composition are shown in Fig. 1. The ground is assumed to be saturated and the plane strain condition is used. The width and the depth of the ground are 76.1m and 30m respectively. There are two kinds of ground type named Case 1 and Case 2. The detailed components of Case 1 are mudstone, diluvial sand, alluvial sand and reclaimed sand from the bottom to the surface, while in Case 2 there are mudstone, diluvial sand and alluvial clay. As for the boundary conditions, the nodes at the bottom are fixed in both horizontal and vertical

directions and the nodes at two side surfaces are only fixed horizontally. The undrained condition is applied at the two side surfaces and the bottom and the atmosphere condition is used at the ground surface. Also, to provide cyclic boundaries as constraint conditions, an equal displacement condition is applied to all components of all nodes at the same height on the two side surfaces [7, 8].

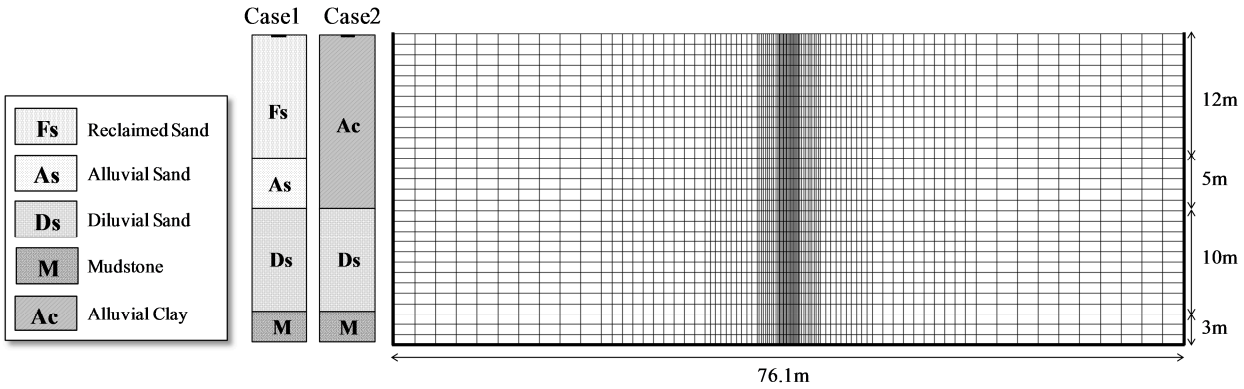

Fig. 1 Finite element mesh and ground compositions

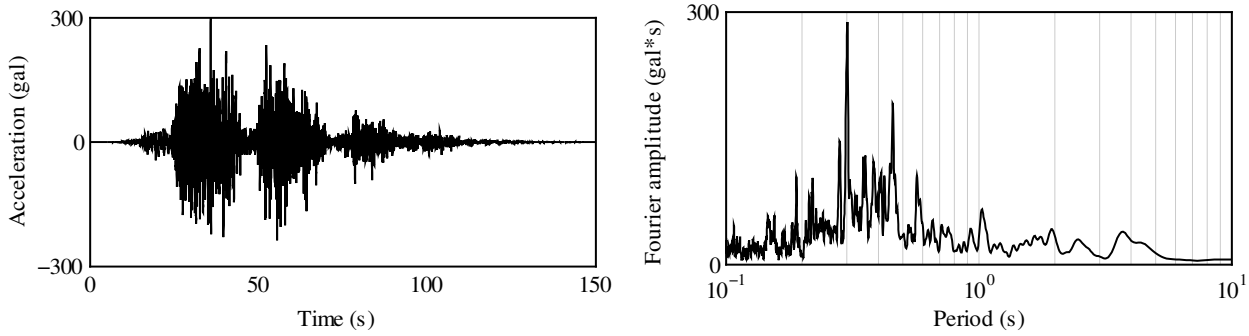
Soil Parameters. The elasto-plastic properties used for analysis are determined by reproducing the mechanical behaviors of the undisturbed specimen sampled from the original ground by the SYS Cam-clay model [9]. A serial of undrained triaxial compression tests and one-dimensional compression tests are carried out on the remolded and undisturbed samples and the numerical calculation based on the constitutive model are also carried out. Through the curve fitting of the experimental and numerical results the soil parameters including elasto-plastic parameters and evolutional parameters can be determined, as shown in Table 1. As can be seen in Table 1, the soil parameters of diluvial sand, alluvial sand and reclaimed sand are exactly same, which is one of the most important contribution of the SYS Cam-clay model, that is only one group of material constant is employed to describe the same soil with different initial states from loose state to dense state.

Table 1 Elasto-plastic parameters and evolutional parameters

	Mudstone	Diluvial sand	Alluvial sand	Reclaimed sand	Alluvial clay
Elasto-plastic parameters					
Critical state index M	0.60	1.10	1.10	1.10	1.60
NCL intercept N	2.10	1.989	1.989	1.989	2.51
Compression index $\tilde{\lambda}$	0.17	0.05	0.05	0.05	0.21
Swelling index $\tilde{\kappa}$	0.003	0.0002	0.0002	0.0002	0.02
Poisson's ratio ν	0.3	0.3	0.3	0.3	0.3
Evolution parameters					
Degradation index of structure a	0.01	5.0	5.0	5.0	0.6
Degradation index of overconsolidation m	10.0	0.12	0.12	0.12	5.0
Rotational hardening index b_r	0.001	3.0	3.0	3.0	0.001
Limitation of rotational hardening m_b	1.0	0.9	0.9	0.9	1.0
Soil density ρ (g/cm^3)	2.707	2.675	2.675	2.675	2.754
Permeability k (cm/s)	1.0×10^{-7}	4.0×10^{-3}	4.0×10^{-3}	4.0×10^{-3}	1.0×10^{-6}

Input Seismic Wave. Fig. 2 shows the acceleration time history and Fourier amplitude spectrum of the input seismic wave in the analysis. This seismic wave is based on the Tokai-Tonankai-Nankai triple segment type earthquake. The maximum acceleration is 300 gal, and the predominant periods are in the range of 0.2 to 0.4s, with a long continuation time of the principal motion, at approximately 100 seconds. The acceleration is input equally in the horizontal direction to all nodes on the bottom

surface of the ground corresponding to engineering bedrock. A viscous boundary [10, 11] is set on the bottom surface corresponding to Vs=570 m/sec.



(a) Acceleration time history (b) Fourier amplitude spectrum

Fig. 2 Acceleration time history and the Fourier amplitude spectrum of the input seismic wave

Calculation Results

The calculation is not just for the duration of the earthquake but will continue after the termination of the seismic motions until the excess pore water pressure dissipates and the consolidation settlement completely converges. During the calculations, the corresponding acceleration waves at two different layers are observed and the Fourier amplitude spectrum analysis is also carried out for the observed acceleration waves. Figs 3-6 illustrate the acceleration response and the Fourier amplitude spectrum at the boundary of two different layers from the bottom to the ground surface in Case 1. In the diluvial sand layer (Fig. 4), the measured acceleration amplifies specially in the long-period wave around 0.3s. On the other hand in the reclaimed and the alluvial sand layers (Figs 5-6), the acceleration is amplified during the early stage of the earthquake, but after the stage of maximum acceleration, the observed acceleration attenuates specially in the short-period wave which is known as the characteristic behavior when the liquefaction takes place. Therefore, the emphasis of the seismic analysis should be put on the liquefaction risk when the surface layer is loose sandy soils, although the amplitude of the acceleration is attenuated due to the liquefaction.

Meanwhile we should note the contradiction in the liquefaction analysis: the liquefaction of the sandy ground would result in the losing of bearing capacity and cause the inclination of structure or uneven settlement of the ground; on the other hand the input seismic wave of the structure at the ground surface would be attenuated significantly due to the possible liquefaction, which, to some extent, would reduce the seismic response of the structure and increase the seismic instability of the structure.

Moreover, in SYS Cam-clay model, the non-linear isotropic Hooke's law is assumed for the elastic deformation of soil skeleton, and the bulk modulus $\tilde{K}$ and shear modulus $\tilde{G}$ are acquired from the following equation:

$$\tilde{K} = \frac{J(1+\mathrm{e}_0)}{\tilde{\kappa}} p' \ , \ \tilde{G} = \frac{3(1-2\nu)}{2(1+\nu)} \tilde{K} \ . \tag{1}$$

where e_0, p' and ν are the initial void ratio, mean effective stress and Poisson's ratio respectively; and $J = (1+\mathrm{e})/(1+\mathrm{e}_0)$, where e is the void ratio at current time. As shown in Eq. 1, since the rigidity of the ground falls with reduction of p', the natural period of the ground increases gradually, and the own natural periods of the reclaimed and alluvial sand layers become dominant at greater than that before the occurrence of the earthquake.

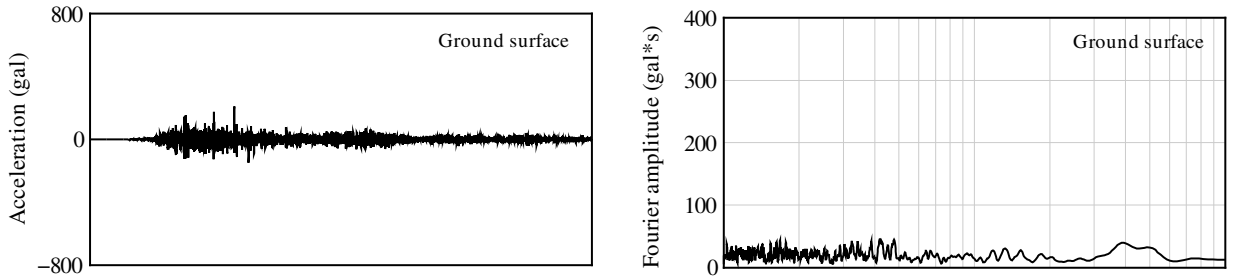
Fig. 5 Acceleration response and the Fourier amplitude spectrum at As and Fs boundary for Case 1



(a) Acceleration time history (b) Fourier amplitude spectrum

Fig. 6 Acceleration response and the Fourier amplitude spectrum at ground surface for Case 1

Figs. 7-9 depict the acceleration response and the Fourier amplitude spectrum at each layer boundary from the bottom to the ground surface in Case 2. For the subsurface clay soil, the decrease in the effective stress is much smaller compared with the subsurface sandy soil in Case 1, as there is no liquefaction in the clayey layer. Therefore, acceleration is greatly amplified in the alluvial clay layer. Paying attention to the Fourier amplitude spectrum, the oscillation at the subsurface layer is predominant at long period component around 0.6 to 1.0s in Fig. 9. From Eq. 1, a smaller shear modulus can be observed in clay, due to a larger swelling index $\tilde{\kappa}$, to clarify the longer period of clayey ground in Case 2.

Comparing Figs 6 and 9, there are significant differences in the acceleration time history and Fourier amplitude spectrum due to the different stratigraphic compositions. Note that in this analysis there are no upper structures. If there are upper structures, the stiffness of the system would changes a lot and the soil-structure interaction should be taken into consideration in order to obtain a precise seismic response.

Fig. 9 Acceleration response and the Fourier amplitude spectrum at ground surface for Case 2

Conclusions

In this paper, soil-water coupled dynamic analyses taking the stratigraphic composition into consideration are carried out to investigate the influence on the propagation of seismic waves and the acceleration waves at the boundary of each two layers with their Fourier amplitude spectrum are measured and demonstrated sequentially. The conclusions are as follows:

(1) When the composition of the ground is sandy soil, although the acceleration waves are amplified significantly in the dense sand layer next there would be considerable attenuation in the amplitude of the acceleration due to the liquefaction in the loose sand layer. Also as the rigidity of the ground reduces due to the liquefaction, the natural period of the ground gradually increases.

(2) When there is a clay layer at the ground surface, the accelerations are amplified significantly in long-period components in the clay layer. Even though there is no risk of liquefaction in the surface

clay layer, the stability of the structure is considerably reduced due to the amplification of the acceleration and the bending strength of the structure itself should be verified specially.

(3) It should be pointed out that the influence of the difference in the stratigraphic composition along the depth is rarely taken into consideration in the conventional seismic analyses. Therefore, it is necessary to consider the influence of stratigraphic composition exactly for the high accuracy liquefaction judgment and seismic responses.

Keywords: Mn-Mg-O_x catalysts, non-thermal plasma, NO,catalytic oxidation

Abstract: The effect of MgO addition on SO_2 tolerance of MnO_x for the NO catalytic oxidation was investigated in this work. MgO addition significantly promotes the SO_2 resistance of MnO_x at low temperature range of 50–250℃. The slight decrease in catalytic activity over Mn-Mg-O_x exposure to SO_2 is attributed to the partially deactivation of the catalytic active site poisoned by SO_2. Through XRD and FT-IR characterization, MgO may effectively inhibit the competitive adsorption between NO_x and SO_2 in manganese site, and enhance SO_2 adsorption on the magnesia surface.

Introduction

At present, selective catalytic reduction (SCR) with NH_3 has been proven to be one of the most efficient methods to elimination of the NO_x [1] . However, this process has several problems[2]. Selective catalytic oxidation (SCO) is an ideal potential technology for simultaneous removal of NO_x and SO_2 from flue gas.

Researches have been reported that some transition metal oxides exhibited high catalytic activity for NO oxidation, Mn/TiO_2 [3], CeO_2-ZrO_2 [4] , $Co/KxTi_2O_5$ [5], are proving to be very effective in the oxidation reaction process. Previous work of our team had proved that MnO_x catalysts have good catalytic activity and wide activity temperature window [2, 6-8]. However, the NO conversion of these catalysts was pronounced deactivation with the presence of SO_2.In this work, the Mn-Mg-O_x catalysts were synthesized by low temperature solid phase reaction method (SP) and modified by the non-thermal plasma, then used for NO catalytic oxidation at low temperature. In particular the effect of SO_2 on the NO conversion was investigated.

Experimental

Catalyst preparation. Mn-Mg-O_x catalysts were prepared by the low temperature solid phase reaction method (SP). Firstly, the manganese acetate, potassium permanganate and magnesium nitrate were mixed and ground fully for 30 minutes. The manganese acetate/ potassium permanganate mole ratio was 2:3, and Mn/Mg was 5:1, 3:1, and 1:1.The mixture was placed in the baking oven at 70℃ for 48 h. The product was filtered and washed with de-ionized water (3~4 times) and absolute ethanol (2~3 times), then dried at 100℃over night. Finally, the catalyst precursor treated by non-thermal plasma (NTP) for 1 h used dielectric barrier discharge (DBD).

Catalytic activity. Catalytic activity measurements for oxidation were performed at 50℃~250℃ in a Pyrex tube fixed-bed flow reactor of 10 mm internal diameter with a gas hourly space velocity of 30000h^{-1} . The reaction gas mixture contained 500ppm NO, 5%O_2, 100ppm SO_2 (when used) diluted in N_2. The sample weight, flow rate were 0.3g, 200mL/min, respectively. The reactions and reactive products of NO, NO_2, SO_2 were measured by Flue Gas Analyzer (KM9106). The NO conversion is defined as $X\,(\%) = (NO_{inlet} - NO_{outlet})/NO_{inlet} \times 100\%$.

Catalytic characterization. X-ray diffraction (D/MAX-2200) patterns were recorded with a Rigaku diffractometer operated at 36 kV and 30 mA by using Ni-filtered Cu Kα radiation (λ=0.15406 nm) at a rate of 5 (°) /min from 2θ=20° to 80°. Fourier transform infrared spectroscopy (FT-IR) of Varian 640-IR was used to determine sulfur-containing species on the catalyst surface. The FT-IR spectra were recorded using the KBr pellet technique on a Thermo spectrometer in the 4400-390cm^{-1} wavenumber range. Before analysis, the sample was ground, and made into pellets with KBr. The analysis temperature was at ambient temperature, and the analyses done ex-situ.

Results and discussion

Catalytic performance of NTP treated catalysts. Fig.1 summarize the results of the catalytic oxidation activities of conventional catalysts compared with catalysts modified by NTP. From Fig.1, the NO conversion of all the plasma treated samples rose by 5%-10%, compared with the conventional catalysts. The results indicated that the NO catalytic oxidation activity of these catalysts treated by NTP were significantly improved.

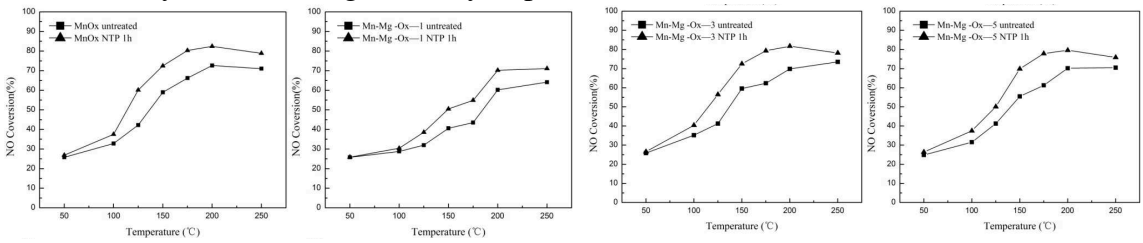

Fig.1. Catalytic performance of NTP treated MnOx and Mn-Mg-Ox-X at 200℃

Catalytic performance of MnO_x compared with Mn-Mg-O_x in the absence of SO_2. Fig.2 shows the catalyst performance for NO oxidation during 50℃~250℃ over MnOx, Mn-Mg-Ox-X, where X represents the molar ratio of Mn to Mg, e.g. Mn-Mg-Ox-(1, 3, 5). In the initial phase, the rate of chemical reactions is increasing with the rise of temperature. Then, NO conversion will decrease at high temperature (250℃),duo to the thermodynamic stability of NO–NO_2,when temperatures above 200℃ the dissociation of NO_2 becomes evident. The NO catalytic oxidation activity was MnO_x≈Mn-Mg-O_x-3>Mn-Mg-O_x-5>Mn-Mg-O_x-1. The NO conversion over the Mn-Mg-Ox-3 was about 82% at 200℃, even at 175℃ and 250℃ it achieved 80% and 79% respectively. However, the catalytic activity of MnOx was close to Mn-Mg-Ox-3.

Effect of SO_2 on MnOx and Mn-Mg-Ox-3. As shown in Table 1, Mn-Mg-Ox-3 catalyst，which treated with N_2 plasma for 60 min, showed high catalytic activity compared with the other samples when SO_2 added. From the above catalytic activity tests showed that MnO_x and Mn-Mg-O_x-3 show a good performence.

Table.1 The NO conversion of over different samples when absence of SO_2 and presence of SO_2.

Sample	NO conversion (absence of SO_2)	NO conversion (presence of SO_2)
Mn-Mg-O_x-1	70.5%	65.4%
Mn-Mg-O_x-3	82%	79%
Mn-Mg-O_x-5	79.7%	70.8%

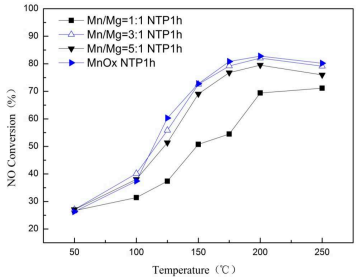

Fig.2 The NO catalytic oxidation activities of MnOx, Mn-Mg-Ox-1, Mn-Mg-Ox-3, Mn-Mg-Ox-5 catalysts

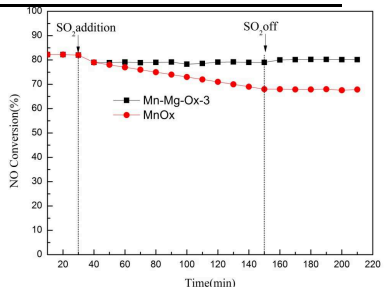

Fig.3. Effect of SO_2 on MnOx and Mn-Mg-Ox-3 at 200℃

In Fig.3, the effect of 100ppm SO_2 addition on the catalytic activity of MnO_x and Mn-Mg-O_x-3 at 200℃ is shown.After the measurement of steady-state conversions in SO_2 absence condition, 100ppm SO_2 was introduced to the reaction gas mixture and NO conversion was measured as a function of time. Over the MnOx catalyst, the NO conversion was gradually reduced with the reaction continuing when 100ppm SO_2 was added into the feed gas mixture. On the other hand, the NO conversion over Mn-Mg-O_x-3 only slightly decreases and was leveling off at 78-79% for a long time. This phenomenon could be explained that a small amount of SO_2 still adsorbed on the Mn-Mg-O_x-3 surface after removing SO_2 from feed gas lead to the activity decreased slightly,but not restored to its previous state. The activity tests results showed that SO_2 has notable negative effect on the MnO_x catalyst, but totally different to the Mn-Mg-O_x-3 catalyst. Also, these results imply that the addition of MgO may be an effective method to avoid the process of sulfation of the MnO_x catalyst surface.

Catalyst characterization. The XRD patterns of the fresh and aged Mn-Mg-Ox-3 (exposed to feed containing 100ppm SO_2) are revealed in Fig.4. For comparison, the XRD patterns of the fresh and aged MnOx are also shown. No magnesium oxides peaks were detected in all samples, mainly due to the low Mg loading. As shown in Fig.4, the peaks of the XRD profile of these are weak, it can be identified most of the weak peaks belong to Mn_3O_4. From the Fig.4 other diffraction peaks of MnO_2 (2θ=12.8°, 18.2°, 28.8°, 37.5°, 49.9°), and Mn_3O_4 (2θ=23.9°, 32.9°, 38.2°) could be observed. Li Hua et al [9], observed that the the catalysts co-existence of MnO_2-Mn_2O_3 might account for the increased oxidation of NO. This was concordant with our experimental result. Furthermore, no new peaks (magnesium- sulfur compounds such as MgS, $MgSO_3$, and $MgSO_4$) ware observed in the spectra of all the aged catalysts.

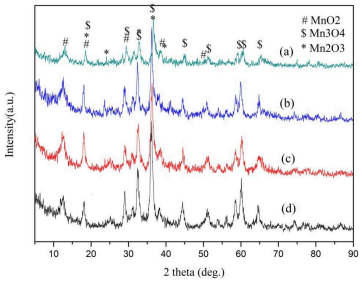

Fig.4. XRD patterns of fresh and aged MnOx and Mn-Mg-Ox-3 exposed to 100 ppm SO_2: (a) aged MnOx, (b) fresh MnOx, (c) aged Mn-Mg-Ox-3, (d) fresh Mn-Mg-Ox-3.

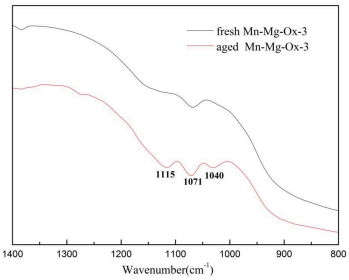

Fig.5. Comparison of FT-IR between fresh and aged Mn-Mg-Ox-3catalyst exposed to 100 ppm SO_2.

Fig.5 exhibits the FT-IR spectra obtained over the fresh and aged Mn-Mg-O_x-3 exposed to 100ppm SO_2. Absorption bands assigned to sulfite species were observed in the aged Mn-Mg-Ox-3. Schneider et al [10], researched infrared absorption properties of SO_2 adsorbed on MgO. The spectrum clearly shows absorption broads in the region 950-1400cm^{-1} are attributed to sulfate and sulfide SO_3^{2-} groups. Wang et al [11], also have found that the band at 1040 cm^{-1} was attributed to the S-O stretching vibration of sulfite-like species produced by the strong chemisorbed SO_2 on the surface reacting with the oxygen lattice of $MgAl_2O_4$, and found that the band at 1395 cm^{-1} and 1070 cm^{-1} were characteristic of the surface sulfate species. Hence, the peaks of 1115 cm^{-1}, 1074 cm^{-1} and 1040cm^{-1} over aged Mn-Mg-Ox-3 could be characterized to the formation of surface sulfur species.

The high stability of the Mn-Mg-O_x-3 catalyst after 2h of reaction on stream in the presence of SO_2 shows that the active sites of catalysts have little effect when addition of SO_2. The phenomenon can be explained that the sulphate or sulphate cannot be adsordates which are stable under reaction condition inhibit further the adsorption of SO_2 or SO_3 from the gas phase [12]. However, NO molecule which significantly smaller compared to SO_2 or SO_3 can be chemisorbed on the unoccupied cations of the catalyst to form active bidentate nitrate species. A similar explanation was also reported by Costa and Efstathiou for the SO_2 stability of Pt/ MgO-CeO_2 during H_2-SCR of NO reaction [13]. The results presented here further show that MgO addition may effectively inhibit the competitive adsorption between NO_x and SO_2.

Conclusions

Mn-Mg-O_x-3 with high resistance to sulphur poisoning for the SCO was demonstrated in this work. Mn-Mg-O_x-3 catalyst presents stability of industrial importance since no stable catalysts in the reaction SCO in the presence of particularly SO_2 have been reported so far. The slight decrease in catalytic activity over Mn-Mg-O_x-3 could be attributed to the partially deactivation of Mn sites poisoned by SO_2. Through XRD and FT-IR characterization, the high SO_2 tolerance of Mn-Mg-O_x-3 at low temperature could be attributed to the effective inhibition of the competitive adsorption between NO_x and SO_2 on catalytic active site and the enhancement of SO_2 adsorption on the magnesia surface with MgO addition.

Abstract. Novel thermoresponsive dendronized monomer bearing azobenzene moiety, 4-(4′-(3, 4, 5-tris (2-(2-methoxyethoxy) ethoxy) benzyloxy) phenylazo) benzyl methacrylate, has been successfully synthesized. The chemical structures of intermediate compounds and dendronized monomer were confirmed by FTIR and ^{1}H NMR. The phase transition behaviors of these intermediate compounds and dendronized monomer were investigated. These intermediate compound and dendronized monomer showed remarkably reversible thermoresponsive phase transition behaviors.

Introduction

Stimuli-responsive polymers, often referred to as "smart or intelligent" polymer systems, which exhibit reversible property changes in response to changes in environmental factors such as temperature, pH or light, have attracted considerable research interest due to their promising potential [1-3]. Recently, thermo- and light-responsive polymers have been reported. Most of these polymers were synthesized by copolymerization of thermo-responsive monomer and light-responsive monomer [4-7]. However, few works have been done on the synthesis of thermo- and light-responsive dendronzied polymer based on dendronized monomer with thermo- and light-responsive moieties.

In this paper, a novel thermoresponsive dendronized monomer bearing azobenzene moiety, 4-(4′-(3, 4, 5-tris (2-(2-methoxyethoxy) ethoxy) benzyloxy) phenylazo) benzyl methacrylate, has been successfully synthesized (Fig. 1). The chemical structures of intermediate compounds and dendronized monomer were confirmed by FTIR and ^{1}H NMR. The phase transition behaviors of these intermediate compounds and dendronized monomer were investigated. The synthesis and characterisation of thermo- and light-responsive dendronized polymer based on the dendronized monomer will be reported in the near future.

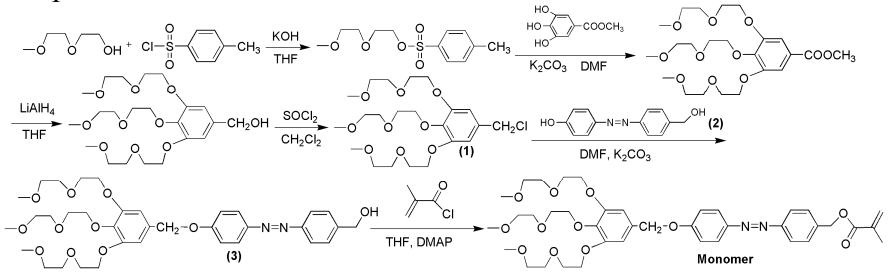

Fig. 1 Synthetic route of the dendronized monomer

Experimental Section

The preparation of the thermoresponsive dendronized monomer bearing azobenzene moiety, 4-(4′-(3, 4, 5-tris (2-(2-methoxyethoxy) ethoxy) benzyloxy) phenylazo) benzyl methacrylate, is described as follows. Firstly, 2-(2-methoxyethoxy) ethyl 4-methylbenzenesulfonate was prepared by esterification of 2-(2-methoxyethoxy) ethanol and *p*-toluenesulfonyl chloride. Secondly, methyl 3, 4,

5-tris (2-(2-methoxyethoxy) ethoxy) benzoate was synthesized by etherification of methyl 3, 4, 5-trihydroxybenzoate with 2-(2-methoxyethoxy) ethyl 4-methylbenzenesulfonate. Thirdly, 3, 4, 5-tris (2-(2-methoxyethoxy) ethoxy) benzyl alcohol was synthesized by reduction of methyl 3, 4, 5-tris (2-(2-methoxyethoxy) ethoxy) benzoate with $LiAlH_4$. Fourthly, 3, 4, 5-tris (2-(2-methoxyethoxy) ethoxy) benzyl chloride was obtained by the chlorination of 3, 4, 5-tris (2-(2-methoxyethoxy) ethoxy) benzyl alcohol with $SOCl_2$. Fifthly, 4-(4′-(3, 4, 5-tris (2-(2-methoxyethoxy) ethoxy) benzyloxy) phenylazo) benzyl alcohol was prepared by the etherification of 3, 4, 5-tris (2-(2-methoxyethoxy) ethoxy) benzyl chloride and 4-((4′-Hydroxy) phenylazo) benzyl alcohol. Finally, the dendronized monomer, 4-(4′-(3, 4, 5-tris (2-(2-methoxyethoxy) ethoxy) benzyloxy) phenylazo) benzyl methacrylate, was obtained by esterification of methacryloyl chloride and 4-(4′-(3, 4, 5-tris (2-(2-methoxyethoxy) ethoxy) benzyloxy) phenylazo) benzyl alcohol. The rude product was purified by column chromatography to obtain the dendronized monomer. The chemical structures of intermediate compounds and dendronized monomer were confirmed by ^{1}H NMR and FTIR.

Results and Discussion

Characterisation of the intermediate compounds and dendronized monomer

The intermediate compounds methyl 3, 4, 5-tris (2-(2-methoxyethoxy) ethoxy) benzoate and 3, 4, 5-tris (2-(2-methoxyethoxy) ethoxy) benzyl alcohol were prepared and characterized in the literature [8]. 3, 4, 5-tris (2-(2-methoxyethoxy) ethoxy) benzyl chloride (**Compound 1**) was obtained by the chlorination of 3, 4, 5-tris (2-(2-methoxyethoxy) ethoxy) benzyl alcohol with $SOCl_2$, colorless liquid, yield: 92%. Fig. 2 shows the ^{1}H NMR spectra of 3, 4, 5-tris (2-(2-methoxyethoxy) ethoxy) benzyl chloride. The chemical shifts are illustrated as follows: ^{1}H NMR (δ, ppm, $CDCl_3$): 6.69-6.64 (m, 2H, Ar-H), 4.50 (s, 2H, -CH_2Cl), 4.29-4.20 (t, 6H, -OCH_2-), 3.89-3.76 (t, 6H, -OCH_2-), 3.76-3.62 (t, 6H, -OCH_2-), 3.62-3.50 (t, 6H, -OCH_2-), 3.45 (s, 9H, -CH_3).

4-((4′-Hydroxy) phenylazo) benzyl alcohol (**Compound 2**) was synthesized by reduction of 4-((4′-Hydroxy) phenylazo) benzoate with $LiAlH_4$, orange solid, yield: 84%. Fig. 3 shows the ^{1}H NMR spectra of 4-((4′-Hydroxy) phenylazo) benzyl alcohol. The chemical shifts are illustrated as follows: ^{1}H NMR (δ, ppm, DMSO): 7.73-7.70 (m, 4H, Ar-H), 7.45-7.43 (m, 2H, Ar-H), 6.78-6.80 (m, 2H, Ar-H), 4.55 (s, 2H, -CH_2O-).

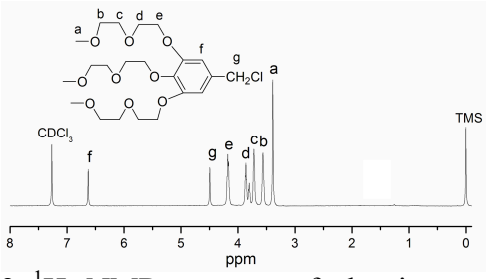

Fig. 2 ^{1}H NMR spectra of the intermediate compound, 3, 4, 5-tris (2-(2-methoxyethoxy) ethoxy) benzyl chloride, in $CDCl_3$-*d*.

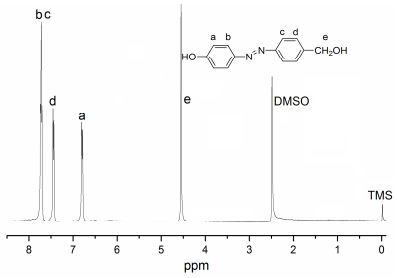

Fig. 3 ^{1}H NMR spectra of the intermediate compound, 3, 4, 5-tris (2-(2-methoxyethoxy) ethoxy) benzyl chloride, in DMSO-*d*.

4-(4′-(3, 4, 5-tris (2-(2-methoxyethoxy) ethoxy) benzyloxy) phenylazo) benzyl alcohol (**Compound 3**) was prepared by the etherification of 3, 4, 5-tris (2-(2-methoxyethoxy) ethoxy) benzyl chloride and 4-((4′-Hydroxy) phenylazo) benzyl alcohol, orange liquid, yield: 88%. In the FTIR spectra Fig. 4a, a strong adsorption band appeared at 3340 cm^{-1}, which is attributed to the -OH stretching vibration. Fig. 4b shows the ^{1}H NMR spectra of 4-(4′-(3, 4, 5-tris (2-(2-methoxyethoxy) ethoxy) benzyloxy) phenylazo) benzyl alcohol. The chemical shifts are illustrated as follows: ^{1}H NMR (δ, ppm, $CDCl_3$): 7.93-7.81 (m, 4H, Ar-H), 7.51-7.49 (m, 2H, Ar-H), 7.08-7.06 (m, 2H, Ar-H), 6.69 (s, 2H, Ar-H), 5.30 (s, 2H, -CH_2O-), 5.03 (s, 2H, -CH_2O-), 4.19-4.18 (t, 6H, -OCH_2-), 3.87-3.81 (t, 6H, -CH_2O-), 3.72-3.67 (t, 6H, -OCH_2-), 3.56-3.54 (t, 6H, -CH_2O-), 3.38-3.36 (s, 9H, -OCH_3), 1.68 (s, 1H, -OH). The peak area ratio of methylene peak g (peak g. Fig. 4b) and methylene peak l (peak l. Fig. 4b) is 1 : 1 and no impure peak is observed, indicating the pure **compound 3** is obtained.

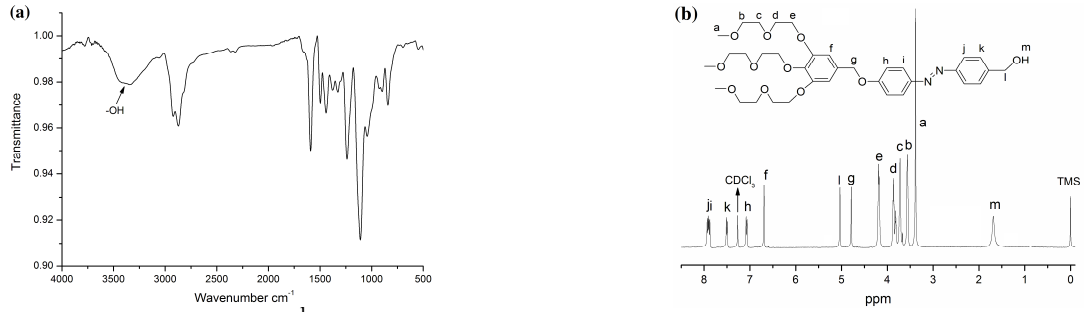

Fig. 4 FTIR spectrum (a) and ^{1}H NMR spectra (b) of the intermediate compound, 4-(4′-(3, 4, 5-tris (2-(2-methoxy ethoxy) ethoxy) benzyloxy) phenylazo) benzyl alcohol.

The dendronized monomer, 4-(4′-(3, 4, 5-tris (2-(2-methoxyethoxy) ethoxy) benzyloxy) phenylazo) benzyl methacrylate, was obtained by esterification of methacryloyl chloride and 4-(4′-(3, 4, 5-tris (2-(2-methoxyethoxy) ethoxy) benzyloxy) phenylazo) benzyl alcohol, orange liquid yield: 85%. In the FTIR spectra Fig. 5a, the –OH stretching vibration band at 3340 cm^{-1} wasn't observed. A strong C=O stretching band appeared at 1718 cm^{-1}, which is attributed to the ester bond. The adsorption band at 1636 cm^{-1} is attributed to the C=C stretching vibration, which confirms the formation of 4-(4′-(3, 4, 5-tris (2-(2-methoxyethoxy) ethoxy) benzyloxy) phenylazo) benzyl methacrylate. Fig. 5b shows the ^{1}H NMR spectra of 4-(4′-(3, 4, 5-tris (2-(2-methoxyethoxy) ethoxy) benzyloxy) phenylazo) benzyl methacrylate. The chemical shifts are illustrated as follows: ^{1}H NMR (δ, ppm, $CDCl_3$): 7.93-7.87 (m, 4H, Ar-H), 7.52-7.50 (m, 2H, Ar-H), 7.08-7.06 (m, 2H, Ar-H), 6.69 (s, 2H, Ar-H), 6.19 (s, 1H, =CH-), 5.62 (s, 1H, =CH-), 5.27 (s, 2H, -CH_2O-), 5.04 (s, 2H, -CH_2O-), 4.19-4.18 (t, 6H, -OCH_2-), 3.87-3.81 (t, 6H, -CH_2O-), 3.72-3.67 (t, 6H, -OCH_2-), 3.56-3.54 (t, 6H, -CH_2O-), 3.38-3.36 (s, 9H, -OCH_3), 1.99 (s, 3H, -CH_3). The peak area ratio of vinyl peak m (peak m. Fig. 5b) and methylene peak l (peak l. Fig. 5b) is 1 : 2 and no impure peak is observed, indicating the pure dendronized monomer is obtained.

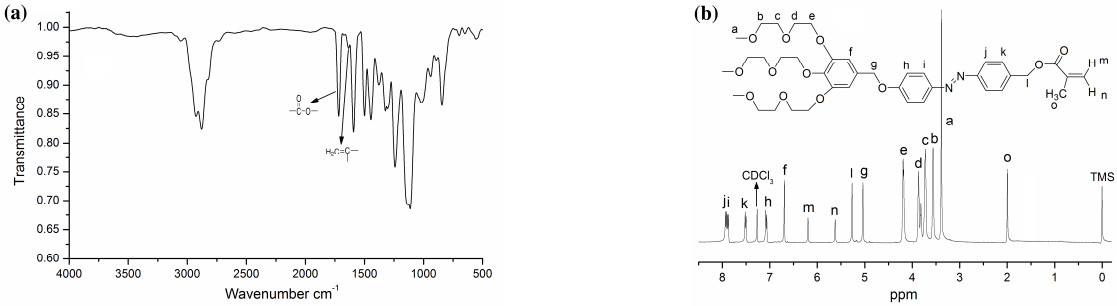

Fig. 5 FTIR spectrum (a) and ^{1}H NMR spectra (b) of the dendronized monomer, 4-(4′-(3, 4, 5-tris (2-(2-methoxyethoxy) ethoxy) benzyloxy) phenylazo) benzyl methacrylate.

Phase transition behaviors

Fig. 6 shows the DSC traces of intermediate compound 3 and dendronized monomer. From Fig. 6, it will be seen that each of the compounds has only a phase transition, which attributes to the glass transition. Melting point and LC phase transition are not observed during the heating and cooling process.

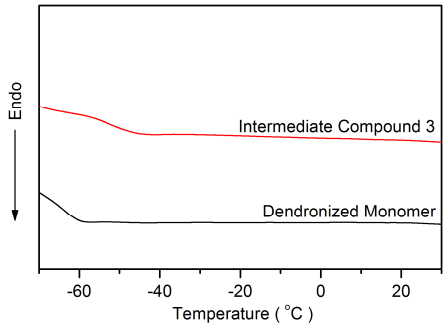

Fig. 6 DSC curves of intermediate compound 3 and dendronized monomer during the second heating at a rate of 10 °C min^{-1}.

The lower critical solution temperatures (LCSTs) of intermediate compound 3 and dendronized monomer in deionized water were measured by visual method. Fig. 7 illustrates the appearance changes of 5.0 mg ml^{-1} intermediate compound 3 and dendronized monomer in deionized water during phase separation. When intermediate compound 3 was dissolved in pure deionized water at the concentration of 5.0 mg ml^{-1} at room temperature, it was turbid; however, when the temperature was decreased to 15 °C (LCST), it became a transparent solution, meaning the occurrence of phase transition (Fig. 7a). Just as expected, dendronized monomer aqueous solution at the concentration of 5.0 mg ml^{-1} did also exhibit a sharp and rapid phase transition around 11 °C (LCST) (Fig. 7b).

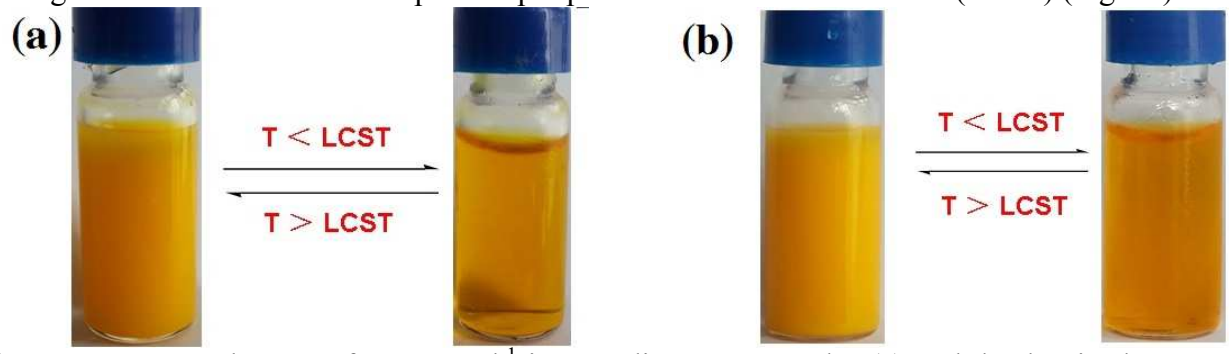

Fig.7 Appearance changes of 5.0 mg ml^{-1} intermediate compound 3 (a) and dendronized monomer (b) in deionized water during phase separation.

Summary

A novel thermoresponsive dendronized monomer bearing azobenzene moiety, 4-(4′-(3, 4, 5-tris (2-(2-methoxyethoxy) ethoxy) benzyloxy) phenylazo) benzyl methacrylate, has been successfully synthesized. The chemical structures of intermediate compounds and dendronized monomer were confirmed by FTIR and ^{1}H NMR. The phase transition behaviors of these intermediate compounds and dendronized monomer were investigated. The intermediate compound 3 and dendronized monomer both showed remarkably reversible thermoresponsive phase transition behaviors.

Keywords: Temperature controlled, Ionic liquid, Multi-walled carbon nanotubes (MWCNT)

Abstract. We synthesized a novel polymeric functional ionic liquid (IL), i.e. poly[(N-isopropylacrylamide)-co-(ionic liquid)] (P(NIPAAm-co-IL)), which can make multi–walled carbon nanotubes (MWCNTs) well dispersed in water. This method is a noncovalent technique, and the resulting solution was sensitive with temperature.

Introduction

Carbon nanotubes (CNTs) have attracted much attention due to their superior chemical, mechanical, thermal and electrical characteristics [1,2]. The application of CNTs require them to be firstly dispersed in solvents in many case [3]. But the dispersion of CNTs in solvent, especially in water, is still a challenge work because CNTs are prone to aggregate. It is well known that water is the cheapest solvent. But CNTs is difficult to be dispersed stably in water due to mutual poor compatibility. Both covalent [4,5] and noncovalent [6,7] techniques can solve this problem. With covalent technique, concentrated nitric acid is usually used to treat CNTs, and the conjugated structure of CNTs are destroyed, consequently impairs some of their important properties[4,5]. Compared with the covalent technique, noncovalent technique is a milder route. Generally, some agents such as surfactants are used in this route [8,9], but only moderate effects were obtained in the filed hybrid materials.

Recently, ionic liquids (ILs) have been studied extensively due to their potential applications as green solvents, reusable catalysts, separation and extraction media, electrolytes, heat-transfer fluids and so on [10,11]. ILs have strong solubility of organic and inorganic materials including CNTs. Fukushima firstly reported that pristine single-walled (SWCNTs) could be dispersed in imidazolium ion-based ILs through a possible cation-Π interaction [12]. Later Chen et al. confined 1-butyl-3-methylimidazolium hexafluorophosphate [bmim][PF_6] in multi-walled CNTs (MWCNTs) [13]. It is worth noting that the dispersion of CNTs in ILs is a noncovalent technique, and the inherent properties of CNTs suffer no change by this method. However, at present, ILs are expensive. Thus it is important to decrease the amounts of ILs to disperse CNTs.

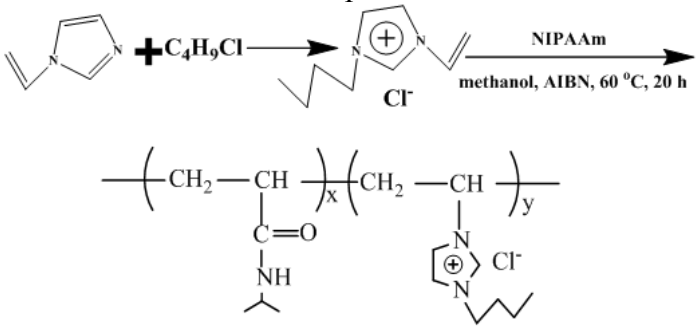

Fig. 1 The procedure for the synthesis of P(NIPAAm-co-IL)

Zhou et al. found that MWCNTs can be dispersed stably in water with the aid of a very small amount of amido-functionalized ILs. But the recycling of ILs and MWCNTs was not mentioned in their route [14]. Marcilla et al. proved a reversible phase-transfer method for dispersion of CNTs in

water with the aid of special polymeric ILs. In their system ILs and MWCNTs could be recycled effectively. But the reversible phase-transfer process was controlled by the salt additives, which increased the cost and introduced impurity. In this work, we synthesized a novel temperature-responsive polymeric functional ionic liquid poly[(N-isopropylacrylamide)-co-(ionic liquid)] (P(NIPAAm-co-IL)) to disperse MWCNTs in water.

Experimental Section

The synthesis of the polymeric functional IL is illustrated in Fig. 1. Firstly, ionic liquid momomer (ILM) 1-vinyl-3-butylimidazolium chloride was prepared from the N-alkylation of 1-vinylimidazole with 1-chlorobutane. Then the P(NIPAAm-co-IL) was synthesized by the free radical copolymerization of the ILM and isopropylacrylamide (NIPAAm) using azobisisobutyronitrile (AIBN) as the initiator in methanol at 60 ºC for 20 h, the structure of P(NIPAAm-co-IL) was characterized by NMR (Fig. 2) .

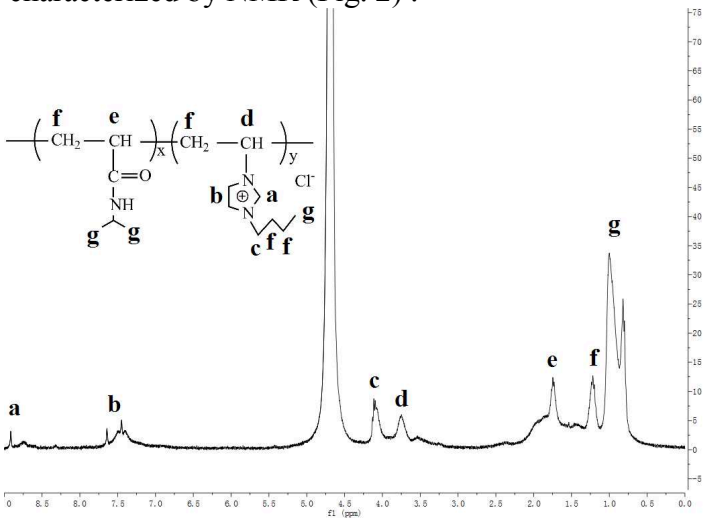

Fig. 2 ^{1}H-NMR Spectra of P(NIPAAm-co-IL) (solvent: D_2O, n_N/n_I = 2:1)

Results and Discussion

The temperature-responsive property of P(NIPAAm-co-IL) aqueous solution (mass percent: 5%) with different mole ratio of NIPAAm to ILM (n_N/n_I) is shown in Fig. 3. No temperature-responsive phenomenon was observed when the n_N/n_I = 2:1. As n_N/n_I = 8:1, the temperature-responsive property can be observed. While n_N/n_I was increased to 10:1 or higher, the temperature-responsive property of the solution gets obviously. Moreover, the critical solution temperature (LCST) of P(NIPAAm-co-IL) is 32 ºC in our system.

At room temperature, P(NIPAAm-co-IL) aqueous solution (mass percent: 5%, n_N/n_I = 10:1) can disperse a certain quantity of MWCNTs (mass ratio of MWCNTs/P(NIPAAm-co-IL) = 1:5), and the resulting solution can exist stably more than six month. It has been accepted that the imidazolium ions possibly interact with the Π-electron network of the CNTs by the way of a "cation-Π" interaction [12,14]. When the mass ratio of MWCNTs/P(NIPAAm-co-IL) = 1:5 or lower, enough imidazolium ions stabilize MWCNTs. Likewise, the P(NIPAAm-co-IL)/MWCNTs suspensions shows temperature responsive property. When the temperature is 32 ºC or higher, the solution become greyish white, and some MWCNTs gradually precipitate (Fig.3).

In order to further understand the temperature response of P(NIPAAm-co-IL) in the presence of MWCNTs, the UV-vis absorbance of P(NIPAAm-co-IL) aqueous solution were carried out (Fig. 4). It can be seen that there is a significant increase in absorbance of the P(NIPAAm-co-IL) aqueous solution about 30 ºC due to the coil-globule transition of poly(N-isopropylacrylamide) (PNIPAAm).

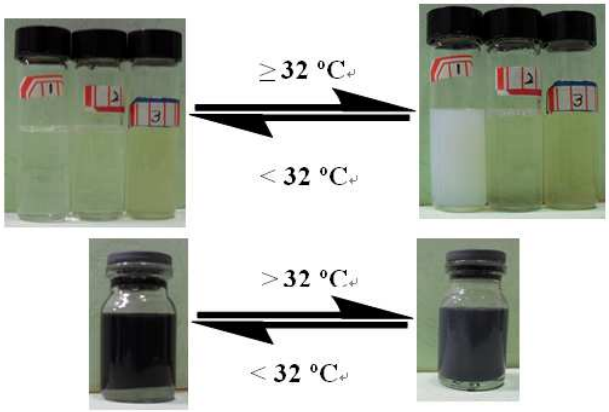

Fig. 3 The temperature-responsive property of P(NIPAAm-co-IL) with different n_N/n_I: 10:1 (1), 8:1 (2), 2:1 (3); and the temperature-responsive property of P(NIPAAm-co-IL)/MWCNTs aqueous solution.

The aqueous P(NIPAAm-co-IL)/MWCNTs suspensions also show a small but significant increase at 30 ºC, which corresponds to the LCST of P(NIPAAm-co-IL). Therefore, the temperature-responsive characteristics of P(NIPAAm-co-IL) are still retained in the presence of MWCNTs.

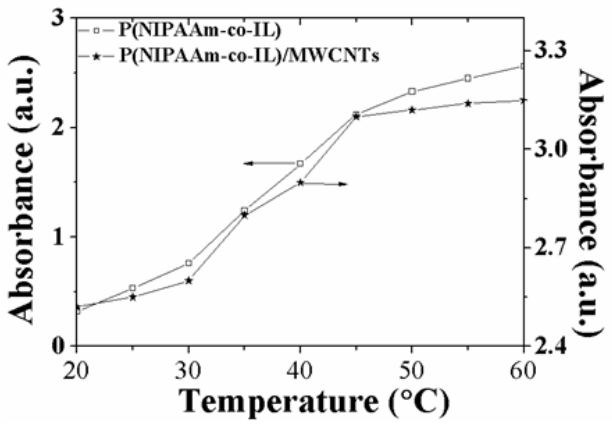

Fig. 4 Absorbance at 200 nm for the aqueous P(NIPAAm-co-IL)/MWCNTs suspension and the aqueous P(NIPAAm-co-IL) solution.

Furthermore, the aqueous P(NIPAAm-co-IL)/MWCNTs suspension were dried at temperatures below and above LCST (i.e., 20 and 60 ºC, respectively) to form thin composite films. The morphologies of the composite films show a high degree of aggregation in the films dried at 60 ºC (Fig. 5). Meanwhile the electrical conductivity of these composites were high for films dried at 60 ºC at all the concentrations studied (i.e., 10 and 20 wt % MWCNTs) (Table 1). High electrical conductivity of the film dried at 60 ºC is due to better nanotube-nanotube contacts resulting from

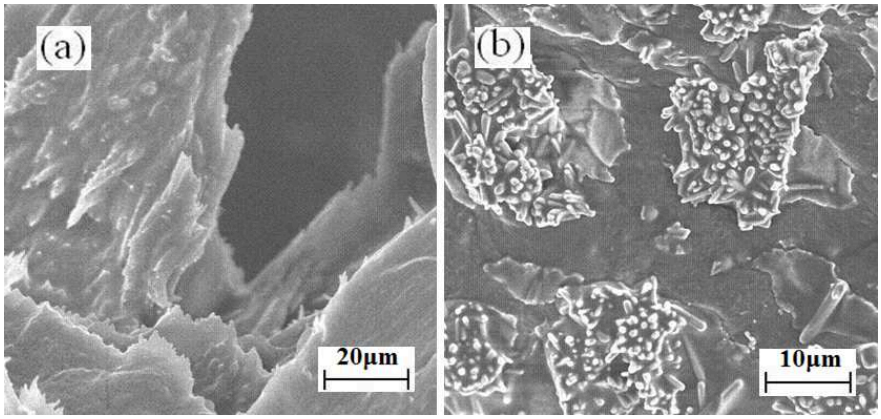

Fig.5 SEM micrographs of P(NIPAAm-co-IL)/MWCNTs composites dried at: (a) 20 ºC and (b) 60 ºC. (mass ratio of MWCNTs/P(NIPAAm-co-IL) = 1:5)

Weaker polymer-nanotube interaction. It leads to a more aggregated and heavily networked microstructure, which is much like the case in the liquid suspension. While the film dried at 20 ºC, the close association between polymer and MWCNT restricts the electron flow by creating an insulating layer and reducing the contact points between MWCNT.

Table 1. Electrical conductivity of P(NIPAAm-co-IL)/MWCNTs composites

wt% MWCNTs	Drying Temp (ºC)	Electrical Conductivity (S m^{-1})
10%	20	0.24
10%	60	0.43
20%	20	1.25
20%	60	3.68

Conclusion

In conclusion, we synthesized a polymeric functional IL P(NIPAAm-co-IL), which can make MWCNTs well dispersed in water. The resulting solution was sensitive with temperature. This system would have potential applications in polymer nanocomposite preparation.

Keywords: Titanium alloy, laser rapid repair, crack, scratch, cladding.

Abstract. Titanium alloy structure is an indispensable structure in aviation industry. It has high sensitivities for gap, scratch and other surface defects. Therefore, it is easy to produce various damages, such as crack, scratch and break. This paper describes a new laser rapid repair system which solves the technical problem that modern aviation titanium alloy components can not be repaired by conventional repair techniques. The rapid repair for titanium alloy components can be achieved by means of it. Meanwhile, the repair quality of aviation titanium alloy structure can be improved.

Introduction

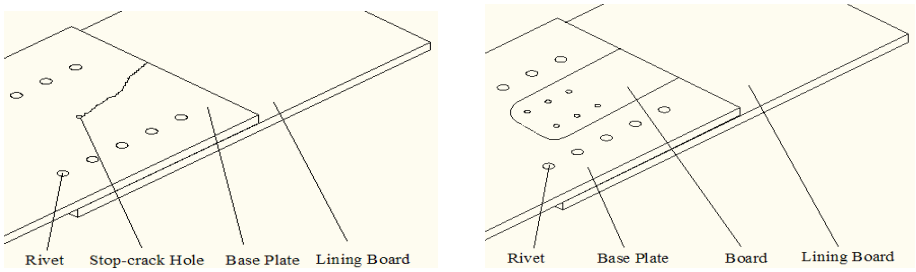
On account of low density, high specific strength, corrosion resistance and other characteristics, titanium alloy is an excellent structural material in the aviation industry. It has many disadvantages, including poor processing property and difficult machining in cold working, easy absorption impurities (such as carbon, hydrogen and nitrogen) in hot working, poor abrasion resistance and complex production process [1]. Therefore, it is easy to produce various damages such as crack and fracture, and so on. Limitations of repair techniques on traditional machining exist in aviation industry. For instance, large deformation, 50% performance loss and serious fatigue damage can be generated after repair on account of the large heat input of welding process in traditional TIG welding [2]. Therefore, it is very urgent to develop an advanced repair technology.

Disadvantages of Traditional Process

Welded Structure. Titanium has low thermal conductivity and excellent welding performance. However, heat-affected zone of matrix generated by argon arc welding, which makes it form overheated structure, takes shape brittle precipitate phase and decreases the strength of the joint [3]. For differences of operator proficiency in argon arc, welding joint can be formed in different welding height and width, which can result in different degrees of stress concentration in welding. Uneven grain structure, broad heat-affected zone, and inevitable porosity defect exist in welding. For instance, porosity is one of the most common welding defects in titanium alloy welding process. The formation of porosity can be caused by O, N, H, CO and HO. These defects lead to different plasticity and mechanic performance of static and dynamic in weld joint, heat affected zone and base substrate, which decreases the bearing capacity of part and affects the service life of part [4].

Riveted Structure. On account of the stress concentration existing in the riveted structure, and the aging of engineering structure, fatigue crack will present near the rivet, and sudden destruction structure will be occur with the crack propagation to a certain degree, which leads to disastrous consequences. Traditional methods of repair process can be adopted, including the supplement method and patching method. The repair process of the supplement method includes first hitting the

stop-crack hole, then restoring the original stiffness and strength of the base plate riveted by the lining board with the same thickness and material. The repair process of patching method includes cutting the part surrounding crack, filling the cutting part with a board, and connecting the board with the original structure by a lining board, which is shown in Fig. 1. It can be seen that structure strength is weakened by the rivet hole in traditional titanium alloy riveting process. It is difficult for titanium connecting rivets to form the pier head at the room temperature directly. Titanium alloy rivet is made to enter into the superplastic temperature zone by heating so as to deform [5].



Supplement method Patching method

Fig. 1 Riveting repair of titanium alloy structure

New System and Process of Rapid Repair for Titanium Aero Structure

A System of Rapid Repair for Titanium Aero Structure. Laser rapid repair is an advanced manufacturing technology based on laser cladding and laser rapid prototyping. It has the unique advantages including controllable energy, no mold, near net forming and high degree of flexible, which offers a new repair method to complex and expensive parts. It utilizes molten pool that is formed by the laser irradiation to combine cladding material and undone repair substrate in the process [6]. The key of laser processing technology quickly repairing titanium aircraft components is to design a laser repair system meeting the repair demand. The system has the advantages including good appearance of weld, small heat affected zone and deformation zone, simple operation and high efficiency, high energy density and welding, which is especially suitable for high melting point and high reflectivity titanium alloy structure repair.

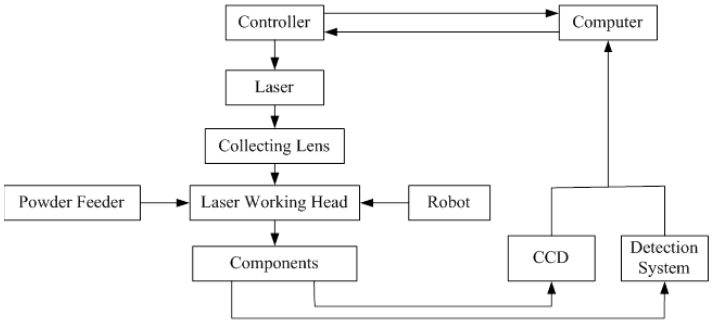


Fig. 2 A system of rapid repair for titanium aero structure

The working principle of laser system is shown in Fig. 2. It consists of controller, PC machine, laser device, collecting lens, robot, laser working head, powder feeding system, CCD, detection system, etc. Laser emitted by laser device enters into the working head through collecting lens, as a heat source for welding. According to the shape and size of the structural damage, the laser working head in a three-dimensional robot motion control system moves automatically. Powder grains under the action of the carrier gas are sent out from the feeding device. Under the constraint of the spray powder feed channel, they are jetted out in accordance with a certain track, falling into the molten pool formed by the laser irradiation. Meanwhile, the signals, such as flow, temperature, pressure, sound, displacement and speed sensed by the detection system and welding surface topography

conversed by CCD are displayed on a PC. The laser working head and feeding device are automatically adjusted by the controller so as to achieve the dynamic response of the control of conveying speed and throughput accurately and timely.

Process of Repair Technology

Aviation titanium component is repaired by the system.
Process is shown as follows:
(1) Testing the scope and trend of the crack by the non-destructive flaw detection technique and measuring tools, and evaluating the damage. The basic method of repair is determined according to the detection result.
(2) A programming of scanning line for laser working head.
(3) Cleaning up welding parts, removing oil, water, sewage and surface oxide.
(4) According to the programs and sensor signals, the working system consisting of the laser working head, powder feeder and robot breaks holes and welds automatically.
(5) Checking the welding and effects through the CCD, trimming the surfaces by re-programming.
(6) Non-destructive detection after welding.

Laser Rapid Repair for Titanium Piece

Laser Welding Repair of Crack. $CWCO_2$ laser can repair penetrating crack of thin-walled titanium parts. The process is shown in Fig. 3.

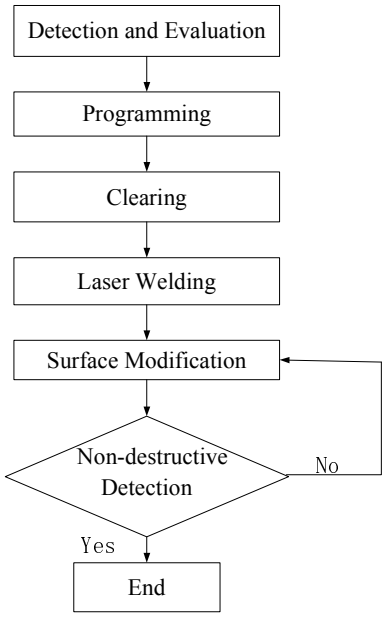

Fig. 3 Process of welding

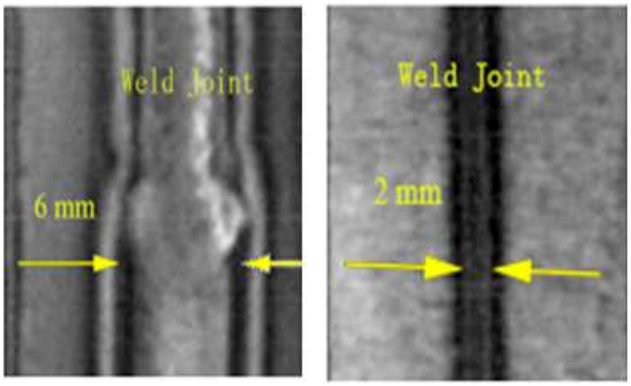

(a) Manual arc welding; (b) $CWCO_2$ laser welding

Fig. 4 Two kinds of welding

The comparative morphology of the two kinds of seam welding is shown in Fig. 4. It includes (a) manual arc welding and (b) $CWCO_2$ laser welding (power 800 W, velocity 90 mm / min, spot 1.8 mm, argon gas protection). It can be seen that the weld joint width of $CWCO_2$ laser welding is about 60 percent less than that of manual arc welding. Laser welding has many advantages including smooth surface, stable quality, minimal deformation, pulsed laser welding narrower and the almost indiscernible weld heat-affected zone. Experiments show that laser welding is the ideal means of the repair of titanium alloy sheet crack [7].

Laser Cladding Repair of Crack. Based on the discrete/accumulation principle of rapid prototyping, laser cladding repair is that the metal powder is melted by a laser beam and then piled up one by one on the damage structure under the control of programs. Based on this, the full metal components can be formed. The essence of laser cladding repair technique is a three-dimensional laser cladding accumulation under computer control. A non-penetrating crack usually occurs in non-thin-walled parts, the depth of which cannot be measured directly. According to the shape of the defect, the crack will be gradually removed by polishing, then repair model is established hierarchically in the groove after grinding by the laser cladding. The process is shown in Fig. 5. Eventually, the damaged structure is rebuilt and the performance of the structure is restored to meet the requirements of size, shape and roughness.

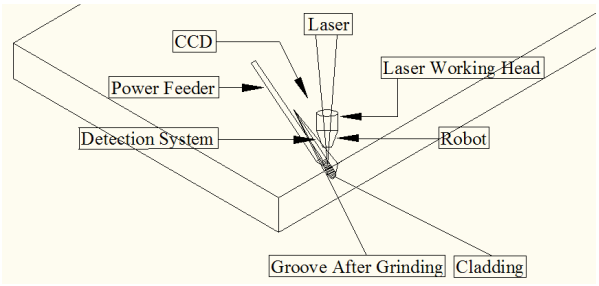

Fig. 5 Method of laser cladding repair for crack

Conclusions

A new laser-based rapid repair system is designed in this paper, which solves the problem that the damaged aviation titanium alloy components cannot be rapidly repaired by conventional repair technique. The penetrating cracks of thin-walled titanium parts can be rapidly repaired by laser welding and the non-penetrating cracks of no-thin-walled titanium parts can be rapidly repaired by laser cladding repair. This provides a guarantee for titanium alloy components damage rapid repair.

Keywords: Brominated Flame Retardants, Supercritical Carbon Dioxide Fluid Extraction, GC-MS.

Abstract. A method of supercritical CO_2 fluid extraction gas chromatography-mass spectrometry(GC-MS)was developed for the determination of 2 novel brominated flame retardants(BB-153 and TBECH)) in flexible polyurethane foam. The optimum conditions as follows: extraction temperature: 60℃, pressure:30Mpa, CO_2 mass flow rate: 8g/min ,flow rate of methanol entrainer: 3mL/min and extraction time: 60min. The calibration curves were linear in the range of 0.1 ～50μg/mL with correlation coefficient of 0.9995～0.9999 and detection limits (S/N=20) of 0.05μg/mL. The average recoveries of the target compounds in sample were in the range of 97.3%～98.8%(BB-153), 99.2%～105.8% (TBECH)respectively. The results showed that this method was sensitive, reliable and environmental for the determination of 2 novel brominated flame retardants(BB-153 and TBECH)) in flexible polyurethane foam.

Introduction

Fire retardant properties (BFRs) of building material is the necessary measure to control the risk of fire. Brominated flame retardants has excellent flame retardant performance, widely used in electronic products, textiles, plastic products. The most common BFRs are Polybrominated diphenyl ethers (PBDEs), Hexabromocyclododecane(HBCD) and tetrabromobisphenol A (TBBPA) [1].It is estimated that the annul demand of BFRs is 7.0×10^7kg-8.7×10^7kg in China, with an increasing rate of 7%-8% [2-3]. The abuse of BFRs leads them widely exist in various environmental media (air, soil, rivers and lakes) and organisms[1,4]. Studies show that certain BFRs have a greater harm on the human nervous system, endocrine system and reproductive system [5]. The Stockholm convention has put Hexabromobiphenyl, Tetrabromodiphenyl ether and pentabromodiphenyl ether (commercial pentabromodiphenyl ether) [6].Some new halogenated flame retardant, such as 1,2-bis(2,4,6-tribromophenoxy)ethane (BTBPE) was used instead of disabling the brominated flame retardants, novel halogenated flame retardant increases steadly [7].

Detection of BFRs mainly concentrated in the electronics, textiles, plastics. Soft furniture flame retardant polyurethane foam for brominated flame retardants in detection has been not reported. On the sample pre-treatment, Textiles are usually through ultrasonic extraction , electronic products are usually through Soxhlet extraction. Then all the samples arer detected by GC-MS. CO_2 has excellent liquid dissolved and gaseous diffusion in supercritical state [8]. Supercritical CO_2 fluid extraction is not only used for the extraction of volatile oil, but also gradually increased in the flame retardants. The supercritical CO_2 fluid extraction technology was first introduced into plastic brominated flame retardants[9-10]. Abdel mnim Altwaiq [11] develped the research on the extraction separation of DecaBDE from HIPS .Some researches such as extraction of TPP from electronic printed circuit board by supercritical carbon dioxide and removal of polybrominated diphenyl ethers from plastic solution by supercritical carbon dioxide were also reported in China[12-13]. The representative brominated flame retardants (BB-153 and TBECH) were studied, through one step foaming, in combination with GC-MS detection. Compared with traditional Soxhlet extraction, this method

results are reliable, can be used for detecting the brominated flame flexible flame retardants in polyurethane foam.

1Test

1.1 Materials

Polyether glycol (PPG-5623, hydroxyl value of 28.0 KOH mg/g with a degree of functionality of 3, CSPC); polyether polyol (POP CHF-628, hydroxyl value of 28.0 KOH mg/g with a degree of functionality of 3, Jiangsu Changhua Polyurethane Science & Technology Co., Ltd); toluene diisocyanate (TDI 80/20, degree of functionality of 3, Shanghai Basf Coating Co., Ltd); dibutyltin dilaurate (PUCAT L-33, Foshan City Puhui New Material Co., Ltd); stannous octoate (YOKE T-9, Jiangsu Yoke Technology Co., Ltd.); niax silicone L-540/STL DR; 2,2',4',4',5,5-hexabromodiphenyl ether (BB-153); 1,1,2-dibromo-4-(1,2-dibromoethyl)-cyclohexane (TBECH, J&K Scientific Ltd); triazine triamine phosphate (MPOP, Hefei Fine Collection Institute of Chemical Industry); and deionized water (self-made).

1.2 Appratus

GC-MS（7890A 5975C， Agilent ）, Supercritical CO2 Fluid Extraction（Meichen High Separation Technology Company）, Rotary Evaporator（RE-52AA Shanghai Yarong Biochemical Instrument Factory）, Ultrasonic extraction instrument.

1.3 Preparation

According to the formula [4], the PPG, POP and deionized water were all combined in a 1000 ml plastic beaker. Dibutyltin dilaurate, niax silicone, stannous octoate and the corresponding flame retardant were then added and stirred with a mechanical mixer for 2 h with the material temperature kept at 25 °C. Finally, TDI 80/20 was added, and the mixture was stirred at high speed for 4 to 5 s and then immediately poured into the natural foaming moldwith the temperature maintained at 25 °C for 24 h. The densities of the prepared materials were controlled to be 50 ± 2 kg/m3.

1.4 Sample pretreatment

1.4.1 Supercritical fluid extraction：The samples were broken with scissors, weigh accurately 1.0g, Wrapped with thin non-woven fabric, then put sample in the extraction pool. Optimize the extraction conditions with different temperature, pressure and entrainer. The flame retardant was extacted from the treated polymer sample by dissolving it in 100mL on a suitable solvent for 1min and filtering it through a membrane disk filter (0.2μm).External standard quantification was used for the procession.

1.4.2 Soxhlet extraction：The samples were broken with scissors, weigh accurately 1.0g, the sample was extracted with 70mL toluene in the soxhlet extraction for 4h ， keeping the reflux times at 5-6 times per hour. After cooling to room temperature, condensed the solution into 10mL by Rotary Evaporator .the extraction solution was filtered through a membrane disk filter ((0.2μm). The solution was analized by GC-MS. External standard quantification was used for the procession.

1.4.3 Ultrasonic extraction：The 1.0g sample into 20mL toluene, ultrasonic 30min. Collection of extraction solution. Constant volume to 20mL, GC-MS analysis from the 1mL to the sample bottle.

1.5 GC-MS Analysis：HP-5 Trace Analysis 5% Phenyl colum（30 m x 250 μm x 0.25 μm），Temperature programmed：Initial oven temperature of 100℃,holding 1min，then ramped at 30℃/min to 300℃, and hold for 2min.Thecarrier gas, UHP helium,was set at constant flow, 3mL/min. The mass analysis was performed in the electron impact ionization(EI) mode. Ionization energy：70eV，Ion source temperature：230℃，The maximum value：270℃，Quadrupole temperature：150℃，The maximum value：200℃.

2 Results

2.1 Optimization of pretreatment conditions

2.1.1 Time

Temperature and pressure are the key parameters of supercritical fluid extraction. At certain temperature, Elevated temperature increased volatility and the rate of diffusion of solute, improves

the extraction efficiency, Meanwhile, Elevated temperature also reduces the density and the solvent power of the supercritical fluid. Typically, higher extraction temperature is better for larger molecular weight and polar compounds. Brominated flame retardants have larger molecular weight. TBECH belongs to weak polar molecule. Figure 1 shows the efficiency of extraction BB-153 and TBECH with condition as follows: pressure 30MPa, CO_2 volume flow rate: 8g/min, entrainer: methanol (flow rate 3mL/min), extraction time: 60min. The results show that, The extraction efficiency of two compounds increased gradually With the increase of temperature between 20℃～60℃. The extraction efficiency was highest at 60 ℃.

2.1.2 Pressure

In critical state，Density of material is sensitive to the change of pressure. Small change of pressure will cause the larger change in fluid density. While the increase of the density will also lead to improve solubility. So separation can be achieved through adjusting the solubility. But higher pressure will cause adverse effect to apparatus. Extraction was proceed as follows: temperature at 60℃, CO_2 volume flow rate: 8g/min, entrainer: methanol (flow rate 3mL/min), extraction time: 60min. The extraction efficiency as shown in Figure 2 increased with the increase of extraction pressure. But when the extraction pressure exceeds 30MPa, the extraction efficiency close to steady state, and more high boiling point compounds was extracted.

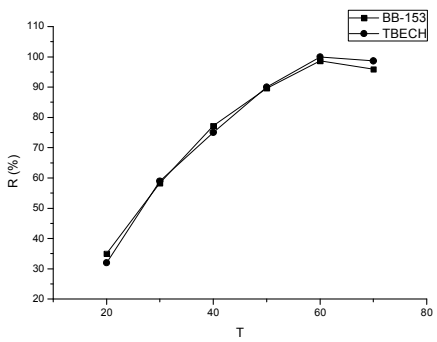

Figure 1 Effect of temperature on brominated retardants in supercritical CO_2 fluid extraction

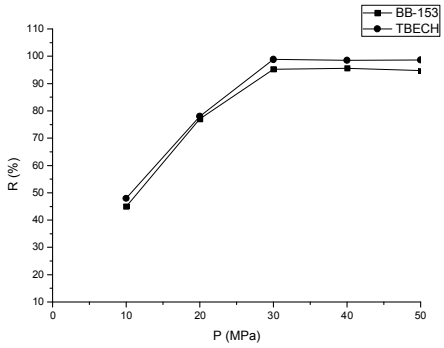

Figure 2 Effect of pressure on brominated flame flame retardants in supercritical CO_2 fluid extraction

2.1.3 Entrainer

Supercritical CO_2 extraction is very suitable for non-polar and polar compounds. For the polar compounds, the extraction can be achieved by adding entrainer .Without any entrainer, the efficiency of BB-153 and TBECH reached only 32.8% and 32.5% respectively. Because of the weak polar, we extracted the sample using different entrainer such as methanol, toluene, and 1-propanol.The result showed highest efficiency with methanol. Due to the small polar, toluene and CO_2 dissolve each other.

So the optimum condition as follows: xtraction temperature: 60℃, pressure:30Mpa, CO_2 mass flow rate: 8g/min ,flow rate of methanol entrainer: 3mL/min and extraction time: 60min.

2.2 Qualitative and quantitative

Blank samples were injected onto GC-MS. The Mass spectra showed in Figure 3-4. For BB-153 and TBECH, the most abundant was used for quantitation (m/z 627.5 for BB-153 and m/z 267.0 for TBECH). Total ion current chromatogram of two compounds showed in Figure 5. Total BB-153 and TBECH can be analyzed using GS-MS, but 4 isomers(α, β, γ, δ) of TBECH has to be done by LC-MS-MS, however, studies t determine the degree of interconversion between isomers have not been completed [8,15].

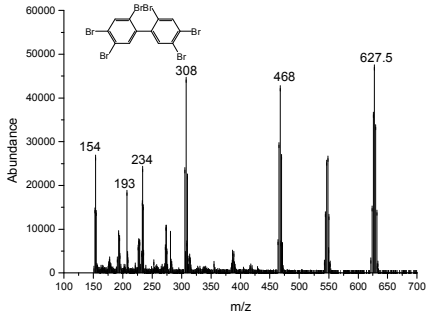

Figure 3 Full scan mass spectra of BB-153

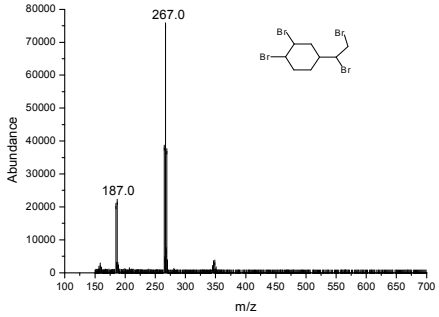

Figure 4 Full scan mass spectra of TBECH

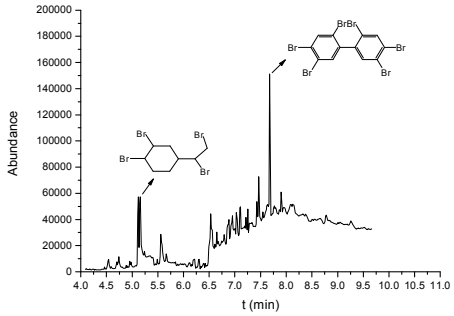

Figure 5 Total ion current chromatogram of BB-153 and TBECH

2.3 Relevant parameters

Toluene as solvent, two compounds were arranged in 0.1, 0.5, 2, 5, 10, 20, 50 μ g/mL standard solution. Accurate draw 1mL standard solution to the sample bottle, draw the standard curve in the chromatographic conditions, The linear correlation coefficient was 0.9995～0.9999， Table 2 showed the results.

Table 2 Relevant parameters of BB-153 and TBECH

No.	compound	CAS No.	Linear range μg/mL	*r*	Detection limit μg/mL
1	BB-153	59080-40-9	0.1-50	0.9995	0.05
2	TBECH	3322-93-8	0.1-50	0.9999	0.05

2.4 Precision and Recovery

After ultrasonic extraction, Soxhlet extraction, and super critical CO_2 extraction, precision and recovery were obtained. The details were showed in Table 3.

Table 3 Precision and Recovery

Project	Recovery（%）		RSD（%）（n=5）	
	BB-153	TBECH	BB-153	TBECH
Ultrasonic extraction	83.8-85.6	85.4-87.5	5.0	4.2
Soxhlet extraction	91.2-92.3	92.5-93.6	3.0	2.8
super critical CO2 extraction	32.8-33.8	32.5-33.2	4.8	3.6
super critical CO2 extraction（methanol as entrainer）	97.3-98.8	99.2-105.8	3.2	8.0

2.5 Detection of real sample

The retardant flexible polyurethane foam buying from market was detected with this method. Both BB-153 and TBECH were not found.

3 Conclusion

In this work, we set a method of super critical CO2 extraction/GC-MS to detect the content of brominted flame retardant , using flexible retardant polyurethane foam as target. The results showed that this method was sensitive, reliable and environmental for the determination of 2 novel brominated flame retardants(BB-153 and TBECH)) in flexible polyurethane foam.References

Keywords: FPUF，Brominated Flame Retardants，Combustion Performance.

Abstract. Different flexible polyurethane foams (FPUF) were prepared with one step method. Combustion performance of them were tested throughout oxygen index (OI), cone calorimeter (Cone). The results showed that flame performance prepared by 10% wt brominated flame retardants, and 10% wt MPOP was better. In irradiance 30kW/m^2, sample thickness 50mm conditions, heat release rate peak seprarately decreased to 284.0 kW /m^2 and 270.8 kW /m^2. In the coordination of N and P, the FPUF adding MPOP showed ideal flame retardancy .It is worth noting that when the content of MPOP exceeds 10%, the physical performance decreased rapidly with the increases of brittleness and hardness.

Introduction

Due to accelerated indurstrialization and urbanization, building materials have obtained dramatic growth in china. Polyurethane (PU) has special structure and excellent performance, so It has been used in great demand.Since as product of Polyhydric alcohol (R-OH) and isocyanates (RN = C = O), the combustion process of polyurethane (PU) releases large amounts of toxic gases, sothat PU is highly fire risking materials [1].The flexible polyurethane foam (FPUF) is type of polyurethane molding material with porous structure which is the most flammable polyurethane material.

the flammability of the FPUF limits its application in many fields, and therefore, enhancing urgency of the flame retardancy research of FPUF [2] . Flame retardants of FPUF include reactive flame retardant and additive flame retardant according to the effect between flame retardants. and the base materials. The reactive flame retardant effects persistently with more thermal stability，but difficult to apply in industrial production；In contrast, the additive flame retardant which is the earliest used with simple production process，is widely used until now [3]. In this paper, Flexible polyurethane foams (FPUF) were prepared with one step method by choosing different additive flame retardants foam. Then combustion performance of FPUF were tested throughout oxygen index (OI), cone calorimeter (Cone) and smoke toxicity .The result will provide reference for proper selection of flame retardants.

Material	Ingredient/g
PPG	75-90
POP	10-25
TDI 80/20	31.5-40
Stannous octoate	0.2-1.5
Dibutyltin dilaurate	0.1-0.5
Niax silicone	0.6-1.0
Flame retardants	2.0-15.0
Deionized water	1.8-2.0

1.4 Test Method

1.4.1 Oxygen Index tested According to ISO 4589-2:1996, with test temperature （23±2）℃, humidity at (50%～55)% and sample size 100mm×10mm×10mm.

1.4.2 Heat release rate tested according to ISO 5660-1:2002，with irradiance setting at 30kW/m^2 and sample size 100mm×100mm×50mm.

2 Results

2.1 Oxygen Index(OI)

Because of The flame retardancy of POP itself, the oxygen index of blank FPUF still reached 21.6% without addition of flame retardant . The oxygen index of FPUF adding RDT-9 (10%) is higher than that adding MA(10%). Since the phosphorus flame retardant effected by building the main barrier of air and combustion products,and Chlorine flame retardant is by radical dilution of oxygen in the air. So the cooperative effect can achieve better than only use of MA. In the halogen flame retardant, brominated flame retardants is particularly prominent. The oxygen index reached 24.6% through adding HBB(5%) and TBECH(5%)， In contrast, The oxygen index adding MPOP(10%) is best，reaching 25.2%，which attributed to the cooperation of N- P. Charring of solid phase and isolation of air phase improve flame retardant effect.

2.2 Heat Release Rate(HRR)

Heat release rate refers to the thermal radiation intensity of presupposition, the rate of heat release on per unit area after ignition, with unit kW/m^2. Heat release rate can be divided into average heat release rate and peak heat release rate (pHRR). The average heat release rate has practical function on the early evaluation of the contribution of the material itself, early flame retardant and fire safety design[5] . The peak heat release rate(pHRR) is one of the most important fire characteristic parameters of materials.The irradiance 30kW/m^2 is closest to the actual fire conditions. So 30kW/m^2 was determined in the cone calorimeter test. Figure 1 shows the heat release rate curve of the four specimen in the irradiance of 30kW/m^2.Among them, the heat release rate of blank FPUF is the highest. pHRR of FPUF adding RDT-9 and MA is reduced but still high, both excceeding

500kW/m^2. Meanwhile FPUF adding HBB(5%)and TBECH(5%) reduced to 284kW/m^2. pHRR of FPUF adding MPOP(10%) becomes the lowest, which indicate 5% lower than the brominated flame retardant.

2.3 Total Heat Release（THR）

The total heat release of cone calorimeter test refers to the total heat release per unit area of the sample after complete combustion with unit MJ/m^2. Total heat release is an important parameter for thermal hazard evaluation of actual material. The more total heat material release, the more potentially fire dangerous the material is. From Figure 2, THR of Blank FPUF is far greater than the other four kinds of prepared FPUF with additive flame retardant. In the combustion process of FPUF adding MPOP, Is obviously to observe the surface expansion phenomenon. The isolation of charring increase the effect of the flame retardant, which leads to the minimum total heat release.

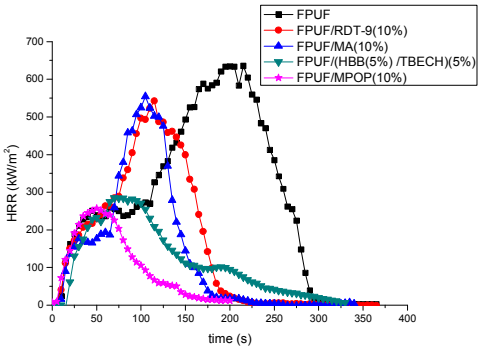

Figure 1 The heat release rate curve

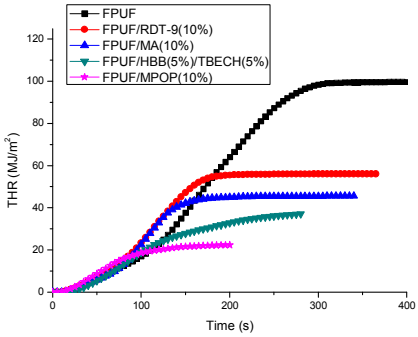

Figure 2 The total heat release curve

2.4 Mass loss rate（MLR）

The weight sensor supportting sample pool in the cone calorimeter records automatically. the mass loss rate, using five point finite - difference method. This parameter is closely related to the heat release rate, ratio of extinction area, and the formation rate of CO. The material burns more violent. With lager mass loss rate Figure 3 shows the mass loss rate curve of different of FPUF adding different flame retardants with the mass fraction 10%. Among of them, the one adding MPOP(10%) shows the least mass loss rate, the burning slow relatively. Through the observation of the combustion process, All the specimen were ignited within 5s. Furthermore all of the surface participate combustion, With rapidly shrinking. Carbonization quality after combustion residues from 3% to 5%. Adding flame retardant changes the mass loss rate relatively, but in the high irradiance, surplus quality shows less difference. The charring rate of FPUF adding MPOP is the highest.

2.5 Specific Extinction Area（SEA）

Specific extinction area refers to smoke produced capacity per unit mass after decomposition evaporation of combustible sample, with unit m^2 /kg. From Figure 4, FPUF adding HBB and TBECH demonstrate strong smoke producing ability, with following incomplete combustion phenomenon. This proves the smoke hazards of the brominated flame retardants, which pose high health risks to humans[6]. FPUF adding MPOP produce least smoke, which show ideal flame retardancy.

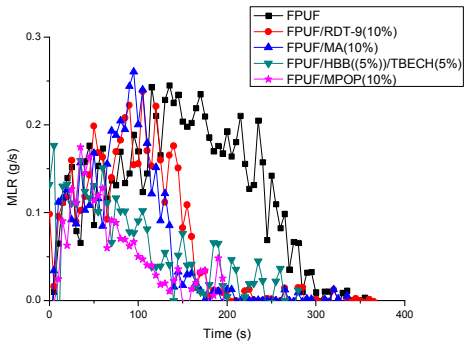

Figure 3 The mass loss rate curve of different FPUF

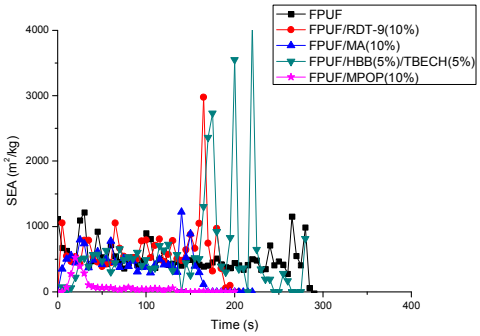

Figure 4 SEA curve of different FPUF

3 Conclusion

Flexible polyurethane foams (FPUF) were prepared with one step method by choosing different additive flame retardants foam. Combustion performance of FPUF were tested throughout oxygen index (OI), cone calorimeter (Cone) and smoke toxicity. The results showed that flame performance prepared by 10% wt brominated flame retardants, and 10% wt MPOP were better. In the coordination of N and P, the FPUF adding MPOP showed ideal flame retardancy .It is worth noting that when the content of MPOP exceeds 10%, the physical performance decreased rapidly with the increases of brittleness and hardness.

Halogenated flame retardant has high smoke risk, which has been gradually phased out. Effect of Nonhalogen, and coordinative flame retardant is prominent, which has become the future development direction of flame retardant products. For preparation FPUF composite material with excellent comprehensive performance, Developing coordination and functional research of organic, inorganic additive type , intumescent flame retardant and reactive halogen free flame retardant research will represent the general trend.

Keywords: Al matrix composites, Whisker, Hot extrusion, Mechanical properties, Microstructure

Abstract. The study investigates the influence of different fraction of Mg_2B_2O5 whiskers (5, 10, 15 and 20vol.%) on the microstructure of the hot extruded composite as well as on the mechanical properties in the same condition. The results indicate that the process is available for producing the composite, image analysis shows the whisker tends to cluster together with increasing content of reinforcement. When the content of the reinforcement is 10%, the composites exhibit the best mechanical properties, meanwhile, it demonstrate cluster is unfavorable to the improvement of properties of materials. The ductile failure of 6061Al matrix, the reinforcement fracture and the whisker-matrix interface debonding acted as the main mechanism of fracture nucleation.

Introduction

Magnesium borate whisker reinforced aluminum matrix composites have attracted much attention [1], because of its low cost and good properties such as high specific strength and modulus, low coefficient of thermal expansion, and so on. It is considered to be a potential candidate in many fields, for example, aerospace, relaxation and automobile.

Powder metallurgy (PM) processed composites with good mechanical properties can be produced when the reinforcements are homogeneously distributed in the matrix [2]. However, clustering is difficult to avoid in the case of a large reinforcement concentration or a large particle size ratio of matrix powders to reinforcement powders [3]. Many investigations demonstrated that the clustering could degrade the tensile properties of the composites [4]. However, mechanism responsible for the degradation of tensile properties is still not well understood.

The principal objective of this current investigation as to determine how the microstructural parameters, such as the whisker volume fraction and extent of clustering affect the tensile properties and fracture roughness of $Mg_2B_2O_5w$/6061 Al matrix composite.

Experimental procedure

The atomized 6061Al powders with average diameter of 48 μm and composition in mass%: 0.8~.12 Mg, 0.4~0.8 Si, 0.15~0.4 Cu, balance Al, were used as a matrix, and $Mg_2B_2O_5$ whiskers with average diameter of 0.5~1.5 μm and length of 10~80 μm were added as the reinforcement. The SEM images of them are shown in Fig. 1. It can be seen that the Al particles are in general rounded with relatively uniform particle size, and the whiskers are commonly long cylinders with smooth superficial aspect.

The material used was 6061 aluminum alloy reinforced with 5, 10, 15, and 20 vol.% of $Mg_2B_2O_5$ whisker. The composites were prepared by a PM route which involves blending, cold compaction and extrusion (at the extrusion ratio of 25:1 and 530℃). In this manner, extruded bars, 8mm in diameter and ≈1000mm in length, were obtained. Die wall lubrication was applied by brushing a thin layer of zinc stearate lubricant. Fig. 2 shows schematically the geometry of the extrusion press and the extrusion die and a powder blend compact ready for extrusion.

The microstructures and tensile fractographs of the powders and extruded composites were observed using scanning electron microscopy (SEM, JSM-6700F). The density of each of the samples

was measured using Archimedean principle. The measured density was compared to the value obtained using rule-of-mixtures so as to determine the volume fraction of porosity. Tensile testes were performed at room temperature and an initial strain rate of $1\times10^{-3}s^{-1}$ on an Instron1195 tensile tester. Tensile specimens with a gauge diameter of 5 mm and a gauge length of 25 mm were machined from the extruded samples along the axis direction, in accordance with the Chinese National Standard GB6397-86.

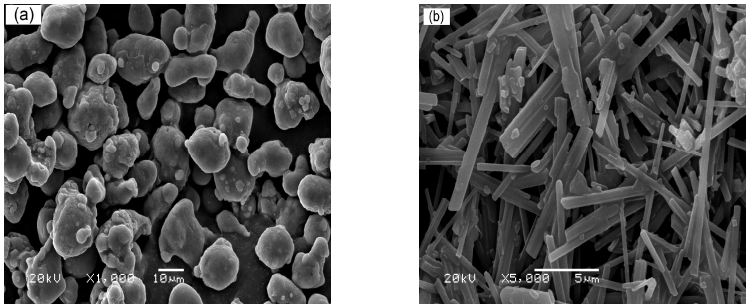

Fig. 1 SEM images of 6061 powders and $Mg_2B_2O_5$ whiskers (a) 6061Al powders; (b) $Mg_2B_2O_5$ whiskers

Results

Microstructure. The $Mg_2B_2O_5$w distributions in various composites are shown in Fig. 2. Compared with the original state of whiskers, its aspect ratio has been relatively reduced. For the composites with a volume fraction of 5~10 vol.%, the $Mg_2B_2O_5$w were homogeneously distributed (Fig. 2a~b). For the composites with higher reinforcement contents (15 vol.%), although the distributions of the whiker were still relatively homogeneous, clusters began to appear (Fig. 2c). When the content of reinforcement reached 20 vol.%, a large amount of whiskers came into contact with each other, as shown in Fig. 2d, some pores induced by cluster could be seen in the whisker clusters.

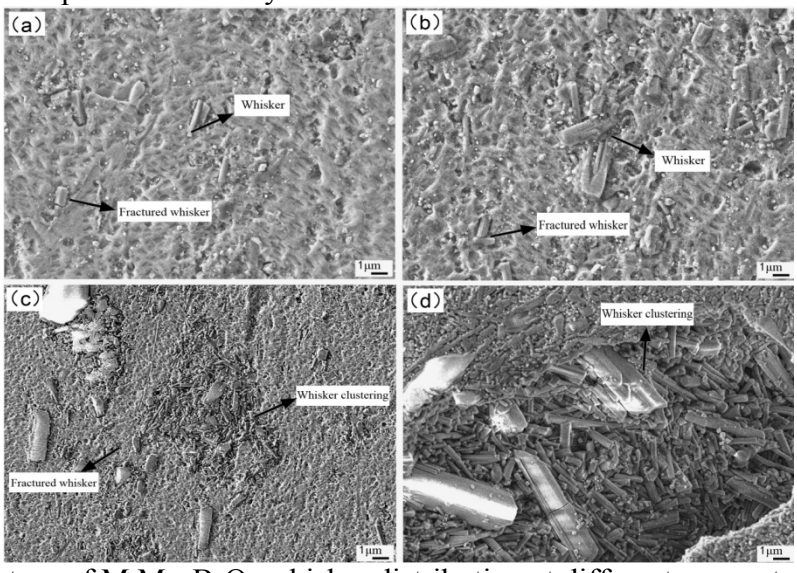

Fig. 2 Microstructure of M $Mg_2B_2O_5$ whisker distribution at different concentrations (a)5vol.%, (b)10vol.%, (c)15vol.%, (d)20vol.%.

Fig. 3 shows the theoretical and measured density of the composites with different reinforcement concentrations. The measured density deviated from the theoretical one when the reinforcement concentration was larger than 10 vol.% due to the porosity formation in the clusters. And the deviation was especially obvious at the content of 20 vol.% due to increased porosity formation, which was in accordance with SEM observations (Fig. 2d).

Mechanical properties and fractographs. Fig. 4 shows the variation of ultimate tensile strength (σ_b), 0.2% offset strength ($\sigma_{0.2}$) and elongation (δ) with the vol.% of whisker. In comparison with the unreinforced alloy, the $Mg_2B_2O_5$w/6061 composites present significantly higher strength for the whole content range. Meanwhile, the volume fraction of the $Mg_2B_2O_5$ whisker was found to have a

significant effect on the tensile properties of the composites, both σ_b and $\sigma_{0.2}$ started to decrease beyond about 10 vol.% of $Mg_2B_2O_5w$. Elongation of the composites always decreased with increasing reinforcement content. This figure clearly shows that the amount of the reinforcement plays a significant role in controlling the tensile properties of the composites. It is also important to note that the whisker clustering also have a significant effect on the tensile properties of the composites. As shown in Fig. 4, the yield strength and ultimate tensile strength started to decrease at a higher whisker contents, mostly due to the increased amount of clustering. This seems to be especially true for the composite containing 20 vol.% of whisker when the strength is expected to be much higher than at lower whisker levels. But, it is lower due to the increased amount of clustering.

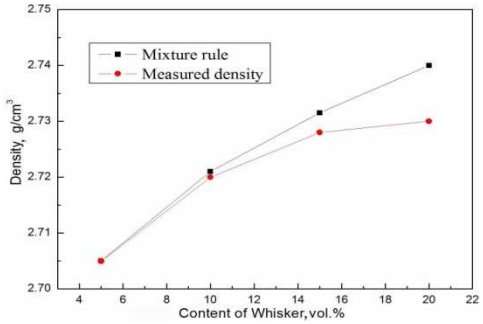

Fig. 3 Density at different $Mg_2B_2O_5$ whisker reinforcement concentrations

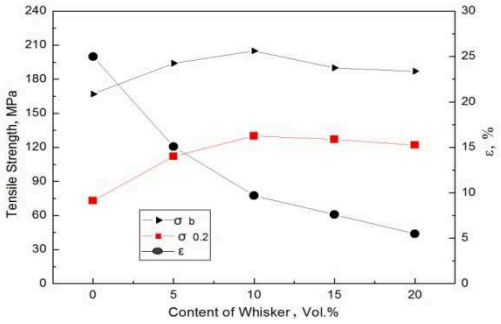

Fig. 4 The effect of content of whisker on the mechanical properties of the composites

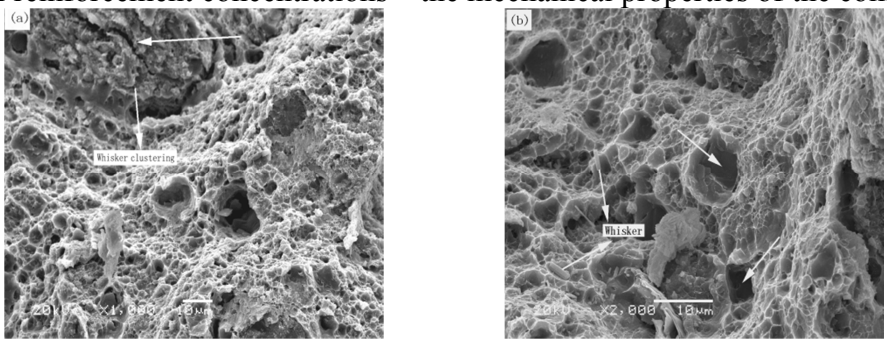

Fig.5 Fracture surface morphologies of $Mg_2B_2O_5w$/6061Al matrix composites

Even though the composites did not exhibit much ductility on a macroscopic scale, SEM fractographs indicated that the fracture occurred by a locally ductile mechanism. Fig. 5 shows the morphologies of the tensile fracture surfaces of the 10 vol.% composite.

Discussion

Fracture. As it can be easily observed form the fractographs (see Fig. 5(a)), some clustered regions, $Mg_2B_2O_5$ whiskers in the composites, cracked in a direction perpendicular to the fracture surface. The high magnification view of the fracture surface shows some whiskers pulled out from aluminum matrix and lots of small dimples (see Fig. 5(b)). So the regions nearby the reinforcement act as points of weakness in the material and probable position for the initiation of tensile failure.

It is considered that the difference of thermal expansion coefficients between whisker and Al alloy matrix leads to the large residual stress of joints and high density dislocation in the extruded composites, and all of these go against the plastic deformation of the matrix [5,6]. Under an applied load, the matrix is placed under great constraint with an inability for strain relaxation to take place. This cause the onset of void nucleation and propagation, which take place at a lower far field applied strain. So the regions nearby the reinforcement act as points of weakness in the material and probable position for the initiation of tensile failure.

Since the reinforcement is less restricted to plastic deformation for the matrix, the composites with lower reinforcement content are good at the elongation, as shown in Fig. 4. For the composite with 15 vol.% $Mg_2B_2O_5$ whisker, it present relatively low elongation, and its fractograph showed some large pits due to the whisker clusters, which indicated that the whisker clusters were an important reason for the composite failure. Otherwise, decohesion at the matrix/whisker interface and ductile fracture

in the matrix were also the fracture mode of the composites. In general, the performance of the composites depend on the specific fracture mode.

Strength. The mechanical properties of Al matrix composites are mainly attributed to the interface bonding state and distribution of whiskers in the matrix [7,8]. First of all, with excellent interface bonding strength, the load could transfer from the weaker matrix, across the matrix/reinforcement interface, to the typically higher stiffness reinforcement. In this manner, strengthening could take place by the reinforcement "carrying" much of the applied load. The interfacial bonding strength of the composites is improved effectively according to the improvement of the extrusion ratio (25:1) in the previous study. As shown in fig. 3b, the whisker distribution in the matrix is homogeneous for the 10 vol.% $Mg_2B_2O_{5w}$/Al matrix composite, and the ultimate tensile strength (σ_b), 0.2% offset strength ($\sigma_{0.2}$) increased by 19% and 44%, separately, compared with extruded 6061 Al alloy; However, the strength of the materials started to decrease beyond about 10 vol.% of $Mg_2B_2O_5w$.

That is because there are other factors that affect the strength of the composites, including the clustering and lower aspect ratio of the whisker. As shown in fig.2(c~d), when the whisker content is more than 10 vol.%, clustering in the matrix is more obvious and serious, otherwise, some pores induced by cluster, demonstrated by density test, could be seen in the whisker clusters for the 20 vol.% $Mg_2B_2O_5w$/Al matrix composite. Decreased plasticity and fracture toughness are attributed to the stress concentrations in the matrix at the poles of the reinforcement and/or at the regions of reinforcement clusters [9]. Furthermore, when the load was transferred from the matrix to the clusters, the clusters firstly cracked because of internal defect and the load at other region increased abruptly, therefore, the strength of the composites inevitably decreased [10].

Conclusions

(1). Processing methods that produce microstructures with a more uniform distribution of reinforcements could potentially result in composites with improved mechanical properties.

(2). The strength of the composites was not always increased with increasing volume fraction of the reinforcements, among other factors, to the presence of clustered whisker, especially for an whisker concentration higher than 10 vol.%.

(3). During the tensile deformation, the whisker clustering produced great effects on the mechanical response of the matrix and the whiskers.

(4). 4The whisker clustering region would promote early the interface debonding and void formation in the ductile matrix.

Key words: BHA; BHT; TA; LDPE; antioxidant

Abstract. Low density polyethylene (LDPE) films contains BHA, BHT or BHA, BHT, TA were successfully produced by extrusion. Three types of antioxidant films that were L(LDPE), LBB(LDPE+0.5%BHA+0.5%BHT), and LBBT(LDPE+0.5%BHA+0.5%BHT+0.5%TA) was designed. The Mechanics, moisture permeability, scanning electron microscopy (SEM) and antioxidant activity of the film were detected. The results showed that antioxidant consisting of BHA, BHT and TA has a better compatibility with LDPE film. The antioxidant film has a better performance on mechanical strength and the rate of DPPH radical scavenging ability, but poor to water vapor transmission rate.

Introduction

In recent years, with the food security problems which caused by the abuse of food additives gradually become the focus, and the vacuum or modified atmosphere packaging cost too much in practical application, the domestic and foreign scholars have put research emphasis on the antioxidant packaging materials, a novel alternative that is being researched is the incorporation of antioxidants into polymers with the aim of being transmitted to oxygen-sensitive food, improving its chemical stability[1].

BHA is a fat-soluble antioxidants that stabilize to heat and suitable for fatty foods or fat-rich foods. BHT can act as antioxidants by high stability, great antioxidant activity and heat resistance, and it has also been developed as a excellent source to be used as additives in film to protect them from oxidation during polymer manufacturing/processing[2]. Tartaric acid (TA) is kind of antioxidant that can increase the effectiveness of preservation by chelating metals[3].The objectives of the present work was to develop an active antioxidant film to improve food preservation by the addition of two types of antioxidants that are 0.5%BHA+0.5%BHT and 0.5%BHA+0.5%BHT+0.5%TA in LDPE, by blending and flat extrusion. The new polymer developed was characterized by the analysis of its barrier properties, optical, mechanical properties, scanning electron microscopy (SEM), thermal, and its antioxidant efficiency.

1 MATERIALS AND EQUIPMENT S

1.1 Materials and Reagents

The Low Density Polyethylene(LDPE) was kindly provided by China Petrochemical (Shanghai, China). Food grade absolute 2(3)-tert-Butyl-4-methoxyphenol (BHA), 2,6-di-tert-butyl-4- methyl phenol (BHT), 2,3-Dihydroxybutanedioic acid (TA) were purchased from Biotechnology Co., Ltd., Zhengzhou days (Zhengzhou, China). 2,2-Diphenyl-1-(2,4,6-trinitrophenyl)hydrazyl (DPPH) was supplied by Biochemical Technology Co., Ltd. Shanghai Jing Pure (Shanghai, China). Ethanol (95% purity) was acquired from Sinopharm Group Reagents (Shanghai, China).

1.2 Film Preparation

Three kinds of antioxidant film were designed in this study: L(LDPE), LBB(LDPE+0.5%BHA+0.5%BHT), LBBT(LDPE+0.5%BHA+0.5%BHT+0.5%TA), in which 0.5% was mass fraction and the remainder was LDPE. The process of film preparation was as follows: LDPE+Antioxidants⟶Twin Screw Extruder⟶Blending⟶Flat Extrusion⟶Preservative Film.

2 MEASUREMENT INDICATORS

2.1 Water vapor Permeability

The water vapor permeability (WVP)of the films were determined at 100% RH and 37.8℃ using an PERMATRAN-W1/5 (Mocon, Germany) in accordance with the method of ASTME398[4].

2.2 Mechanical Properties

The mechanical properties of films including elongation at break (EB) and tensile strength (Ts) were carried out at 25℃ and 50%RH. Experiments were performed using a Tensile Testing Machine DCP-KZ30 (Chengdu, China) according to the method of ASTM-09[5].

2.3 Scanning Electron Microscopy (SEM)

S3400N (Hitachi) scanning electron microscope was used to research the morphology of films. The samples were mounted on the specimen holder with aluminum tape and then sputtered with gold in sputter coater for 30s at 20mA[6]. All samples were determined using an accelerating beam at a voltage of 20.0 kV.

2.4 Thermal Analysis

Thermogravimetric analyses were performed using a NETZSCH TG209/F3 thermal analyzer (German). The samples (ca. 5mg) were heated in 100μL ceramic crucible from 35℃ to 900℃ under a nitrogen atmosphere at 15℃/min to measure and record any volatilization of volatile compounds, as well as the degradation temperatures of the films developed[7].

2.5 Antioxidant Efficiency

Antioxidant activities of the films containing antioxidants were determined by the DPPH method. The tests were carried out as follows: a 12 cm^2 piece of each sample and 100ml of 95% ethanol (area-to-volume around 6dm^2/L) were placed in tubes which covered with aluminium foil to protect the contents from light to undergoing the process of extraction, and then the tubes were conserved at 65℃ for 3h[8]. The DPPH scavenging activities of extraction solutions was measured according to the method of Zheng lin[9].

3 RESULTS AND DISCUSSION

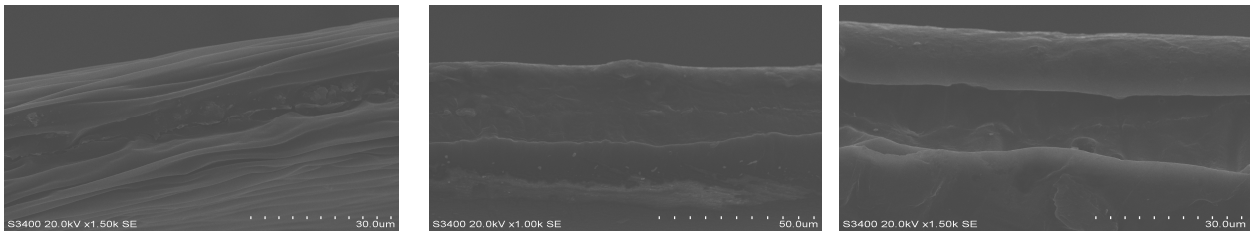
3.1 Mechanical Properties And Water Vapor Permeability

Table.1 Test results of mechanical properties and water vapor permeability of the film

Group	Thickness (mm)	Ts (Mpa)	EB (%)	WVP ($\times10^{-15}g\cdot m^{-1}\cdot s^{-1}\cdot pa^{-1}$)
L（control）	0.018	12.76	56.4	7.679
LBB	0.032	13.23	51.7	6.869
LBBT	0.024	17.25	42.2	6.564

Mechanical properties and water vapor permeability test results are shown in Table.1. Ts of LBB and LBBT increased from 12.76 to 13.23(3.7%) and from 12.76 to17.25(35.2%)Mpa compared to L(control), respectively, after addition of BHA, BHT and BHA, BHT, TA. Conversely, EB of LBB and LBBT decreased from 56.4% to 51.7% and from 56.4% to 42.2%. Based on these results, it can be concluded that the incorporation of antioxidants improved its rigidity and reduced the effectiveness of its flexibility. The reason for this phenomenon may be owing to crosslinking of the molecular chain of LDPE resin under the condition of high temperature during the process of modified granulation and flat extrusion. Thus, it is very difficult for the occurrence of slip between the molecular chain, reducing EB and increasing Ts of the films .Table.1 also sets out the water vapor permeability (WVP) of the films. All the films containing antioxidants had lower WVP values than the pure LDPE film. TA incorporation caused the decrease in WVP. Presumably because the active agents enhance the molecular interactions of LDPE that make the film more uniform compact, thus preventing water molecules through effectively.

3.2 Scanning Electron Microscopy(SEM)



L **LBB** **LBBT**

Fig.1. SEM micrographs of cross-section of films

SEM micrographs representative of all films are presented in Fig.1. The pure LDPE film showed a smooth, compact and continuous microstructure with no irregularities compared to antioxidants-containing films. The film adding antioxidants images displayed that antioxidants distributed evenly in the resin base material, no bubbles, and there are no stress concentration caused by antioxidants gather. These phenomenon concluded that antioxidants have a preferable compatibility with film under high temperature.

3.3 Thermal Characterization

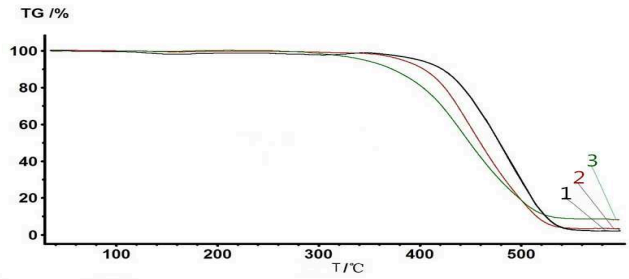


Fig.2 TGA curves of film

The results are shown as Fig.2, the drastic mass loss of pure LDPE materials occurred in a main step at a temperature between 400℃ and 500℃. The highest temperature of the experiment is set to 600℃, control film almost degraded completely, no residue, while the experimental groups were part of residues at the end of the experiment. The thermal decomposition process of LDPE is a chain reaction triggered by free radicals, the polymer chain will fracture into carbon free radicals randomly during the process of reaction, and the carbon free radicals react to generate low molecular weight hydrocarbons further[10], the antioxidants that were added into the films will have the effect of scavenging free radicals, leads to the weaken of free radical reactions, thus the thermal decomposition of the film is inhibited. From the change trend of the entire thermograms, the whole films have a lesser mass loss under the condition of 320℃, relatively stable, are suitable for the preservation of normal usage.

3.4 Antioxidant Efficiency DPPH radical has been extensively used to measure the ability of compounds as free radical scavengers. This method is based on the inhibition of the DPPH radical that is a stable free radical by antioxidants, and consequently decolorize in the present of antioxidants resulting in a decline in absorbance values. The antioxidant activity of different films is shown in Fig.3. The control film exhibited radical scavenging activity of 2.30% on DPPH. Films with antioxidants showed a higher level of radical scavenging activity with values of 20.79 and 18.63% for LBB and LBBT, respectively. The results demonstrated that the DPPH scavenging activity of the film increased significantly with the incorporation of antioxidants. The film that contained TA(LBBT) was found less effective against quenching DPPH radical in comparison with LBB may be due to the addition of TA that made the connections between LDPE polymer chains more dense so that the release of antioxidants sustained certain restrictions.

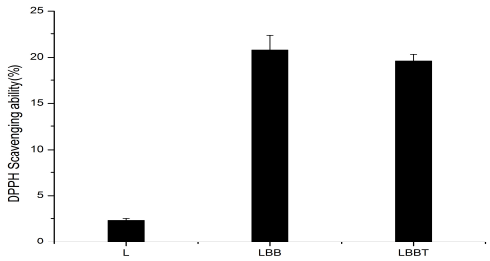

Fig.3 Figures of DPPH radical scavenging ability of film

4 Conclusions

The study results revealed that the LDPE film incorporated with BHA, BHT and TA in concentration of 0.5% has a perfect potential for application as a antioxidant film. LDPE film showed some antioxidant activity, which was remarkably improved by the addition of antioxidants. This incorporation made the film uniform density, increased the film tensile strength, reduced the water vapor transmittance coefficient and improved the heat resistance, which demonstrated that the film containing BHA, BHT and TA could be used as a kind of food packaging material.

Keywords: Photoswitches; Lanthanum nitrates; calix[4]arene derivatives; photochromic spiropyrans

Abstract. The spectroscopic behavior of a photochromic compound 5, 11, 17, 23-tetra-*tert*-but yl-25, 27-bis(1',3',3'-trimethyl-6-nitrospiro-[2-H-1-benzopyran-2,2'-indoline]-8-methoxycarbonylmethox y)-26,28-dihydroxycalix[4]arene (**1**) and its complex with lanthanum nitrate was described. Compound **1** has typical photochromic properties for its two spirobenzopyran groups. The complexation spectroscopic behavior has been investigated in anhydrous acetonitrile by UV-vis, fluorescence spectra and ESR spectra. The results obtained proved the formation of complexes and indicated that the spectroscopic behavior of the supramolecular system could be regulated by light. The system might be used as *on-off* switches.

Introduction

Photochromism was firstly brought forward in the fifties of the twentieth century by Fischer and Hirshberg [1, 2]. In the past fifty years, people have developed many potential applications as photochromic materials, optical storage, optical memories and optical switches. Spiropyran system is one of the earliest and the most extensive systems. Under the irradiation of ultraviolet light (or in dark conditions), the closed, colorless, neutral spiropyran (SP) forms are isomerized to their open, colored, zwitter-ionic merocyanine forms (MC). Meanwhile, the s-p hybridization of a single C atom changes to p-conjugation over the whole molecule. The characteristics indicate its potential applications in photoswitchable molecular devices [3-8]. Calixarenes, with three-dimensional cavities, which are regarded as the third supramolecular receptor, are popular building blocks in supramolecular chemistry [9, 10]. Their derivatives can selectively bind a variety of molecules and ions. Therefore, we chose calix[4]arenes as host frames and spirobenzopyrans as light responsible groups to establish a receptor which not only might bind guests but also spectroscopic behavior of the supramolecular system might be regulated by light. This kind of design idea would be useful in photoswitchable devices.

Results and discussion

Compound **1** carries two spirobenzopyran groups so it should have typical photochromic properties. Therefore, we measured UV-vis spectra of compound **1** under three different conditions (under dark conditions, upon ultraviolet light irradiation and visible light irradiation). As expected, the acetonitrile solution of compound **1** (0.05 mM) had no absorption above 400 nm upon visible light irradiation because the spirobenzopyran groups of compound **1** were in closed, colorless forms (Calix-2SP) under this condition. Then, the solution was kept in the dark for 16 minutes. It turned to purple and had maximum absorption at 555 nm in the visible region which caused by part conversion of closed forms to open, colorful forms (Calix-2MC). After the solution was irradiated by ultraviolet light for 20 minutes, the absorbance at 555 nm was increased by about two folds for further conversion from closed forms to open forms. Visible light irradiation could almost make the absorbance decrease to zero again. This reversible photochromic processes were described in Figure 1.

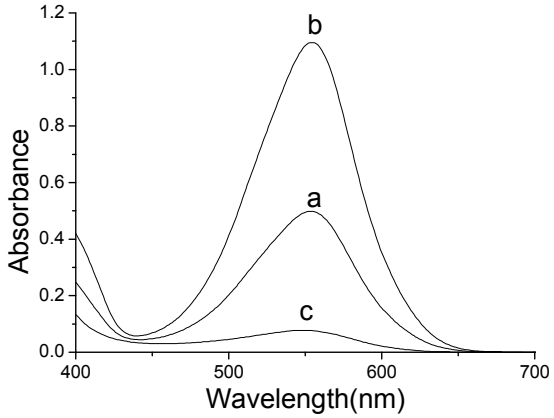

Fig. 1 Photochromism of compound **1** in acetonitrile in the dark 16 min (a); upon UV irradiation 20 min (b); and then upon visible light irradiation 10 min (c).

As mentioned above, our interest is to develop a light responsible supramolecular system whose spectroscopic behavior could be regulated by light stimuli. Our above results have proved that the synthetic receptor **1** possessed good photochomic properties as well as binding ability with lanthanum ions. Next, we would like to investigate whether its spectroscopic behavior could be regulated by light. The mixed solution of compound **1** (0.05 mM) and an equivalent lanthanum nitrates was kept in the dark. Eleven hours later, the absorbance at 487 nm increased by more than two folds (Curve a, Figure 2). Then, the above solution was irradiated by visible light. Just as expected, a remarkable decrease was observed as shown in Figure 2 (Curve b). UV irradiation caused the absorbance increase again (Curve c, Figure 2). What's more, its spectrum almost returned to its initial absorbance after it was kept under dark conditions for 11 hours again (Curve d, Figure 2). For low energy of the mercury lamp (15 W), curve c is under curve d. These results demonstrate that light can modulate spectroscopic behavior of **1**-La^{3+} supramolecular system. Proposed photoswitching processes are described in Scheme 1.

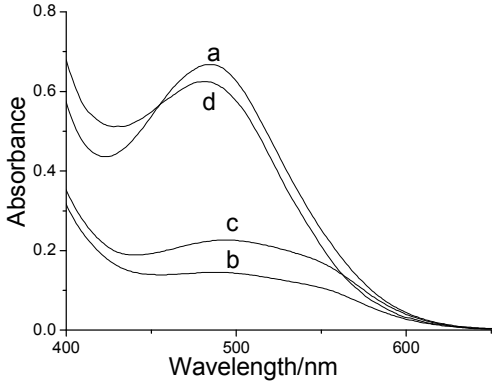

Fig. 2 UV-vis absorption spectra of the mixture of compound **1** (50 μM) and 1 *equiv.* lanthanum nitrates in the dark 11h (a); upon visible light irradiation 5 min (b); and then upon UV irradiation 25 min (c); finally in the dark 11h (d).

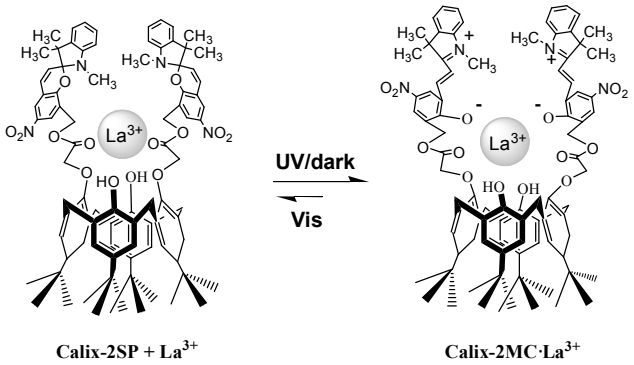

Scheme 1. Proposed photoswitchable binding processes of compound **1** and lanthanum ions.

Emission spectra studies provided consistent results with those of absorption spectra. It was reported that closed forms of spiropyran derivatives have no emission while open forms can emit weak light at about 635 nm [11]. The open forms of compound **1** can emit light at 635 nm (Curve a, Figure 3). After the addition of lanthanum nitrates, a remarkable hypsochromic shift (about 40 nm) occurred in the emission spectra companied with intensity increase (Curve b, Figure 3). The shift just accords with the blue shift in the absorption spectra. Then, the mixture of compound **1** and La^{3+} was irradiated by visible light and a significant decrease of emission intensity was observed (Curve c, Figure 3). This result is corresponding to the curve b in Figure 3. The open forms of compound **1** (Calix-2MC•La^{3+}) were isomerized to its closed forms (Calix-2SP) which have no emission.

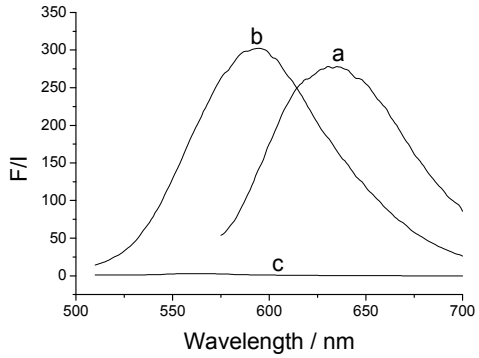

Fig. 3 Emission spectra of compound **1** (20 μM) before (a); and after the addition of 20 μM $La(NO_3)_3$ in acetonitrile after 48h in dark (b); then irradiated by visible light for 15 min (c).

Another interesting experimental result was obtained by studies on ESR (Electron Spin Resonance). After the addition of lanthanum nitrates to the acetonitrile solution of compound **1**, the mixture was irradiated by 355 nm and then 532 nm light. Quite different signals were detected as shown in Figure 5. There were no detectable signals in control experiments of compound **1**'s solution and lanthanum nitrates' solution under the same conditions. These results might be due to the binding interaction between the open forms of compound **1** and La^{3+}, which could attributed to the energy level splitting of the unpaired electron in lanthanum atomic orbits induced by magnetic field. After the irradiation of visible light, the interaction disappeared so the mixture was just like two independent system of compound **1** and lanthanum nitrates which both have no ESR signals at this condition. Weak signals (right, Figure 4) were due to the incomplete conversion of open forms to closed forms upon visible light irradiation. Further studies on photoswitch mechanism is under way.

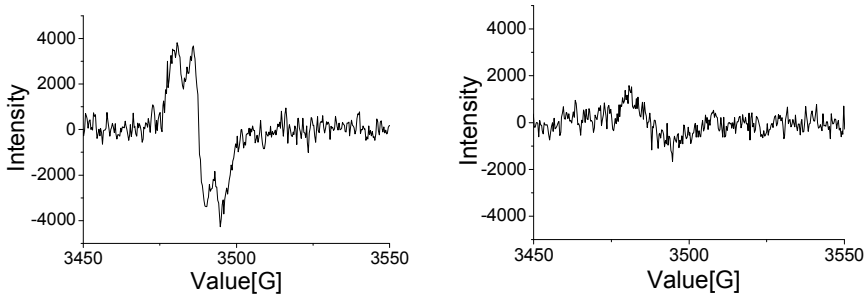

Fig. 4 ESR spectra of the mixture of compound 1 (0.01 M) and lanthanum nitrates (0.1 M) irradiated by 355 nm UV light (left) and then by 532 nm visible light (right).

Conclusion

In conclusion, the spectroscopic behavior of the supramolecular system containing photochromic calixarene derivatives and lanthanum ions can be regulated by light with remarkable changes in absorption spectra , emission spectra and ESR spectra. These photoswitchable changes may be as *on-off* switches in optical sensors and switches.

Keywords: photodegradation, MO, solar irradiation, TiO_2

Abstract: use the sol-thermal method to synthesis nanoparticle TiO2 which is well developed, small diameter and good dispersion. XRD and BET methods were used to analyze the crystal structure and specific surface area. Under nature solar light, the photodegradation activity of TiO_2 is tested. The results show that the TiO_2 sample displayed better photodegradation activity than P25 under solar irradiation.

Introduction

Water pollution is one of the most urgent questions in our daily life [1]. Azo dyes which contain nitrogen to nitrogen double bonds (-N=N-) and carbon to carbon double bonds (-C=C-)) constitutes a significant portion that are widely used in industries today [2]. From last decade, there are many methods under research to solve this problem, such as chemical method, physical method, adsorption and biological methods [3-5]. But all the methods did not work as well as people expected. Since 1972, Fujishima and Honda [6] found TiO_2 can split water into H_2 and O_2 in their research, the TiO_2 semiconductor has attracted extensive attention. As we all known, TiO_2 is very stable, easy to obtain, non-toxic and high photocatalytic[7-10], so TiO_2 semiconductor is considered as the most promising photocatalyst in the future, and its application is wider as the researches are being done. Photodegradation of dyes with solar light can make it an economically viable process since solar energy is an abundant natural energy source. So taken the reality, the solar light is a good choice.

In this work, we choose methyl orange (MO) as pollutant. MO is an orange-colored anionic dye with λ max at 464 nm. MO has various harmful effects on human beings: it may cause eye or skin irritation, or inhalation, it may cause gastrointestinal irritation with nausea, vomiting, and diarrhea[11]. We use nanoparticle TiO_2 synthesized by sol-hydrothermal method as photocatalyst to decompose MO with solar light. And the catalyst exhibit high photocatalytic activity than P25.

2. Experiment

2.1. Sample preparation

A given quantity of ethylene glycol (EG) and citric acid (CA) was dissolved under vigorous stirring at 80℃. Then about 1.5mL $Ti(OC_4H_9)_4$ solution and 25mL water was added dropwise under a vigorous stirring to the solution. Stired until a transparent solution was obtained. Then the transparent solution was directly loaded in an autoclave for hydrothermal reaction and kept at 200℃ for 10h. After the hydrothermal treatment, the precipitates were separated from the solution by centrifugation, washed with distilled water and anhydrous alcohol, and then dried in an oven at 60℃.

All the chemical materials are analytically pure grade and used without further purification

The obtained samples were analyzed with an X' Pert Pro MPD diffractometer using Cu (Kα1/Kα2) radiation. The XRD patterns were recorded in a diffraction angle range from 20° to 80°.

The specific surface area was determined by nitrogen adsorption method (Ommishop 100CX, BECKMAN COULTER).

2.2. Photocatalytic degradation of MO

The experiments of photodegradation were carried out outdoors under direct solar light. In a typical experiment [12-13], before irradiation, the glass vessels containing 30ml MO and some quantity as prepared samples were put in the dark 30 minutes to obtain the absorption-desorption equilibrium between the dye and photocatalyst. After that, those reactors were put outdoors (GPS coordinates=31.9, E=117.2) to react.

3. Results and discussion

3.1. Crystalline structure and morphological characterization

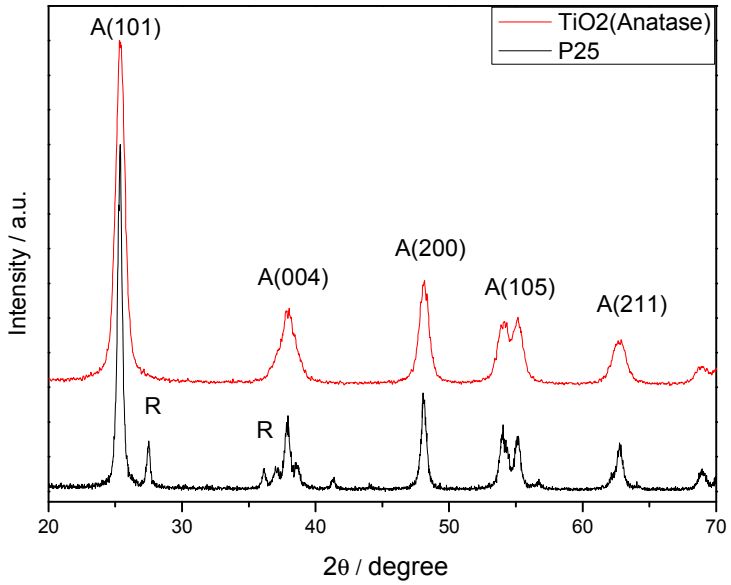

Fig 1: X-ray diffraction patterns of TiO_2 sample and TiO2 P25

As shown in figure 1, TiO_2 samples synthesized by the sol-hydrothermal method is highly crystallized and all the X-ray diffraction peaks correspond to characteristic peak of crystal plane of anatase which shows that the TiO2 sample is pure anatase phase. The peaks of 27.6 and 36.2 show that the commercial TiO2 is composed by anatase phase and rutile phase.

After BET analysis we get the specific surface area (S_{BET}) of TiO_2 sample and P25 are 225.2 and 41.7m^2/g. The S_{BET} of TiO_2 sample is more than 5 times larger than that of commercial P25.

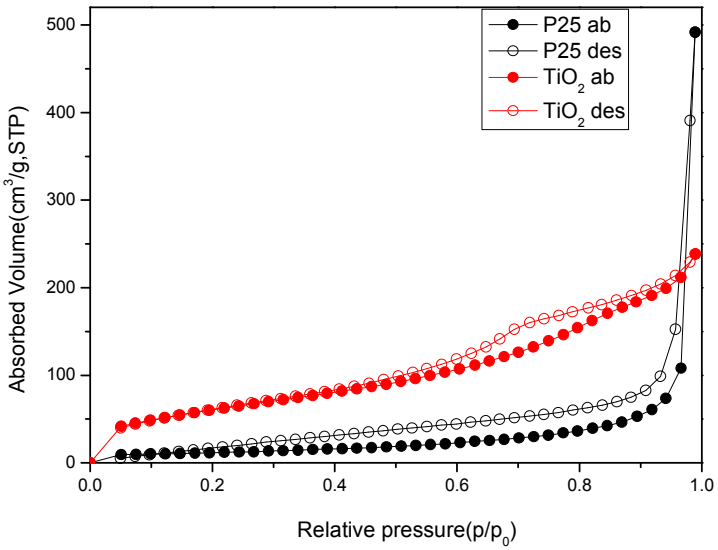

Fig 2: Nitrogen adsorption and desorption isotherms of TiO_2 samples and P25

3.2. photodegradation of MO

The photodegradation efficiency of MO was evaluated according to the percentage

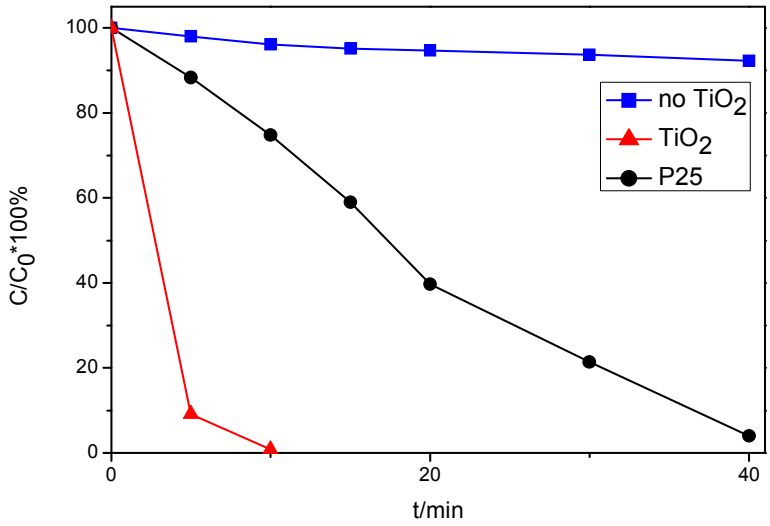

Fig3: The photodegradation of MO by no sample, TiO_2 sample and P25 (C_0=24mg/L,C_{P25}=1.4g/L,C_{TiO2}=1.4g/L）

degradation of MO solution. Figure 3 show the photodegradation of MO using different catalyst. When no catalyst is added, after 40 min irradiation under solar light the decomposition of MO is very little and can be negligible. However, about 99% is decomposed with the TiO_2 catalyst in ten minutes under sunlight. Compared to TiO_2 sample, the commercial P25 can only photo decompose 95% by a long time irradiatio.

4. Conclusion

In this work, we successfully photodegradated MO through a high efficient photocatalyst TiO_2 synthesized by sol-hydrothermal method. Through XRD and BET analysis, the photocatalyst is pure anatase phase, about 10nm and has a very high specific surface area 225.2m^2/g. Under solar light irradiation, TiO_2 can completely photo decompose MO in ten minutes, about five times higher than that of P25. In conclusion, the TiO_2 sample is a high effective photocatalyst that can be used for future industrial pollution applications.

Preparation of visible-light active Mn-doped TiO_2 photocatalyst and its photodegradation of methylene blue from solution

Yin Chen [a], Xiaojun Ma [b]

Tianjin University of Science & Technology, Tianjin 300222, China

[a]chenyin880828@163.com, [b] mxj75@tust.edu.cn

Keywords: Mn-doped TiO_2, sol-gel method, methylene blue, photodegradation.

Abstract. Mn-doped TiO_2 nanocrystal photocatalysts were prepared by the sol-gel method using $MnSO_4 \cdot H_2O$ as manganese source. The catalysts were characterized by XRD, SEM, EPR, UV-Vis, their photocatalytic activity for methylene blue (MB) degradation was investigated. The results showed that Mn was doped into the crystal lattice of TiO_2, and had no influence on TiO_2 crystal structure; the size of TiO_2 nanoparticle gradually decreased with Mn doping concentration increasing. The Mn-doped TiO_2 catalysts have enhanced absorption in the visible light region, and its visible light absorptivity increased with Mn doping concentration increasing. The UV-Vis showed the Mn-doped TiO_2 showed higher photocatalytic activity than the undoped TiO_2 for methylene blue degradation under visible light irradiation. It is also found that the MB photodegradation rate of Mn-doped TiO_2 improved by 46% than that of the undoped TiO_2.

Introduction

Since the 1970s when Fujishima, a Japanese scholar, discovered that TiO_2 electric light can be used in water catalytic decomposition, the nanometer TiO_2 has been widely applied in air purification and sewage disposal owing to its strong photocatalytic activity, stable chemical property, thorough degradation of organic matter, no secondary pollution and non-toxicity [1-3]. However, TiO_2 has relatively wide band gap (anatase 3.2eV, rutile 3.0eV) and narrow absorption spectrum, thus only ultraviolet light with the wave length less than 387.5nm can be absorbed. The visible light which accounts for more than 90% of the sunshine fails to excite its photocatalytic activity, thus limiting the further generalization of TiO_2 photocatalyst [4, 5]. Therefore, it is necessary to place great emphasis on the improving the absorbency of visible light of TiO_2.

To improve the photocatalytic efficiency of TiO_2, researchers have adopted different means to modify nanometer TiO_2 in recent years, such as precious metal deposition, ion doping, compound semiconductor and surface sensitization, among which ion doping of transition metal is an effective method [6]. Esparza et al [7] prepared doping photocatalyst of nanometer Co-TiO_2, Fe-TiO_2, and Mn-TiO_2 through hydrothermal method, and the results show that doping photocatalyst absorbs more light than TiO_2 Degussa P25 and nanometer TiO_2 in visible light region. Abdelaal et al [8] prepared Pd/TiO_2-CS photocatalyst by sol-gel method, which could degrade methylene blue solution effectively in visible light region with the degradation rate up to 99.5%. Khan et al[9] found that TiO_2 doped with V could reduce the band gap of TiO_2 and enlarge the specific surface area, leading to the red shift of TiO_2 spectral absorption threshold. Besides, it could also reduce the recombination velocity of electrons and holes with the methylene blue degrading effectiveness of 5 times higher than that of pure TiO_2.

Therefore, Mn-doped TiO_2 nanocrystal photocatalysts were prepared by the sol-gel method using $MnSO_4 \cdot H_2O$ as manganese source. The catalysts were characterized by using scanning electron microscope (SEM), X-ray diffraction (XRD), ultraviolet–visible-light reflectance (UV-vis) spectroscopy, and electron paramagnetic resonance spectrometer (EPR), their photocatalytic activity for methylene blue (MB) degradation was also investigated under visible light irradiation.

Materials and Methods

Preparation of Samples. Gradually and successively blend $Ti(OC_4H_9)_4$ and $MnSO_4 \cdot H_2O$ (molar ratios of Titanium and Manganese are respectively 1:0, 500:1, 400:1, 300:1, 200:1 and 100:1) of certain quantities into a beaker filled with 90ml of anhydrous ethanol in stirring state, and keep one hour of fast stirring on a magnetic stirring apparatus to get the mixed solution A. According to the ratio that $n(H_2O)$: $n(Mn+Ti)$ =4:1, the mixed solution B can be acquired by dissolving distilled water in 60ml of anhydrous ethanol. Blend solution B slowly into solution A in stirring state and then put it into a water bath kettle of 40°C for a certain time of mechanical stirring. Wash the powder with distilled water and dry the powder in 105°C for one hour. After grinding, put the powder in a vacuum tube furnace and in a heating rate of 5°C/min for three hours and calcine for 3 hours when heat reached to a temperature of 450□. Samples can be acquired after natural cooling. According to molar ratios of Titanium and Manganese, samples are labeled as Ti, Mn/500Ti, Mn/400Ti, Mn/300Ti, Mn/200Ti, Mn/100Ti respectively.

Characterization of Samples. Observe the morphology of photocatalyst samples by FEI NANOSEM 430 scanning electron microscope of thermal field emission. Determine the XRD spectrum of samples by Rigaku D/max2500 powder X-ray diffractometer. With the use of Cu Kα ray, λ=1.5405Å, 40kV of tube voltage, 100mA of tube current, 20-80° of scanning angle 2θ, 8°•min-1 of scanning speed, the average diameter D(nm) of photocatalyst samples can be calculated through Scherrer formula $D=K1\lambda/(\beta 1/2 \cos\theta)$, in which K1 is the crystal shape factor with the value of 0.89, β1/2 is the peak width at half height (rad), and θ is the diffraction angle (°). Use Varian Cary 5000 ultraviolet and visible spectrophotometer made in US to determine the UV-vis spectrum of samples and use Bruker A300 electron paramagnetic resonance spectrometer made in Germany to determine the EPR spectrum of samples, of which the operating frequency is 9.64GHz and the power is 63nW.

Photocatalytic Property Determination of Samples. Dissolve 0.05g of photocatalyst into a certain concentration of methylene blue solution of 100ml, and put it into a homemade photocatalytic reactor away from light for magnetic stirring of 0.5 hour, reaching the adsorption equilibrium for the solution. Expose the solution covered with an optical filter (400-800nm of wavelength) under an energy-saving lamp of 65W with a fixed height. Observe the absorbency of methylene blue solution at maximum absorption peak λ=665nm every two hours. Calculate the decolourization ratio D by formula $D=(A_0-A)/A_0\times100\%$, in which A_0 stands for the initial absorbency and A stands for the absorbency after a certain time of reaction.

Results and Discussion

SEM. With the increase of Mn doping concentration, the sample color changes from white to yellow and deepens gradually. Figure 1 showed the scanning electron microscope of all samples. All samples in the figure are nanometer circular particles. Pure TiO_2 dispersed more evenly with identical particle size and smooth surface and large particle size. With the increase of Mn doping concentration, there were slight coacervations for TiO_2 samples with rough surface and small particle size. It can be inferred that Mn was helpful in reducing TiO_2 particle size, enlarging specific surface area, and providing better adsorption conditions for photocatalytic degradation.

XRD. Figure 2 showed the spectrum of nanometer TiO_2 of different Mn doping concentration. It can be seen from Figure 2 that all samples showed characteristic diffraction peak of anatase crystal face TiO_2 (101), (004), (200), (105), (211), (204), (220), (215)[10] with no rutile, proving that a small amount of Mn will not change the crystal structure of samples. With the increase of Mn doping concentration, the diffraction peak when 2θ=25.3° decreased, showing the deterioration of crystal quality. When the diffraction peak gradually became widen, it showed that grain sizes of the catalyst became smaller, which was in line with test results of scanning electron microscope. This could be due to the fact that Mn mixing into the crystal lattice of TiO_2 and the ionic radius of Mn 0.46Å was smaller than that of Ti. Because of the small doping amount of Mn and equal distribution, diffraction peak of Mn cannot be found beyond the detection peak in this figure.

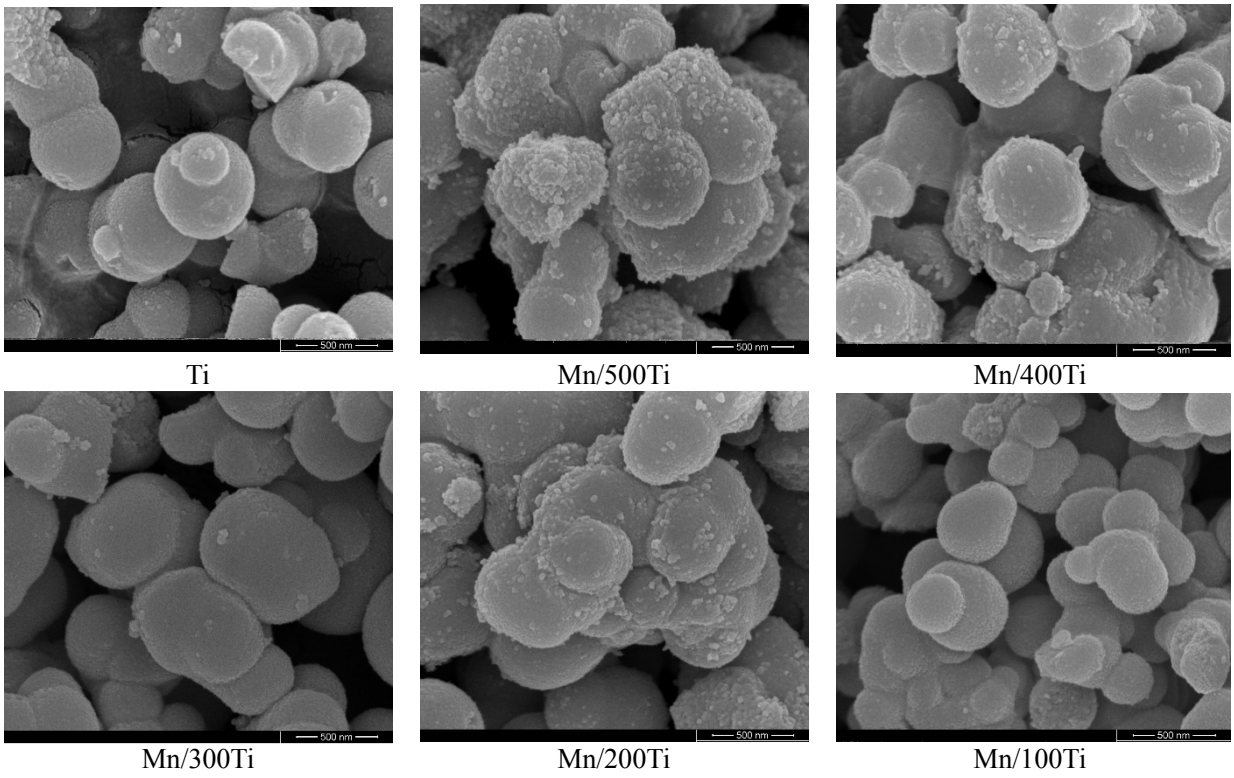

Fig. 1 SEM images of Mn/TiO_2

Table 1 showed average particle sizes of samples calculated by formula Scherrer. The sizes in the table were measured in nanometer. With the increase of Mn doping concentration, particle size decreased, showing that the size of TiO_2 sample could be suppressed by doping Mn.

Table 1. Average sizes of Mn/TiO_2 nanoparticle

Samples	Ti	Mn/500Ti	Mn/400Ti	Mn/300Ti	Mn/200Ti	Mn/100Ti
Average sizes ($D_{(101)}$)/nm	30.20	25.42	23.86	23.13	20.46	19.06

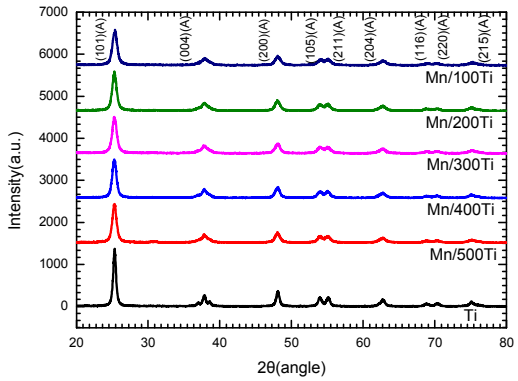

Fig. 2 The XRD spectrum of nanometer TiO_2 of different Mn doping concentration

UV-vis. Figure 3 showed the UV-vis spectral absorption curve of nanometer TiO_2 with different Mn doping concentration. It can be seen that Pure TiO_2 mainly absorbed UV-light with wavelength less than 390nm, the absorption capacity of visible light was relatively poor. This was due to the fact that forbidden band length of anatase type TiO_2 was 3.2eV and visible light energy was not enough to inspire electron hole pairs of photoproduction. The absorption spectrum of TiO_2 samples doped with Mn in visible light region was enlarged, of which the wave band of 390nm-650nm was enlarged the most. This was mainly because Mn^{2+} produced impurity level in forbidden band of TiO_2, reducing the energy electron transition from valence band (VB) to conduction band (CB).

With the increase of Mn doping concentration, the absorption amounts of samples in visible light region were also increased. Absorption spectrums of Mn/400Ti and Mn/300Ti were close to each other due to Mn doping amounts. The content of Mn in samples was quite low and the dispersibility was good, so there was no oxide absorption peak found in this figure.

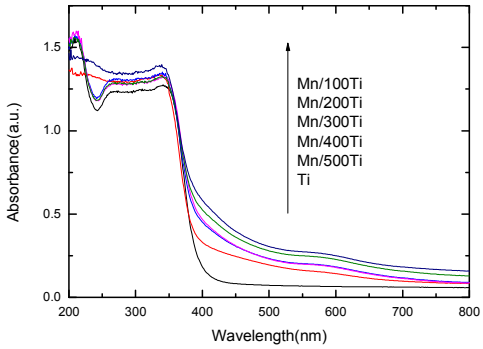

Fig. 3 The UV-vis spectral absorption curve of TiO_2 with different Mn doping concentration

EPR. Nano-powder of TiO_2 doped with Mn is a good diluted magnetic semiconductor, so EPR can be used to analyze the dosage concentration of Mn. In EPR spectrum, Mn has six hyperfine splitting structures, which means that Mn^{2+} replaces Ti^{4+} in crystal lattice, existing on the surface of lattice or forming a cluster of Mn [11]. Figure 4 showed the EPR spectrum of TiO_2 with different Mn doping concentrations. It can be seen that samples of TiO_2 doped with Mn had six hyperfine splitting spectrums, while pure TiO_2 samples had no such phenomenon. Thus, it can be inferred that Mn had successfully blend into the crystal lattice of TiO_2. With the increase of Mn doping concentration, six hyperfine structures became flat due to excess amount of Mn that clustering on crystal surface.

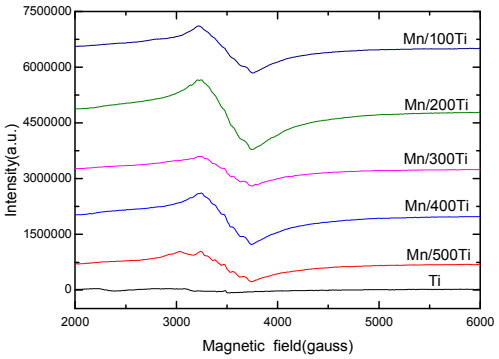

Fig. 4 EPR spectrum of Mn TiO_2

Photodegradation of methylene blue. Figure 5 showed the curve of TiO_2 doped with Mn degrading methylene blue under visible light. Degrading effects of all samples of TiO_2 doped with Mn precede that of pure TiO_2. Compared to pure TiO_2, decolorization rates of samples, including Mn/500Ti, Mn/400Ti, Mn/300Ti, Mn/200Ti and Mn/100Ti increase by 31%, 18%, 15%, 46% and 18% respectively. The decolorization rate of Mn/500Ti is apparently higher than those of Mn/400Ti and Mn/300Ti, because a small amount of Mn can be evenly dispersed in the TiO_2 crystal lattice more easily while a large amount of Mn caused clustering. Decolorization rates of Mn/400Ti and Mn/300Ti were significantly lower than that of Mn/200Ti, which suggested that a moderate amount of Mn improved the visible-light catalytic activity of TiO_2 more easily. This was because Mn could fully fill TiO_2 crystal lattice when its content was increased to a certain extent, making all excited electrons could easily transit to the impurity level provided by Mn. However, the decolorization rate of methylene blue started to decrease when the molar ratio of Mn and Ti reached 1:100, because the accumulation of Mn provided a recombination center for electron hole pairs.

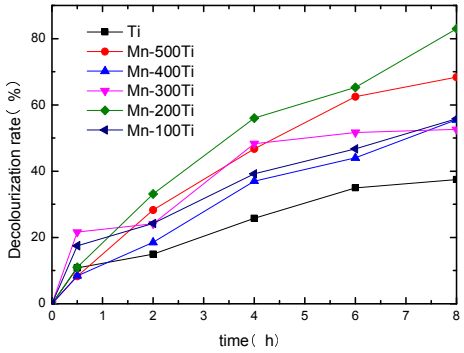

Fig. 5 The curve of TiO_2 doped with Mn degrading methylene blue under visible light

Conclusion

Mn was doped into the crystal lattice of TiO2, and had no influence on TiO2 crystal structure. The growth of particle size of TiO_2 powder was suppressed by doping Mn, and the depressor effect enhanced with the increase of Mn doping concentration. The particle size of TiO_2 ranged from 19nm to 25nm after Mn-doped.

TiO_2 possesses relatively strong absorbency and photocatalytic activity after the doping of Mn. The sample of Mn/200Ti had the best degradation effect of methylene blue under visible light, which is 64% higher than that of unmodified TiO_2.

Keywords: Mild steel ;Weight loss; Polarization; Acid inhibition.

Abstract. The corrosion inhibition of mild steel in 5.0 M HCl by 1–phenylaminomethyl-benzimidazo -le(PMB) was studied by gravimetric and potentiodynamic polarization methods. Inhibition efficiency of PMB increased with increase in the concentration of inhibitor and decreased with the increase in temperature. PMB acts as anodic-type inhibitor for mild steel. The adsorption of PMB on mild steel surface obeys the Langmuir adsorption isotherm.

Introduction

Hydrochloric acid are widely used in various industrial processes such as acid pickling and acidic cleaning , the petrochemical processes, oil well acidification,which generally leads to serious metallic corrosion[1,2]. As the most effective and economic method, inhibitors are applied in the acid solution to control the metal dissolution[3]. Benzimidazole and its derivatives have received considerable attention on their inhibition properties for metallic corrosion over the past years [4,5].

In this paper, the corrosion inhibition performance of 1-phenylaminomethyl-benzimidazole (PMB, Fig. 1) for mild steel in hydrochloric acid solutions was investigated by weight loss and electrochemical techniques.

Experimental details

Materials. Mild steel was used for weight-loss and electrochemical tests. For weight loss tests, the rectangular coupons with the size of 4.0×1.3×0.2 cm were used. The acid solutions used in the work were prepared from analytical grade HCl and deionised water. The concentration of inhibitors was ranged from 0.1 to 2.0 mM.

PMB was synthesized according to the procedure described elsewhere[6]. Reaction equation is shown in figure 1.

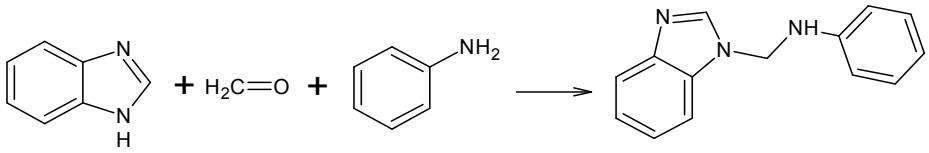

Fig.1. Reaction equation on the inhibitor(PMB)

Weight loss measurements. Weight loss measurements were carried out under total immersion using 250mL capacity beakers containing 200mL test solution without and with different concentrations of inhibitor in 5.0M HCl solutions . The temperature of the solutions was held at 303-333K by a thermostat water bath. After 4 h of immersion in the acid solutions in air without bubbling, the samples were taken out and carefully washed with deionised water and ethanol, and then dried and weighed.

The corrosion rate(v) in g m^{-2} h^{-1} was calculated from the following equation:

$$v = \frac{W_0 - W}{St}$$

where W_0 and W are blank and inhibited mass loss, respectively, S is the area of specimen, and t is the corrosion time.

With the calculated corrosion rate, the inhibition efficiency (η) was calculated as follows:

$$\eta = \frac{v_0 - v}{v_0} \times 100\%$$

where v_0 and v are the corrosion rates of the mild steel coupons in the absence and presence of inhibitor, respectively.

Electrochemical measurements. The classical three-electrode system was used for electrochemical measurements. A platinum electrode and a saturated calomel electrode (SCE) with a Luggin capillary served as counter electrode and reference electrode, respectively. After an hour immersed in the non-de-aerated solutions under unstirred conditions, electrochemical measurements were carried out by CHI660E electrochemical workstation. Potentiodynamic polarization curves were recorded at a sweeping rate of 0.5 mV s^{-1}. The inhibition efficiency, (η), was calculated from the following equation:

$$\eta = \frac{i_{corr} - i_{corr(inh)}}{i_{corr}} \times 100$$

where i_{corr} and $i_{corr(inh)}$ are the corrosion current densities obtained in uninhibited and inhibited solutions, respectively.

Results and discussion

Weight loss measurements. The result of weight loss method was used to evaluate the inhibitive effects of PMB on the corrosion of mild steel. Fig.2 and Fig.3 show the values of corrosion rate and inhibition efficiency in the absence and presence of different PMB concentrations ,respectively.

It is evident from Fig.2 that the corrosion rate of mild steel in 5.0 M HCl increases with temperature but decreases in the presence of PMB. Furthermore, the inhibition efficiency increases with increase in PMB concentration. The inspection of the table further reveals a decreasing trend in inhibition efficiency with increasing experimental temperatures for all the system studied.

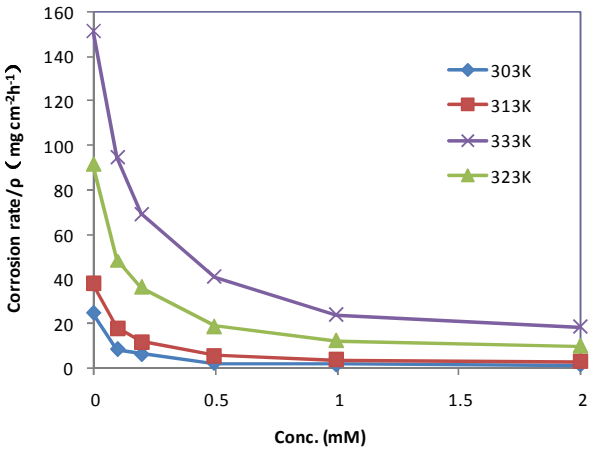

Fig.2 The relationship between corrosion rate and concentration at different temperatures

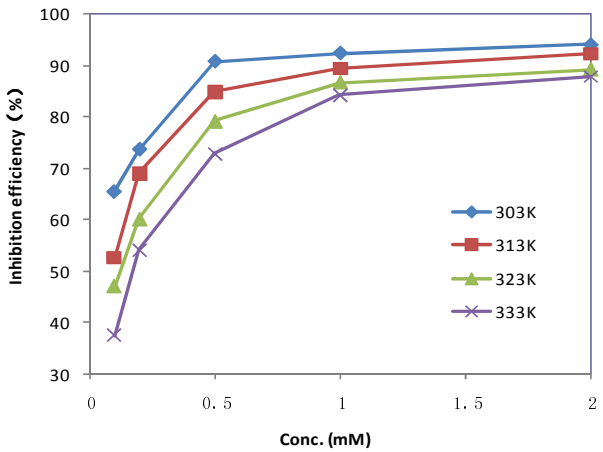

Fig.3 The relationship between inhibition efficiency and concentration at different temperature.

Adsorption and thermodynamic considerations. Since the mechanism of the interaction between inhibitor and the metal surface can explained using adsorption isotherms, a direct relationship between inhibition efficiency (η) and the degree of surface coverage ($\theta = \eta/100$) can be assumed for different concentrations of the inhibitor. Data obtained from weight loss measurements were tested graphically by fitting various adsorption isotherms and kinetic-thermodynamic models including Langmuir, Freundlich, Hill de Boer, Parsons, Frumkin,Temkin, etc. By far, the experimental data for PMB, best fitted the Langmuir isotherm (Fig. 4), with a clarified relationship between C_{inh}/θ *and* C_{inh}. The correlation coefficient R^2 was used to determine the fitting of the

experimental data to this unique isotherm. The isotherm is characterized by the mathematical model given below:

$$\frac{C_{inh}}{\theta} = C_{inh} + \frac{1}{K_{ads}}$$

where K_{ads} denotes the equilibrium constant for the adsorption process.

Fig. 4 shows the plots of C_{inh}/θ versus C_{inh} and the expected linear relationship is obtained for PMB. The strong correlations ($R^2 \geqslant 0.9997$) confirm the validity of this approach. The slopes of the straight lines are 1.0377,1.0438,1.0647,1.0573 at the experimental temperatures(303-333K), suggesting that adsorbed inhibitor molecules form monolayer on the mild steel surface and there is no interaction among the adsorbed inhibitor molecules.

The adsorption parameters derived from the plot are listed in Table 1. The equilibrium constant of adsorption K_{ads} is related to the standard free energy of adsorption ΔG_{ads}, with the following equation:

$$K_{ads} = \frac{1}{55.5}\exp\left(\frac{-\Delta G^{\theta}_{ads}}{RT}\right)$$

The heat of adsorption was evaluated according using the Van't Hoff equation:

$$\ln K_{ads} = -\frac{\Delta H^{\theta}_{ads}}{RT} + \text{constant}$$

where ΔH^{θ}_{ads} and K^{θ}_{ads} are the heat of adsorption and equilibrium constant of adsorption, respectively.

Again another thermodynamic parameter (ΔS^{θ}_{ads}) was calculated by the use of the basic thermodynamic equation:

$$\Delta G_{ads} = \Delta H_{ads} - T\Delta S_{ads}$$

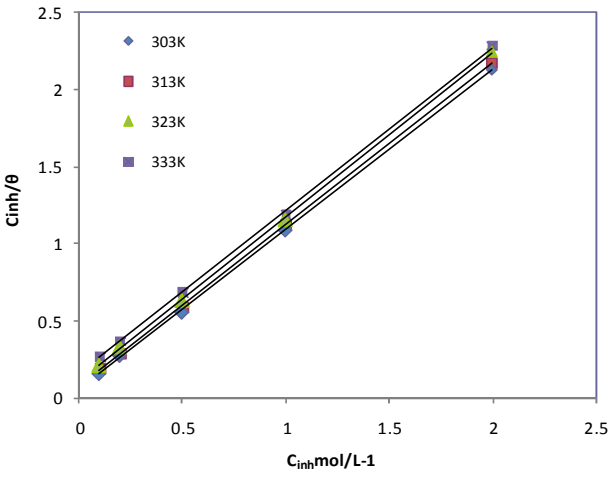

Fig.4 The relationship between C_{inh}/θ and C_{inh} for PMB at different temperatures.

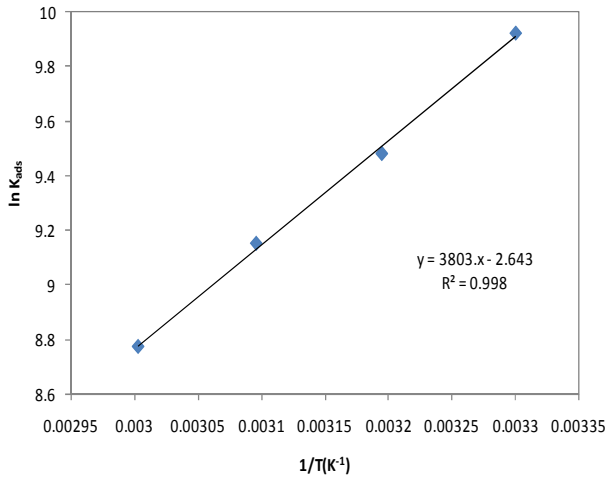

Fig. 5 The relationship between ln Kads and 1/T for PMB

The values of K_{ads} (Table 1) indicate that the binding power of the inhibitor to the metal surface decreases with increasing temperature. Such behavior can be interpreted on the basis that an increase in temperature results in the desorption of some molecules of the PMB from the metal surface. The values of the ΔG_{ads} in all the cases are negative. The negative values signify a spontaneous adsorption of the inhibitor molecules and stability of the adsorption layer. Fig. 5 shows the relationship between $\ln K^{\theta}_{ads}$ and 1/T for PMB and the absorptive heat (ΔH^{θ}_{ads}) was approximated from the slope of the graph under the experimental conditions and presented in Table 1. The negative value of ΔH^{θ}_{ads} (-31.63 kJ mol^{-1}) at all the temperature studies reflect the exothermic nature of the adsorption process of the inhibitor molecules on steel surface. ΔS^{θ}_{ads} values of 11.20 – 11.53 kJ mol^{-1} (Table 1) were obtained by substitution of corresponding values of other thermodynamic values at 303 – 333 K. The positive sign of ΔS^{θ}_{ads} arises from substitutional process, which can be attributed to the increase in the solvent entropy and more positive water desorption entropy. This leads to an increase in disorder due

to the fact that more water molecules can be desorbed from the metal surface by one inhibitor molecule.

Table 1 Thermodynamic parameters of adsorption of PMB on the mild steel surface at different temperatures.

T(K)	K^{θ}_{ads}(M^{-1})	R^2	ΔG^{θ}_{ads}(kJ mol^{-1})	ΔH^{θ}_{ads}(kJ mol^{-1})	ΔS^{θ}_{ads}(kJ mol^{-1})
303	20358.31	0.9997	-35.11	-31.63	11.53
313	13107.88	0.9998	-35.13	-31.63	11.20
323	9434.85	0.9999	-35.37	-31.63	11.59
333	6469.56	0.9997	-35.42	-31.63	11.38

Potentiodynamic polarization measurements. Table 2 shows the electrochemical corrosion parameters such as corrosion potential (E_{corr} versus SCE), corrosion current density (i_{corr}), cathodic and anodic Tafel slopes (ba, bc). From Table 2,when the concentrations of PMB are increased, the values of corrosion current density decrease sharply associated with the increase in the inhibition efficiency, which indicates that the presence of inhibitor lowers the corrosion rate considerably.In adition, the presence of PMB in the acidic solution results in a slight shift of corrosion potential towards more negative in comparison to that in its absence, therefore PMB can be considered basically as an cathodic inhibitor.

Table 2 Potentiodynamic polarization parameters for the corrosion of mild steel in 5.0M HCl without and with different concentrations of PMB at 308K.

Conc.	E_{corr}(mv)	i_{corr}(μA/cm^2)	b_a(mV/dec)	bc(mV/dec)	η/%
blank	-383	713.40	20.24	-11.93	-
0.2mM	-395	160.90	58.56	-32.47	77.4
1.0mM	-388	83.93	89.57	-58.72	88.2
2.0mM	-388	70.30	102.91	-65.59	90.1

Conclusion

Based on the results of investigation, the following conclusions are drawn:

1. PMB acts as a good inhibitor for the corrosion of steel in 5.0M HCl. The inhibition efficiency increases with the increase in inhibitor concentration but decreases with the increase in temperature.
2. The adsorption of PMB obeys the Langmuir adsorption isotherm.
3. Values of standard enthalpy of adsorption and standard free energy of adsorption indicate that the adsorption of PMB on the surface of mild steel involves both physical and chemical processes.
4. PMB acts as cathodic inhibitor by inhibiting the cathodic reactions.

Keywords: Nano-sized magnesium hydroxide; Concentrated seawater; Brine; Preparation

Abstract: The nano-sized magnesium hydroxide is a valuable intermediate for chemical industry materials. This review covers the preparation methods of nano-sized magnesium hydroxide using concentrated seawater or brine as raw material, including alkaline method, calcium method, ammonia method and other new methods. Additionally, the development trend of preparing nano-sized magnesium hydroxide from concentrated seawater or brine was analyzed.

1 Introduction

Nano-sized magnesium hydroxide is one of the important chemical materials and intermediates, which can be used as waste water neutralization agent, flue gas desulfurization agent, food preservation additives, etc [1]. In particular, it appears to have a special flame retardant properties when filled into polymer materials such as rubber, plastic and resin. In the use and disposal process, it is an extremely promising environment-friendly green flame retardant without any harmful substances emissions [2-3].

Magnesium resources is rich in China, in addition to the salt lake brine, brine wells mine, underground brine and other natural liquids mineral resources, seawater desalination, sea salt production, salt lake potassium and other industries also produce thousands of tons seawater and brine a year, which contain rich magnesium ions[4]. The development of magnesium resources in China mainly concentrated in the low value-added products such as magnesium sulfur, magnesium chloride, magnesium fertilizer, or in the form of ore direct export, which caused great waste of resources. Developed nano-sized magnesium hydroxide products with high added value is in the more and more important position [5-6].

2 Technology experimental study

The magnesium hydroxide can be prepared by variours routes. Typically by mixing concentrated seawater or brine with basic compounds such as sodium hydroxide, calcium hydroxide or ammonia. And the nano-sized magnesium hydroxide products can be obtained by controlling the reaction time, temperature, magnesium ion concentration as well as the pH value, etc. There are three kinds of methods commonly used: alkaline method, calcium method and ammonia method.

2.1 Alkaline method

Alkaline method uses sodium hydroxide as precipitation agent, the purity of sodium hydroxide is higher, so it is not easy to introduce impurities and the morphology, particle size distribution and crystal structure of the products are easy to control, which is suitable for the preparation of high purity product [7]. Wu et al. [8] used Zhanjiang coastal waters as raw material, sodium hydroxide as a precipitating agent, by adding glycol in water thermal system, and controlling the reaction

temperature at 170 ℃, reaction time with 4 h, received a good dispersion, crystalline regular, high purity magnesium hydroxide nanoparticles. Ma et al. [9] used concentrated seawater after desalination as raw material, after calcium removal, precipitation, ceramic membrane separation washing, centrifugal filtration and vacuum drying processes, the high purity nano-sized magnesium hydroxide was obtained. The product quality was better than chemical industrial standard (magnesia content is 67.9% , calcium oxide content is 0.2%) and the average diameter was below 100 nm. Ren et al. [10] used Tianjin Hangu potassium salt preparation mother liquor as raw materia to prepare nano-sized magnesium hydroxide. Different hydrothermal treatment methods, including hydrothermal treatment at low temperature, at high temperature, in magnesium hydroxide solution and hydrothermal treatment after seeding as well, were used to treat the magnesium hydroxide powder. The studies showed that the method of hydrothermal treatment after seeding could easily be used into industry production.

2.2 Calcium method

Calcium method uses calcium hydroxide (usually in the style of limestone or dolomite) as precipitation agent. The advantage of calcium method is the low cost of raw material, but the complex process and large energy consumption cannot ignore in calcination and digestion. Moreover the insoluble impurities in raw materials and impurities produced from the reaction are difficult to be removed, which has a bad effect on the product purity[11]. Han et al. [12] taked the natural brine from salt lakes as raw material, lime milk as precipitator, controlled the temperature at 40～90 ℃ and adopted special calcium-removing technique to obtain magnesium hydroxide with the mean particle size about 80 nm. The quality of the product reaches the national standard, the $Mg(OH)_2$ content of the product was more than 98% , the CaO content was less than 0.2%. In addition, Zhao et al.[13] introduced PLC automatic control system for controlling the reaction time, temperature, the magnesium ion initial concentration in the solution, alkaline solution dropping speed as well as the pH value to the nano-sized magnesium hydroxide preparation, and discussed the considerable economic benefits of using concentrated seawater after desalination to prepare nano-sized magnesium hydroxide.

2.3 Ammonia method

Ammonia method uses ammonia as precipitation agent, the magnesium hydroxide crystallization performance used ammonia method is normally better than calcium method and alkaline method. As ammonia is a weak base, the pH is about 10 and the solution has a buffer action after the reaction completion. In addition, the mother liquor can be reused at the same time: the compound fertilizer containing N, P, K, Mg and B can concentrated prepared, in the other way, the ammonia can collected and reused when adding lime milk into[14]. Zheng et al. [15] studied the pH value, magnesium ion concentration, ammonia dropping rate, temperature, the amount of dispersant and other factors on the preparation of nano-sized magnesium hydroxide on the basis of ammonia method, and proposed optimum prepared conditions: the pH of ammonia is 14; the concentration of $MgCl_2$ is 0.5 mol/L; the rate of adding ammonia is 2.0 ml /min; the reaction temperature is 50℃-60℃ and the reaction time is 60 min. It was also found, along with ammonia added in the system, the pH value was gradually increased, first appeared translucent gel precipitated, and finally formed a stable gel precipitation, the longer the gel suspension time, the slower sedimentation rate is. When the solvent containing ethanol, the formation of precipitation sedimentation is fast, the right amount of alcohol can inhibit the precipitation cementation and crystal growth in one direction, which can also overcome the reunion of powders. Wang et al. [16] used Jilantai Salt Lake Brine as magnesium source, took the optimum conditions to prepare a polygonal sheet nano-sized magnesium hydroxide powder, the product was with good dispersion and the average particle size is 89.5 nm. The preparation process is divided into four steps：the magnesium cement preparation, acid leaching of magnesium, acid extract purification and powder preparation. Studies show that the most suitable acid infusion pH is 7.0-7.5, while small

amount of ethanol can promote the precipitation of calcium sulfate, at the same time facilitate magnesium hydroxide dispersion, and PEG200 dispersant can effectively prevent agglomeration of the magnesium hydroxide particles.

2.4 Other methods

Using the traditional methods of preparing nano-sized magnesium hydroxide, the main question is difficult to remove impurity ions, and the product size distribution was wide and the dispersion was poor. Many scholars try to adopt new method to prepare nano-sized magnesium hydroxide. Feng et al. [17] used a strong base anion resin in the experiment, prepared nano-sized magnesium hydroxide by ion exchange method. The product is with hexagonal sheet structure and with good dispersion, the particles average size is about 100 nm. The impurity ions can be replacement to the resin using this method, successfully solved the impurity ion elution difficult problem. Lu et al. [18] used the "sulfur hydride - hydrothermal method" to prepare nano-sized magnesium hydroxide, and the product was with larger particle size and better filtration performance. But its irregular morphology and significantly aggregation can not be ignored, and the reaction process was with poisonous gas H_2S released, when futher reclaimed the tail gas, the cost corresponding increased together. According to this method, Jin et al. [19] studied the effects of particle morphology on product properties. The result was that the faster the heating rate and the lower the $MgCl_2$ initial concentration, the smaller magnesium hydroxide particles formed, the easier it is hydrothermal modification, which is good for forming rule morphology and good dispersion nano-sized magnesium hydroxide.

3 Development trend

The concentrated seawater and brine resources is rich in China, only the Saline Lake brine magnesium salt reserves amounted to 48.16 tons. But this resources utilization rate is not high. Extracting magnesium salt from concentrated seawater or brine, especially those with high value-added nano-sized magnesium hydroxide is of great significance. According to the gap with developed countries in the product quality and also manufacturing scale, to strengthen the production and application study of nano-sized magnesium hydroxide is imminent:

1. To improve nano-sized magnesium hydroxide morphology control, especially in special morphology and particle size distribution. High quality nano-sized magnesium hydroxide products is significative to improve the international competitiveness.
2. To suppress aggregation of nano-sized magnesium hydroxide in the production process. To speed up the study of surface modification, recognizing modification mechanism, constantly trying new modification methods, especially to develop the nano-sized magnesium hydroxide exclusive modifier, is the focus of nano-sized magnesium hydroxide material in application.
3. To make the full use of concentrated seawater or brine to prepare nano-sized magnesium hydroxide . The low cost and high concentration make it a good raw material, which could reduce the production cost, meanwhile, the reuse of concentrated seawater and brine is meaningful for the environment.

Abstract : In this paper, the Back-Propagation neural network (BP network) and the establishment of the AZ61 magnesium alloy high temperature constitutive model and test data obtained for training the neural network, after training the neural network to become a knowledge-based constitutive model formed AZ61 magnesium alloy flow stress and dynamic recrystallization of the neural network model tested by the neural network model with traditional regression methods predict contrast, results showed that the higher the accuracy of the neural network model for dealing with a large number of test data to establish the constitutive relations of materials with high stress and promotion of value.

1 **Introduction**

Magnesium alloy for its lightweight characteristics, in recent years in the automotive, aerospace, electronics industry gained rapid development, showing broad application prospects. Because the crystal structure of the magnesium alloy is hexagonal, plastic forming ability, the development and application of wrought magnesium alloys in order to keep its hot forming process, in order to improve the yield and product performance, you need to master the system wrought magnesium alloys during hot deformation the flow behavior and organizational evolution. Physical modeling and numerical simulation is now usually magnesium alloy used SPSS regression analysis, the model created by the accuracy of the method is not high, the error is larger, the need to search for more accurate mathematical model of high-temperature flow stress. In this paper, Back-Propagation neural network (referred to as the BP network) to establish AZ61 magnesium alloy high temperature constitutive model, using experimental data obtained for neural network training, after training the neural network will become a knowledge-based relationship model through the neural network model to predict the test compared with the traditional SPSS regression analysis to verify its feasibility.

2 Test

From the diameter of 200 mm semi-continuous casting made of magnesium alloy taken the same position as the sample size number Φ10mm × 15 mm, the nominal chemical composition of the material is: 6% Al, 1% Zn, 0.3% Mn, the balance being Mg and trace impurities. After 400 ℃ × 12 h homogenization treatment, performed on Gleebl-1500D thermal simulation test machine direction isothermal heat constant speed uniaxial compression tests, before deformation heating heating rate of 2 ℃ / s, thermal insulation 2min. Compression technology for the 16 combinations of temperature and strain rate deformation: the deformation temperature was 300 ℃, 350 ℃, 400 ℃ and 450 ℃, strain rates were 0.01s-1, 0.1s-1, 1s-1 and 5s-1.

3 neural network model

3.1 Sample Data Organization

Magnesium alloys in high temperature deformation, deformation strain hardening is balanced by dynamic softening process, so we had a large degree of deformation in the flow stress remained stable phenomenon. Due to the impact of dynamic softening process, the relationship between the

flow stress and dynamic material recrystallized grain size and deformation temperature, strain rate and extent of deformation of a complex nonlinear. In this paper, the artificial neural network approach to build its high-temperature flow stress and dynamic recrystallization mathematical model size, the deformation temperature and strain rate is set to enter the amount of the network, the flow stress and recrystallized grain size to the network output amount, before training network, the first group of 16 test samples obtained data were normalized so that all data between the property of a 0-1, and the network output value by anti-normalization after that obtain the original data of physical space. Normalization method derived from Formula 1[1]:

$$d = \frac{d - d_{\min}}{d_{\max} - d_{\min}} \quad (1)$$

In the formula, $d_{\min}$ and $d_{\max}$ are respectively the minimum and maximum values for the sample data.

3.2 neural network structure determination

Number of neurons in the hidden layer of BP network training accuracy and convergence speed of neural network training process has a great impact, you need to be determined by trial and error. As used herein, the neural network back-propagation network (BP network), the network consists of three layers: an input layer, middle, layer (hidden layer) and output layer. The input layer has two nodes, respectively, deformation temperature and strain rate, the output layer also has two nodes, representing the recrystallized grain size and flow stress.

Literature[2] indicates that, the geometric mean can be used to select the processing unit the number of rules to the intermediate layer. For the three networks, where the number of nerve cells between the hidden layer is selected by the following formula:

$$h = \sqrt{m \cdot n} + \alpha \quad (2)$$

$$h \geq \frac{N \cdot m}{n + m} \quad (3)$$

In the formula, h is the number of units in the hidden layer, m is the number of units of the input layer, n is the output layer unit, N is the learning capacity of the sample, α is a constant. Among α may be equal to 0[3], that constant can take between 0-10[4].

From the middle layer of the test cell count less paper h_0 = 6, select the appropriate criteria to detect and evaluate training, network; If the network reaches a predetermined performance requirements, you can determine the number of units in the middle layer, an intermediate layer unit otherwise increase number is $h_{i+1} = h_i + 1$,Then use the same criteria to detect and evaluate training , network. In this paper, the middle layer to find the optimal number of cells in the process, using BP network training algorithm ordained decline, according to the literature shows that α=0.6~0.95，η=0.45~0.90[5-6]，Getting the optimal number of units after the middle layer, Changing the learning rate of the system X and Momentum coefficient Y to determine their optimal values. $\eta = 0.45, 0.50, 0.55, 0.60,$ and $\alpha = 0.60, 0.65, 0.70, 0.75, 0.80, 0.85, 0.90, 0.95,$ Training, examine and evaluate network, In order to get the best learning rate η and momentum coefficient α.

4 neural network test results

In the middle layer of cells to find the optimal number of training, when the intermediate layer unit is 7 or more, the network oscillations in the initial stages of training, and with the increase in the number of units of the oscillation and intensified, but the number of units in the middle layer of when 7-9, the initial training as training progresses oscillations gradually stabilize and eventually converge to a small error. After the increase in the number of cells in the middle layer, network with fewer steps training can converge to a certain error range. As the network prediction performance

than training time, mainly on the middle layer after several different units, predict the performance of the network to determine the optimal number of cells in the middle layer. According to the results of the training, the number of units when the intermediate layer 11, the network showed a more excellent performance, so the establishment of BP neural network model 2-11-2. The algorithm selection of additional momentum method, the key parameters back-propagation algorithm is a constant learning rate and momentum coefficient. Under the pilot program parameters considered, network performance can get better training, network training error that little difference. Compared to predict the effect of training and its effect in terms of a bit weak, but overall, the results are good. And when momentum coefficient increases when training oscillations occur in the initial stages and has exacerbated the phenomenon, but in training to 100 steps up 200 steps, the network will be stabilized. Occasionally, the network is slow decrease, but in most cases, the network decreased rapidly. Figure 1 is the flow stress and the prediction error image training error. Figure 2 is the recrystallized grain size and the prediction error image training error.

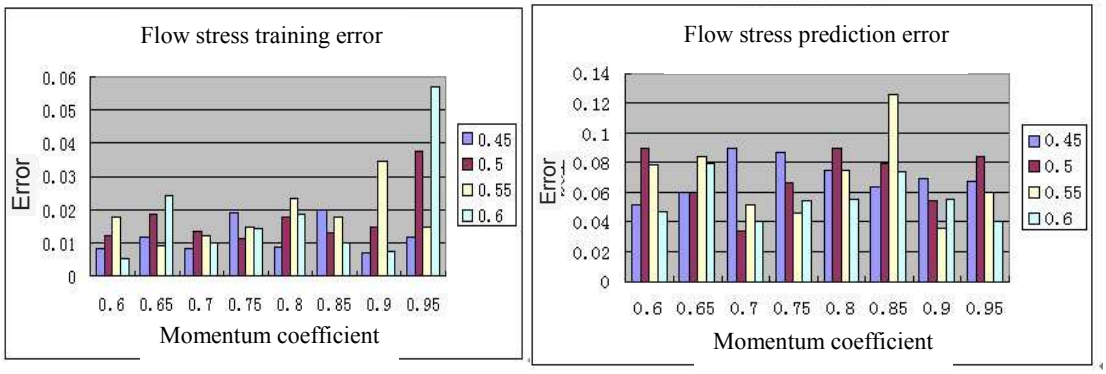

Fig1 The flow stress of the training error and prediction error map

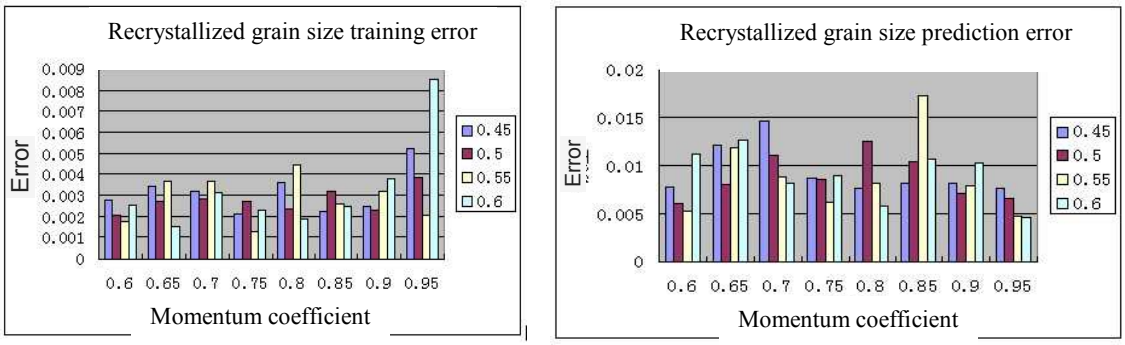

Fig2 Recrystallized grain size of the training error and prediction error in Figure

Comprehensive analysis of the above data can be obtained: flow stress optimal neural network model is the momentum coefficient of 0.7, the learning rate of 0.5 model. You can get the training error is less than 1.5%, forecast error is less than 3.5%; recrystallized grain size of the optimal neural network model is the momentum coefficient of 0.95, learning rate of 0.55 model. You can get the training error is less than 0.2%, forecast error is less than 0.5%.

5 Conclusions

In this paper, Back-Propagation neural network (referred to as the BP network) to establish a high-temperature constitutive model AZ61 magnesium alloy, and use the data obtained in the test for neural network training, after training the neural network to become a knowledge-based constitutive relational model, the formation of AZ61 magnesium alloy flow stress and dynamic recrystallization neural network model, compared with the traditional test to predict regression method by which the neural network model, the results show that the neural network model can accurately predict the AZ61 magnesium alloy Flow stress and dynamic recrystallization grain size changes with deformation temperature and strain rate. The predicted and measured results agree

higher accuracy than the traditional regression methods. Showed its ability to partially replace the test with. This not only greatly reduces the required tests to characterize the flow behavior of the material, but also to avoid the experience of many of the constitutive model constants to determine the problem. The model for processing large amounts of test data to establish the material constitutive relationship with high stress and promotional value.

Keywords: Magnesium alloy, Finite element, Simulation, Forecast

Abstract: In this paper, rigid-plastic finite element simulation software Marc / Auto-forge reflect compression AZ61B magnesium alloy case. Simulation results show that the stress, strain and temperature distribution within the sample is uneven, uneven distribution affect the organization, and with the changes in the deformation process and calculation results with the experimental data exactly. The finite element method can be used in the actual production forecast after tissue deformation components, optimization of process parameters to control the quality of the finished piece.

1 Introduction

Metal temperature of various parts of the work piece and tooling, different stress during hot deformation, and microstructural evolution during deformation is closely associated with these factors. Based on the basic theory of rigid-plastic finite element, finite element simulation software Marc / Auto-forge, AZ61 magnesium alloy thermal compression process further simulation and analysis, analysis of thermal deformation of AZ61 magnesium alloy, and the evolution of the microstructure results were forecasts.

2 Sample finite element model

Cylindrical sample is Φ15 × 20mm, and to reduce the computation time, the symmetry of the sample, take half as analog objects. Take a four-node quadrilateral element model of division 48 units and 65 nodes. Analysis method using an updated Lagrange method described thermal coupling large deformation rigid-plastic finite element method, the use of the material yield criterion Von Mises criterion.

Boundary conditions:

(1) boundary conditions: all nodes cylindrical symmetry axis of the sample in the x-direction displacement is zero, ux = 0.

(2) friction conditions: between deformation tools and rolling contact surfaces follow Coulomb friction coefficient between the die and the sample taken 0.2.

(3) heat transfer boundary conditions[1]: the presence of the free surface of the sample and the cycle of convective and radiative heat transfer environment. There is no contact between the sample heat when in contact with the mold. The first two boundary conditions referred to in the third boundary condition in heat transfer. Can be written as a unified formula:

$$q = -\lambda\left[\frac{\partial t}{\partial n}\right] = \alpha\left(t - t_{\infty}\right)$$

In the formula, t is the surface temperature, t_{∞} is the ambient temperature, α is the heat transfer coefficient.

Convective heat transfer coefficient environment take 0.17KW/m2 • K according to test conditions. And radiation heat transfer coefficient between the environment in accordance with the laws of the radiation is converted into other small radiation heat transfer coefficient can be expressed by the following formula based on radiation law[2-3].

$$h_r = \sigma\varepsilon\left(t + t_\infty\right)\left(t^2 + t_\infty{}^2\right)$$

In the formula, σ is the Boltzmann constant, σ = 5.67 × 10-11KW/m2K4, ε thermal emissivity material, 0.15[4].

Thermal contact between the sample and mold simplified contact heat conduction problems with the contact between the two solid thermal conductivity, paper = 20 KW/m2 • K. Ambient temperature and mold temperature, and were taken 20 ℃ 350 ℃. The thermal deformation of metal deformation, thermal power conversion factor of 0.9. Further, the sample contacting surface and the mold will produce frictional heat, the heat is distributed evenly to the parts of the specimen and the mold[5-6].

3 Simulation results and analysis

3.1 Equivalent strain distribution

Figure 1 is a sample of AZ61 magnesium alloy at different deformation temperature equivalent strain distribution. Be seen, the equivalent strain of the sample is very uneven in the top of the sample, due to friction, the minimum strain, and the sample portion and the corner portion of a sample core greatly deformed. Other parts of the deformation distribution be between the maximum and minimum by the Ministry to the top of the heart, the center to the edge showed a decreasing trend. Can also be seen from Figure 1, as the temperature increases, the deformation easily throughout the strain increases at a lower temperature (300 ℃ to 400 ℃) increase in the amount of more instructions corresponding to the temperature variables influenced; but at around 450 ℃, 400 ℃ to reduce the amount of increase, indicating less affected by temperature corresponding variables.

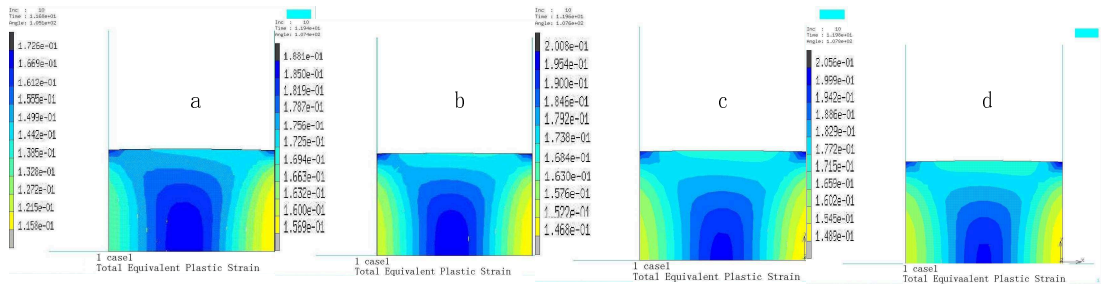

Fig.1 Equivalent strain distribution during the deformation step 10
(a: deformation temperature 300 ℃, strain rate of 0.01s^{-1}; b: deformation temperature 350 ℃, strain rate of 0.01s^{-1}; c: deformation temperature 400 ℃, strain rate 0.01s^{-1}; d: deformation temperature 450 ℃, strain rate 0.01s^{-1})

3.2 Equivalent stress distribution

Figure 2 is the effective stress variation with temperature distribution seen from the figure, the force effect of the sample and a very uniform, the top of the sample, due to friction, the minimum strain, and the sample and the sample angle core section deformed great. Other parts of the distribution between the maximum and minimum distortion between the central portion by the top edge portion to the central portion showed a decreasing trend with increasing temperature, easily deformed, the entire stress increases, but the increase in the amount of not more than , indicating little effect of temperature on the strain.

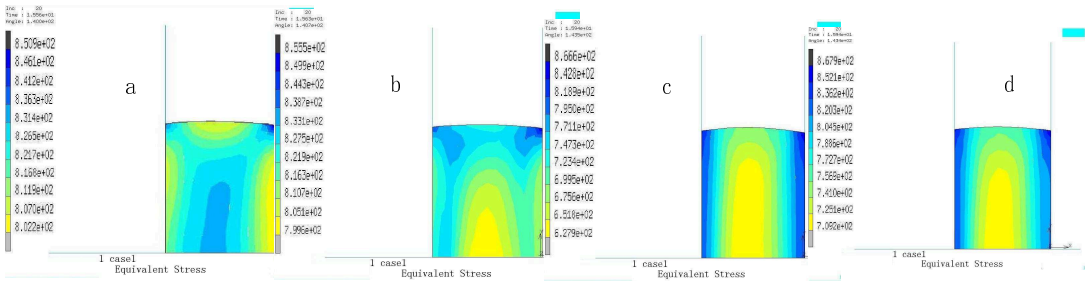

Fig.2 Mises stress distribution of deformation at Step 20

(a: deformation temperature 300 ℃, strain rate of 0.01s^{-1}; b: deformation temperature 350 ℃, strain rate of 0.01s^{-1}; c: deformation temperature 400 ℃, strain rate 0.01s^{-1}; d: deformation temperature 450 ℃, strain rate 0.01s^{-1})

3.3 Temperature distribution

Figure 3 shows the temperature distribution at different strain rates throughout the sample. Since the thermal conductivity of the sample surface exists between the presence of convection and radiation heat, top of the sample and mold, so the temperature decreases from the inside and outside. At low strain rate, prolonged heat and thermal conductivity, high temperature deformation rate when compared to low. Further, the deformation rate increases, an increase in the plastic work, the conversion of heat also increased, thereby increasing the temperature of the sample. Deformation rate of 0.01s-1, the internal temperature of the sample is less than the deformation temperature, when the strain rate 0.1s-1, the temperature of the sample over the central portion deformation temperature. In another modification of the same condition, the amount of deformation increases, the time required to deform at low extension, thus lower the sample temperature.

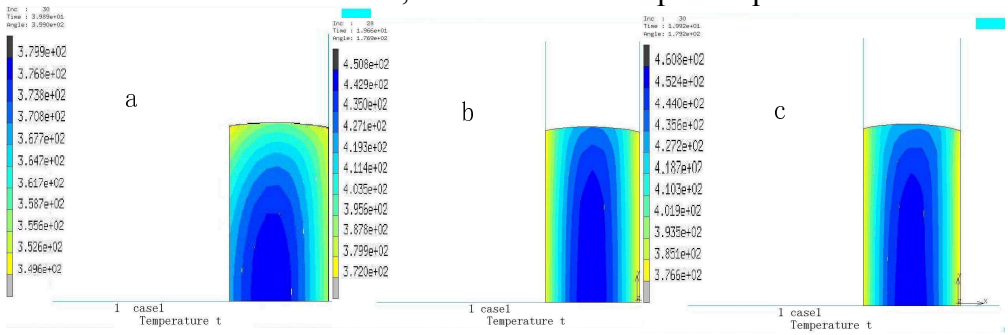

Fig.3 Deformation temperature distribution at step 30

(a: deformation temperature 350 ℃, strain rate of 0.01s^{-1}; b: deformation temperature 350 ℃, strain rate of 0.1s^{-1}; c: deformation temperature 350 ℃, strain rate 1s^{-1})

3.4 Tissue distribution of dynamic recrystallization

Figure 4 is a dynamic recrystallization grain size distribution, in each case, the uneven distribution of the grain sample. Heart large specimen deformed grains relatively small; while reducing the amount of deformation from the inside out, recrystallized grain size also increases. Deformation temperature, the grain size becomes large accordingly, and the strain rate increases, the grain size becomes smaller.

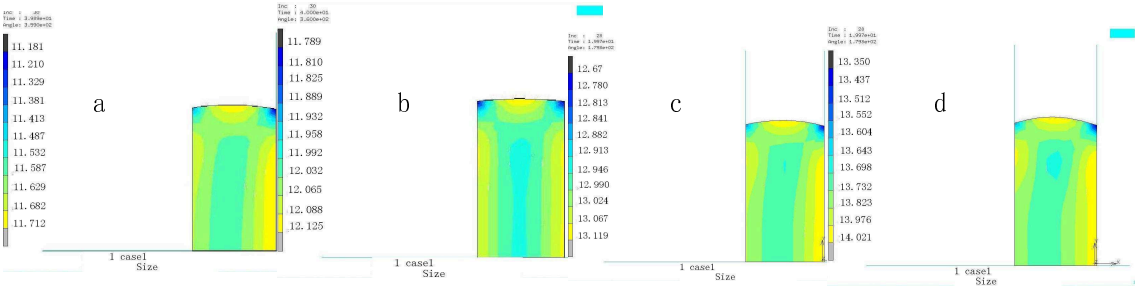

Fig.4 Grain size distribution at Step 20

(a: deformation temperature 300 ℃, strain rate of 0.01s^{-1}; b: deformation temperature 350 ℃, strain rate of 0.01s^{-1}; c: deformation temperature 400 ℃, strain rate 0.01s^{-1}; d: deformation temperature 450 ℃, strain rate 0.01s^{-1})

4 Conclusions

In this paper, the rigid-plastic finite element simulation software Marc / Auto-forge consider the coupling of heat transfer and deformation, and can reflect more fully the compression deformation of AZ61B magnesium alloy. Simulation results show that the stress, strain, temperature inside the uneven distribution of the sample, with a corresponding impact on tissue distribution is not uniform and varies with the deformation process, comparing the calculation results with the experimental data prove the finite element method used herein have higher accuracy in reference to the actual production can predict the deformation member, optimize the process parameters to control the quality of the finished piece.

Keywords: tungsten carbide nanorods; synthesis method; growth mechanism; application

Abstract. Because of the characteristics of both one dimensional nanostructure and excellent physical and chemical properties, the kinds of novel nanomaterials -tungsten carbide nanowires, have important academic significance and practical meaning. The research development of one-dimensional nano- structured tungsten carbide is reviewed. The production methods of one-dimensional nanostructured tungsten carbide, such as nanotubes, nanorods, nanowires and nanoneedles by thermal decomposition technique, vapour deposition technique, magnetron sputtering technique, Eruptive heating technique and template technique respectively are systematically introduced. This paper summarizes the growth mechanisms and the problems involved in the existing synthesis methods. The research tendency is also forecasted.

1. Introduction

Transition metal carbides in general, tungsten carbide in particular, find potential applications due to their special properties, such as high melting point, superior hardness, low friction coefficient, high oxidation resistance, and good electrical conductivity[1-2].WC nanonneedle was shown to have platinum-like behaviour for the chemisorption of hydrogen and oxygen, its applicability as an alternative electrocatalyst of Pt in1970s, the study on production and application of WC nanoneedle has already attracted extensive attention. The early studies showed that this combination of an early transition metal with carbon yielded materials with attractive catalytic activity, stability, selectivity and resistance to poisoning[3-6]. WC nanoneedle has excellent electron emission performance as field emission [7], at the same time it has a very high resolution and good oxidation resistance [8], so tungsten carbide probe was widely used for scanning tunneling microscope (STM) probe and field emission electric device. In addition, tungsten carbide nanowires can be used to intensifying cemented carbide, making PCB carbide micro-drill [9]. The rapid intrinsic growth characteristic of nanometer WC grain during sintering process lead nano-grained cemented carbides with excellent mechanical performances is not acquired [10]. Because of its small size, one-dimensional nano-structured has good dimensional stability of thermodynamics[11]. Preparation of nano-materials is a key issue to control their pore to get a good compactness of nano-particles; it could be settled by adding some nanowires.

In recent years, Several methods are used in preparation of tungsten nanorods and nanoplatelets, which include thermal decomposition method[12,13], vapour deposition[14], magnetron sputtering[7,15], Eruptive heating technique[16] and template[17,18].Therefore, it is of both academic and realistic value to study the preparation methods of one-dimensional nanostructures tungsten carbide and its growth mechanism.

2. Synthesis ofone-dimensional nanostructures tungsten carbide

As one of the perfect one-dimensional nano-materials, tungsten carbide has high strength performance with high surface area and energy, which shows broad applications and is worthy of development.

2.1. Thermal decomposition

Thermal decomposition generally proceeds as a two-step process. First, precursor is formed in a surfactant liquid. The precursor is then resolved at high temperatures in argon atmosphere to obtain one-dimensional nanostructures materials. This method is without template and the simple way.

Aangaraju[12] have reported thermal pyrolysis of the composite hybrid to produce Tungsten carbide nanorods and nanoplatelets. The composite hybrid which is $[C_{21.95}H_{41.19}N_{1.33}]_3PW_{12}O_{40}$was synthesized by dissolving hexadecyltrimethylammounium bromide (CTAB) in distilled water and this solution was added slowly to the 12phosphotungstic acid $(H_3PW_{12}O_{40})_{11}$.And then, pyrolyzed the hybrid in a horizontal tube reactor at the 1000℃.The product was a mixture of WC naorods and nanoplatelets. The diameters of the WC rods are 30-50 nm with varying lengths of 600-1000 nm, and thesizes of the platelets are around 55 nm, see Fig. 1 (a).

Swati etal[13].have also reported a direct pyrolysis to produce of WC Nanotubes at the 1000℃.And the process of researching is: 0.82g $W(CO)_6$ and 0.41g Magnesium powder was introduced into stainless steel cell ,and then put the cell into tube reactor at room temperature under atmospheric conditions，the temperature was raised at a heating rate of 20℃/min, the cell was heated at 900℃ for 3h,the reaction took place at a flowing nitrogen atmosphere, the cell was slowly cooled to room temperature, and 0.842 g black powder was obtained. Energy dispersive X-ray analysis of the sample showed that four phases of MgO, WC, C and α-W_2C in it. The final black product was treated with HCl 35%, used ethanol extract and dried for 12h, what remains is 0.49 g WC Nanotubes. From the Fig. 1 (b), it can be seen that the diameter of WC Nanotubes is 30-70nm, the length is 1-10μm and with several morphology.

2.2. Vapour Deposition

Chemical vapor deposition is the main method among the methods of fabricating nanowires. An implement specific substrates are usually required to ensure nanowires grew. Takayuki Arie etal[14].Synthesized carbide needles on a tungsten tip using a catalytic chemical vapour deposition method and have applied the needle as a STM tip. The tungsten tip was prepared from a tungsten wire with a diameter of 0.3 mm by electrochemical etching in KOH solution. A 50 nm thick Ni film as a catalyst was evaporated onto the tungsten tip. The Ni coated tungsten tip was set in a reactor tube and placed with the point toward the gas flow. The Ni-coated tip was then heated at 750 ℃under a pressure of 17.33Pa in Helium atmosphere for 2 h in order to form round Ni particles. Immediately after the heat treatment, thermal CVD was performed without breaking the vacuum. Benzene was fed as the starting material with a carrier gas of Helium. The carbide needles were synthesized on a tungsten tip by 1 h deposition at the pressure of10Pa. Fig. 1(c) shows the SEM image of the products on a tungsten tip by catalytic CVD，The needles are fabricated on the point of the tungsten tip and have sizes of typically 1μm in length and about 100 nm in diameter.

2.3. Magnetron Sputtering

Wang etal[7].Synthesized tungsten carbide nanowires by the magnetron sputtering, in them reports , WC_x films with thickness in the range of15–60 nm were sputter-deposited on n-type Si(100), 10Vcm substrates. A dc magnetron sputtering system using awater-cooled WC targets (50:50 wt %) with 99.5% purity was used. The deposition was carried out under an argon flow rate of 24 sccm, a dc power of 200 W, and a pressure of 1 Pa at room temperature. The typical deposition rate was measured to be around 0.36 Å/ s. The as-deposited samples were subsequently subjected to thermal annealing in quartz tube furnace with a temperature ranging from 600 to850°C in N_2 ambient for 30 min. the nanowires are all with a straight body. Fig.1 (d) shows the typical SEM image for the 700°C-annealed sample, the typical diameter and length of the nanowires are of 13–15 nm and 0.2–0.3 mm.

2.4 Eruptive heating

Eruptive heating is a special way of synthesizing nano structure materials by controlling the heating rate of reactants in a very short time .Oliveira etal[16] have prepared nano-sized tungsten carbide whisker by using eruptive heating by mixing graphite powder with tungsten powder ,then heat at a ultrafast heating rate of the starting material from the ambient temperature to the target

temperature T=1600℃within fractions of a second. The test piece was held at the target temperature for 30 minit was cooled down naturally to ambienttemperature.Fig.1 (e) show magnified appearances of the nanometer scale WC whiskers grown from the surface have sizes of typically length of several tens of nanometers and about several hundred nanometers in diameter.

2.5Template technique

Nicolas etal[17] present a study of preparation of one-dimensional nanostructures of tungsten carbide by taking the multi-wall carbon nanotubes as a template. The CNTs were added to the precursor aqueous salt solution ($(NH_4)_{10}W_{12}O_{41}\cdot 5H_2O$) and stirred vigorously at 80 °C for 20 min, before the slow evaporation of the solvent at room temperature. The resulting material was further dried overnight at 120 °C and finally calcinated at 350 °C for 2 h. The carburization of WO3 by the CNTs was expected to occur under dynamic vacuum at temperatures ranging between 1000 and 1300°C. Fig.1(f) shows SEM images of the materials synthesized at 1200 °C starting from a mechanical mixture of WO3 and CNTs.

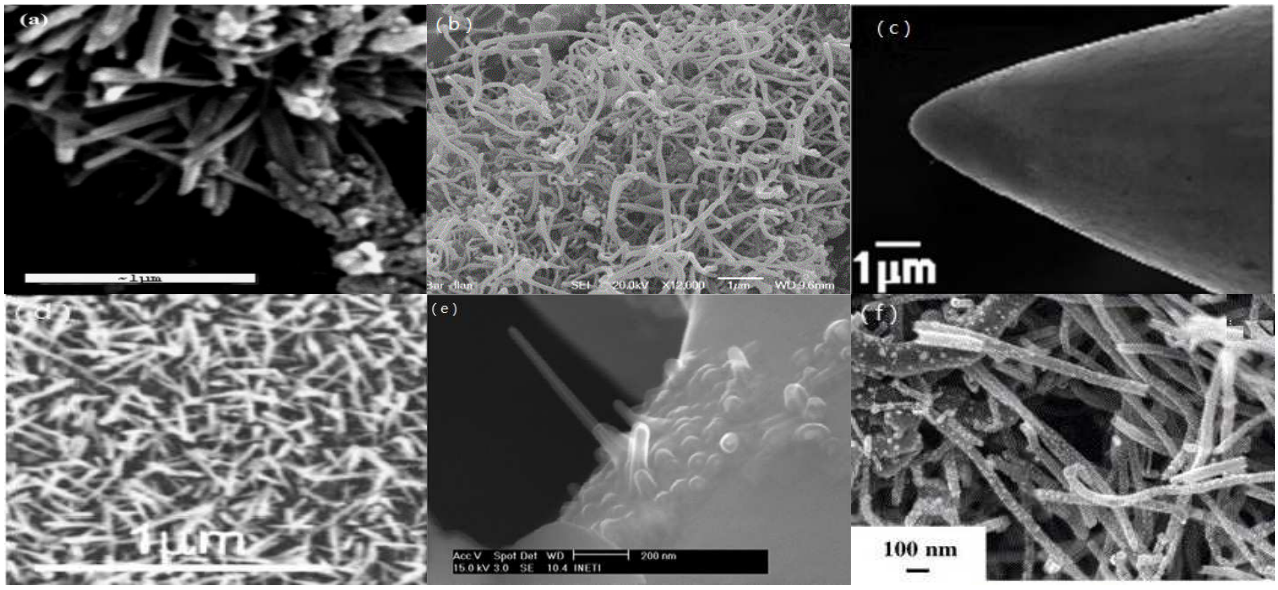

Fig.1 SEM micrographs of the one-dimensionalnano structures

3 The growth mechanisms

Nowadays, theories on VLS [19], VS [20] are often borrowed to explain the growth of one-dimensional nano materials. However, it difficult explain the mechanism of the growth of WC using the traditional growth theory, for example, the detailed mechanism of the VS synthesis of the WC nanowires is unclear. So it is necessary to analyze and summarize on the mechanism of growth of WC nanowires. Meanwhile, in order to provide a universal and controlled reform to guide the preparation of the nanowires.

Takayuki etal[14] believed that nickel play a crucial role in the growth process of WC nanometer needle, but the mechanism is not clear yet. The needles are not grown on a flat substrate but only on a substrate with a curvature, so the curve radius of the substrate is a key factor that affects the nucleation of the WC needle.

Using XRD, Wang etal[7] analyzed the WC_x films. the result to show: the growth of dense nanowires at 700°C, and the disappearance of nanowires at 750–800°C,carbon plays an important role in the growth and collapse of nanowires on annealed WC_x films, the self-catalytic growth of W_2C nanowires should be attributed to the formation of α-W_2C structures caused by carbon depletion in the WC_x films during thermal annealing, in addition, the collapse of W_2C nanowires in samples annealed at temperatures 700°C is due to the nanowires experiencing a structure transformation from α-W_2C(002)phase into grains of β-W phase.

4 Concluding remarks

In recent years, as a one-dimensional material, nanostructure WC have become the focus of attention, with its good physical and chemical properties, WC will surely have broad applying prospects in the new nano-material field. The preparation method was extremely rich and diversified, each with distinct features of its own, but there are disadvantages such as complicated technology, great investment of equipment and strict conditions. Therefore, a feasible and economical ways should be searched, and this will be one of the important technological problems to be solved in a quite long time at present and even in the future.

Keywords: Electrospinning, Composite polymers, Grooved nanofibers

Abstract. An approach to the scale-up of grooved nanofibers via a flat off-centered core-shell structure spinneret has been developed in this study. The spinneret with a flat surface involves shell-holes and off-centered core-needles. The position of the core-needle in the hole and the electrospinning process do influence the formation and structure of the grooved nanofibers. The production rate of the core-shell nanofibers can be enhanced by increasing the hole and needle number of the spinneret. This novel design is expected to provide a promising method towards the massive production of grooved nanofibers.

Introduction

In recent years, many researchers have attempted to enhance the production rate of electrospinning process in more sophisticated ways, such as increasing the number of spinning sites. The previously reported approaches can be generally classified based on the feed method at the spinning site: either a confined or unconfined fluid-volume feed[1]. Our previous work[2] developed a multihole system with a flat spinneret to scale up the productivity of electrospun nanofibers. It was reported that grooved and micro-textured surfaces could provide directional cues for the morphogenesis of cells with a preferred direction[3]. However, scaling up the productivity with conventional needle co-electrospinning system may lead to a complicated device. In this study, the flat off-centered core-shell structure spinneret is developed to enhance the productivity and to improve the fiber morphology of the electrospun grooved nanofibers. Experimental work is carried out to compare the spinning process and fiber morphology of this new design and the conventional needle co-elelctrospinning system.

Experimental

Material Preparation. Polystyrene (PS) (Mw=350 000 g/mol, Aldrich); Elastane PU2180A10 (Mw=70 000~150 000 g/mol^{-1}, BASF); N,N-dimethylformamide (DMF) (Shanghai Chemical Reagents Co., Ltd, China); All of these were used without further purification. Homogeneous PS solution and PU solution with the concentrations of 20 wt% and 7 wt% respectively were prepared by dissolving the corresponding pellets in DMF. The solution was prepared by gently stirring for 5 h with an electric mixer (AM200, Shanghai Only, Inc., China) at the ambient temperature.

Experimental Setup. The scheme of the designed multihole co-electrospinning system is shown in Fig. 1. The novel spinneret consists of an aluminum electrode and a plastic plate made of polytetrafluoroethylene (PTFE). The electrode is a cylinder with 50-mm diameter and 20-mm height. A 2-mm-outer-diameter tube was inserted into the electrode to provide shell solution feeding. The plastic plate with 2-mm thickness was used for creating the electrospinning jet. A solution chamber was formed between the electrode and the plastic plate. Holes with 1.5-mm diameter were drilled in the plastic plate to eject shell solution. Blunt-type needles with 0.8-mm outer-diameter and 0.5-mm inner-diameter were inserted through the electrode and off-centered into the holes to eject core solution. The polymer solutions were forced from syringes via syringe pumps (KDS 220, KD Scientific, Inc. USA) to the spinneret. A voltage power supply (ES-60P 10W/DDPM, Gamma High Voltage Research, USA) was applied to the spinneret and the aluminum foil-grounded collector.

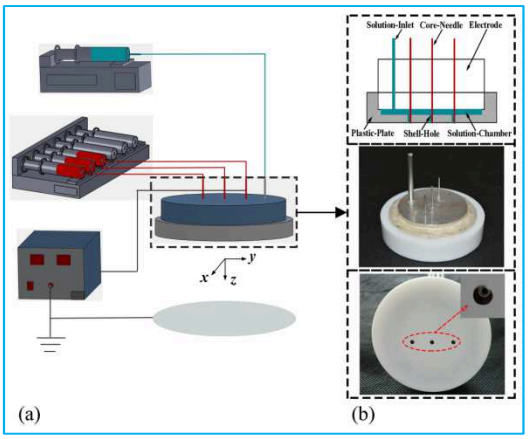

Figure. 1 Schematic of the multihole co-electrospinning system: (a) experimental setup (b) off-centered core-shell structure spinneret.

Characterization. The morphology of the resultant core-shell fibers were observed under a Scanning Electron Microscope (SEM) (JS M- 560 0LV, Japan) after gold coating (coating time is 60 s). A Transmission Electron Microscope (TEM) (JEM-2100, JEOL, Japan) was used to study the internal morphology of the core-shell fibers. The average fiber diameter was calculated from the SEM images using Photoshop Cs 6 (Adobe System Inc., San Jose, CA, USA) software from a collection of 500 fibers.

Results and discussion

Nanofibers with special structures, such as porous nanofibers, grooved nanofibers and nanosprings (or self-crimping nanofibers) have found various applications[4, 5]. In this study, by adjusting the position of the core-needle in the shell-hole (the core-needles is off-centered) and regulating the parameters of the electrospinning process, nanofibers with grooved structures are obtained in a simple way. Fig. 2a shows the SEM image of the grooved nanofibers in the fiber mat produced with the modified flat core-shell spinneret. The inserted SEM and TEM images (Fig. 2b) show the detail structure of the grooved nanofibers. As can be noted, the fibers have remarkable grooves on their surfaces along the fiber axial both in width and depth. The typical fiber morphology of these fibers may be ascribed to the off-centered configuration and the shrinkage of core component. The same solvent of the core and shell component make it easy to dissolve the thin side of shell layer near the central needle.

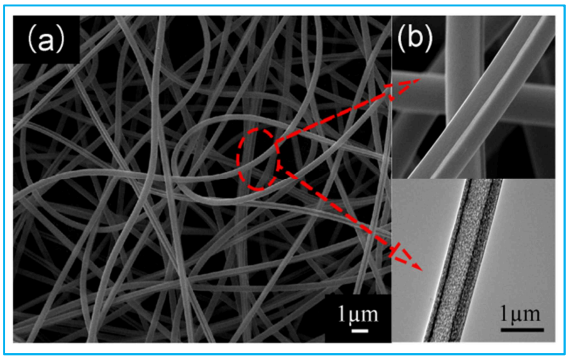

Figure. 2 Special structure fibers: (a) SEM image of the produced grooved fibers (b) Inserted SEM and TEM images of the detail structure of the grooved nanofibers. The working distance is 20cm and the applied voltage is 20kV. The flow rates of the core-needle is 0.5 ml/h and the shell- hole is1.5 ml/h, respectively.

Here, we define the rate of the core as $\boldsymbol{R_c}$, and of the shell as $\boldsymbol{R_s}$, while the parameter $\boldsymbol{p}$ means proportion of $\boldsymbol{R_s}$ to $\boldsymbol{R_c}$. And to illustrate the structure of the grooves on surface of the nanofibers, a parameter f is defined to describe the grooves width accounted for the proportion of the fiber diameter, which can be regulated by adjusting the electrospinning process. It is calculated as $\boldsymbol{f} = \frac{D_g}{D_f} \times 100\%$, where D_g is the width of the grooves and D_f is the diameter of the nanofibers. Fig. 3 further illustrates the proportion of the shell and core rate, the total flow rate and the various voltages effect on the grooves of the nanofibers. Fig. 3a illustrates the changes of f along with the proportion of the shell and core rate ($\boldsymbol{p}$). As we can see that, with the increasing proportion of the shell component, f decreases from 59% to 35% gradually. Fig. 3b shows the changes of f along with the total flow rate $\boldsymbol{R}$ ($\boldsymbol{R}$=$\boldsymbol{Rs}$ + $\boldsymbol{Rc}$) under the proportion of the core and shell rate ($\boldsymbol{p}$) is 4. It shows that $\boldsymbol{f}$ firstly increases from 41% to 45%, then reduces to 35% rapidly.Fig. 3c illustrates the changes of $\boldsymbol{f}$ along with various voltages. As the same trend of R, $\boldsymbol{f}$ grows from 25% sharply, and then down to 35%. By regulating the special grooved structure, the off-centered core-shell nanofibers can be have more applications on the organization applications and molecular templates.

Scale-Up Analysis

Under the same conditions, the productivity of the co-electrospinning setup is determined by the number of the jets. For the three-hole flat core-shell spinneret, the productivity is about 3 times of the conventional setup, which is about 1.5ml/h for the core-needles and 4.5 ml/h for the shell-holes. The production rate of core-shell fibers can be scaled up by increasing the hole and needle numbers.

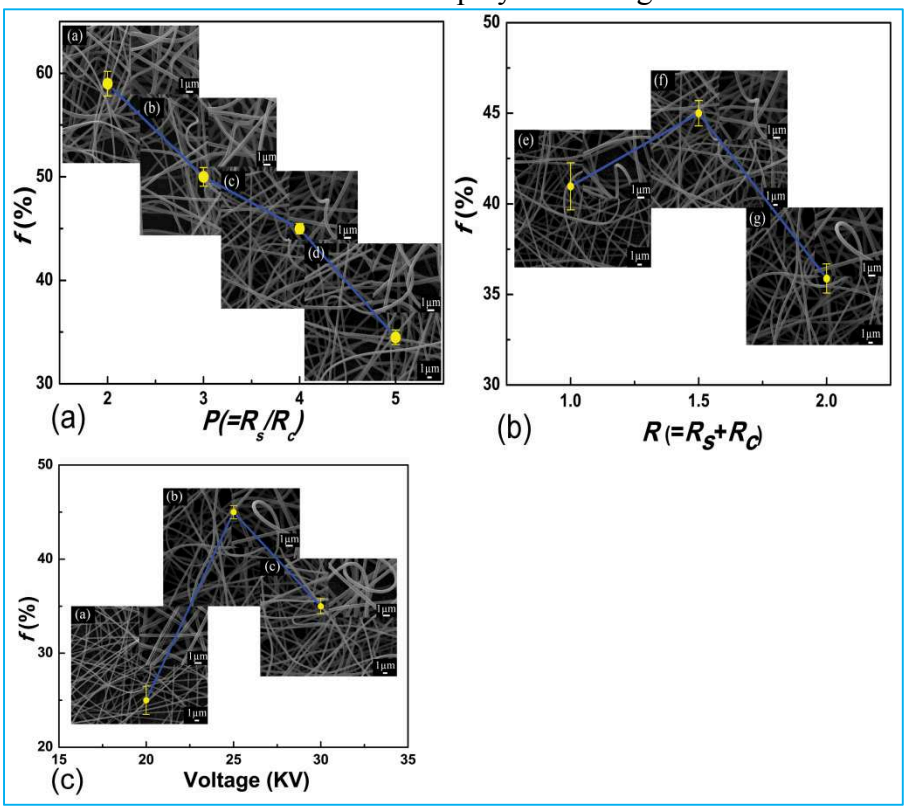

Figure. 3 The effect of f along with (a) the proportion of shell rate Rs to core rate Rc (Rs + Rc =1.5ml/h) (b) the flow rate of R=Rs+ Rc (p=4:1) (c) various voltages.(The working distance keeps 20cm.)

Conclusion

A co-electrospinning setup for the scale-up of the grooved nanofibers has been developed. We compared fiber morphology under different electrospinning process produced by the new designed flat off-centered core-shell structure spinneret. This method provides a promising method towards the massive production of core-shell nanofibers.

Keywords: Poly (p-phenylene benzobisoxazole) (PBO), Multiwalled carbon nanotube, Copolymerization.

Abstract. Multiwalled carbon nanotube (MWCNT) was subjected a copolymerization reaction with 4, 6-diaminoresorcinol salt (DAR•2HCl) and terephthalic acid (TA) in polyphosphoric acid (PPA) by Friedel-Crafts acylation reaction without any acid treatment or modification. The structure and morphology of the as-prepared poly (p-phenylene benzobisoxazole) (PBO)/MWCNT nanocomposites were characterized by X-ray diffraction (XRD) and scanning electronic microscope (SEM). The SEM images indicated that MWCNTs can disperse in PBO matrix uniformly without agglomeration and MWCNTs have been introduced into PBO matrix by covalent bonding via Friedel-Crafts acylation between MWCNTs and TA.

Introduction

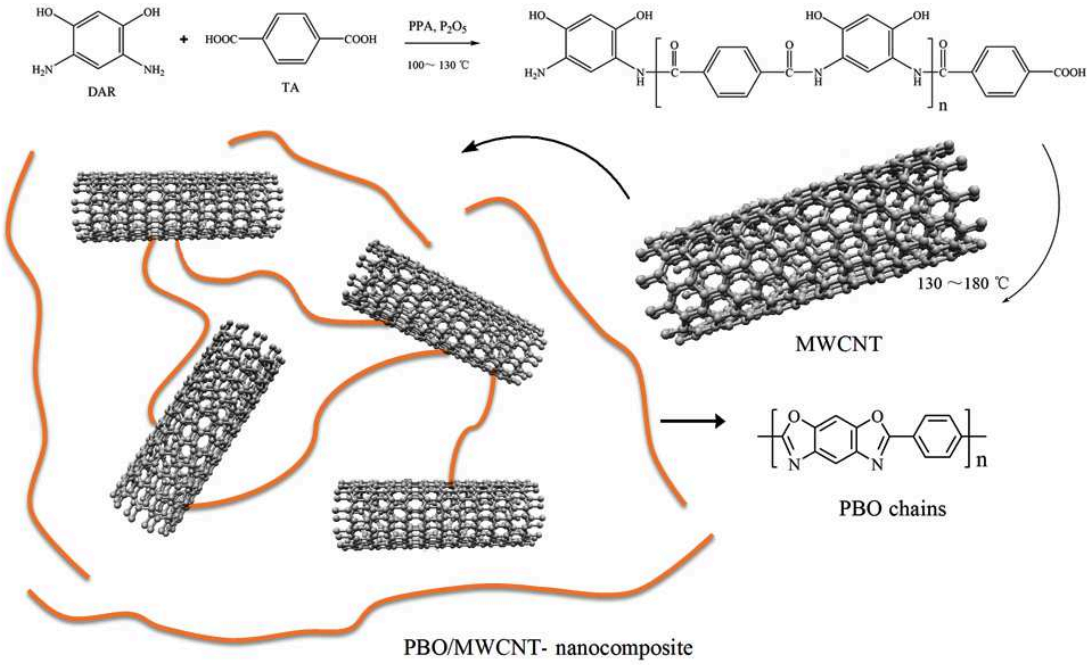
Polybenzobisoxazole(PBO), possessing high tensile strength, high temperature resistance and excellent chemical resistance [1, 2], shows a widely application in aviation, spaceflight, and other special fields. However, only about 15% of the theoretical tensile strength has been achieved in the momericialized PBO fibers attributed to the low-molecular length (about 200 nm for fiber spinning) and defects [3]. To fully exploit the mechanical properties of PBO, several studies have been made on PBO/CNT composites to take advantage of longer length of CNTs compared with that of PBO molecular chain [4, 5]. And all the synthetic routes of PBO/CNT nanocomposite reported before had need to acid treatment on CNT to introduce carboxyl group into CNT (CNT-COOH). In this study, we prepared PBO/MWCNT nanocomposite via a one pot reaction of 4, 6-diaminoresorcinol salt (DAR•2HCl) and terephthalic acid (TA) with MWCNTs in polyphosphoric acid (PPA) by Friedel-Crafts (F-C) acylation [6, 7]. Unlike other synthetic routes reported before [5, 8, 9], the synthetic route for PBO/CNT nanocomposties does not need any acid treatment or modification on CNT. Moreover, the structure and morphology of PBO/MWCNT nanocomposites have been investigated in this study.

Experiment

Materials

4,6-diaminoresorcinol dihydrochloride (DAR• 2HCl) was obtained from commercial sources and dried under vacuum at 40℃ for 24 h, terephthalic acid (TA) was purchased from Shanghai Lingfeng Chemical, the reaction medium, poly(phosphoric acid) (PPA) with 80.8% phosphorus pentoxide (P_2O_5), was freshly prepared using as-received phosphoric acid and P_2O_5 (Shanghai first Chemical

Co., Shanghai). MWCNT with an average diameter of 40～60 nm was provided from Nanotech Port Company, Shenzhen, China. All reagents were used without further purification.



Scheme 1 Schematic illustration of preparation of PBO/MWCNT nanocomposite

The preparation of PBO/MWCNT nanocomposites

The PBO/MWCNT nanocomposites were synthesized by a one-step procedure from DAR•2HCl, TA and MWCNT with PPA as the condensing medium. In a typical synthesis of PBO/MWCNT nanocomposite with MWCNT composition of 2 wt. %, 2 g DAR•2HCl, 1.56 g TA and 0.04 g MWCNT were mixed together with 7.51 g P_2O_5 and 11.62 g PPA in a three-necked separable flask equipped with a mechanical stirrer in the presence of nitrogen atmosphere. The reaction mixture was stirred for 1 h at the room temperature to ensure full mixing of the monomers. The reaction temperature was raised to 90℃ and held for 6 h in vacuum, then to 100℃ and held for 6 h, and to 110℃ and held for 6 h. After the hydrogen chloride in DAR• 2HCl was fully removed, the reaction temperature was raised to 120℃ for 12 h in nitrogen, then to 130℃ for 12 h, and then to 180℃ for 12 h. The highly viscous polymerization dope (dark green in color) in PPA was precipitated in water and purified by extraction of the PPA with water for 1 day. The composite was desiccated at 80℃ in a vacuum oven.

Results and discusstions

To investigate the effect of MWCNTs on the ordered structures of PBO matrix, XRD patterns of PBO/MWCNT nanocomposites were measured and shown in Fig. 1. Two typical diffraction peaks at 2θ=15° and 26° for polybenzazole can be observed in the spectrum of PBO. Diffraction peaks for MWCNTs are not detectable in spectra and all the diffraction peaks can be assigned to the ordered structure of PBO in PBO/MWCNT nanocomposites. This indicates that the ordered structure of PBO matrix largely remains after introducing MWCNT, consistent with earlier reports for PBO/CNT composites [10].

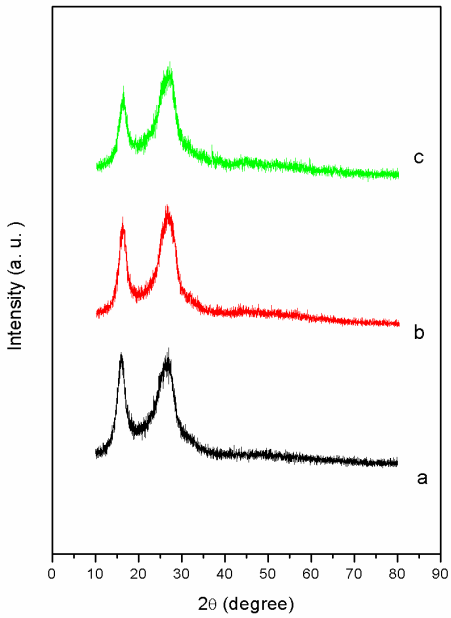


Figure 1 The Wide-angle X-ray diffraction patterns of PBO/MWCNT nanocomposites with MWCNT compositions of (a) 0 wt%, (b) 2 wt% and (c) 4 wt%

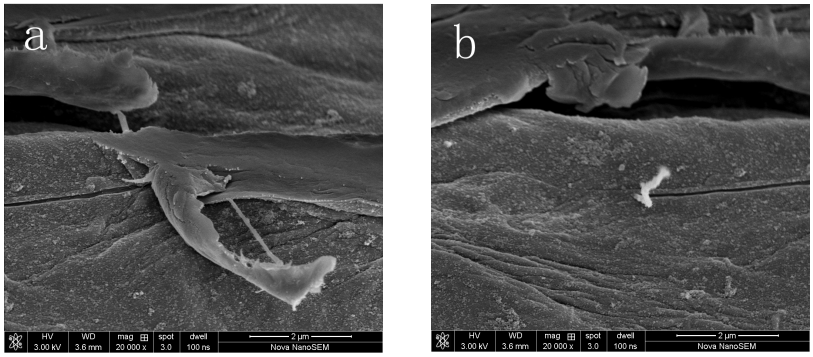

Figure 2 SEM images of PBO/MWCNT nanocomposites of the cross-section, the scalebar of both a and b is 2 μm

Homogeneous dispersion of MWCNTs in PBO matrix is one of the most important necessities in fully taking advantage of the excellent physical property of MWCNTs. The morphology of resulting products was characterized by SEM, as shown in Fig. 2. SEM images in Figs. 2a and 2b show that MWCNTs uniformly disperse in PBO matrix without agglomeration. Moreover, these images also demonstrate the MWCNTs have been introduced into PBO matrix by covalent bonding via Friedel-Crafts acylation between MWCNTs and TA.

The thermal behavior of PBO and PBO/MWCNT nanocomposites is studied by TG (Fig. 3). In the TG curves of all the samples, only one degradation step at about 660℃ owing to the decomposition of the PBO molecular chains is observed. The results in Fig. 3 indicate that PBO/MWCNT nanocomposites still mantain PBO's outstanding thermostability without appreciable weight loss up to 680℃. Remarkably, the thermal stabilities of all the PBO/MWCNT nanocomposites are better than that of PBO when it is below 650℃ with higher on-set thermal degradation temperature T_d. Moreover, with increasing the amount of MWCNT, the larger residual weight of PBO/MWCNT nanocomposites. It can be concluded that the MWCNTs homogeneously dispersed in PBO matrix and the covalent bonding at the MWCNT/PBO interface are expected to improve the thermal stability of PBO/MWCNT nanocomposites.

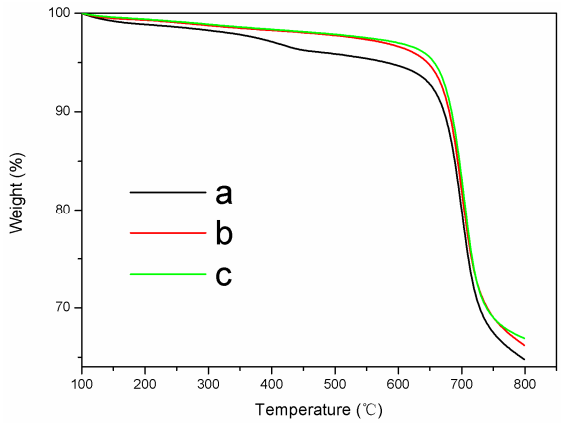

Figure 3 The thermal behavior of PBO/MWCNT nanocomposites with MWCNT compositions of (a) 0 wt%, (b) 2 wt% and (c) 4 wt%

Conclusion

In this study, a series of PBO/MWCNT composites with different MWCNT contents are synthesized through in-situ polymerization via Friedel-Crafts acylation reaction. The structure and morphology of the obtained PBO/MWCNT composites have been investigated. The results show that MWCNTs uniformly disperse in PBO matrix without agglomeration and MWCNTs have been introduced into PBO matrix by covalent bonding via Friedel-Crafts acylation between MWCNTs and TA.

Keywords: contaminated sites, Chlorobenzene,O-dichlorobenzene,Oxidant,Site remediation.

Abstract. this study intends to compare through the experiment research of potassium permanganate, Fenton reagent, sodium persulfate, hydrogen peroxide, four kinds of commonly used oxidant chlorobenzene in contaminated soil, the removal effect of O-O-dichlorobenzene;, selected a typical ground soil bioremediation is the best antioxidant effect. Research under the condition of different on the dose, 4 kinds of oxidants to chlorobenzene and O-O-dichlorobenzene; removal effect. Combined pollution ground soil properties screen of chlorobenzene in contaminated soil, the highest removal rate of dichlorobenzene oxidant and best delivery dosage, to apply typical ground soil bioremediation, the results show that the effect is the best Kmno4.

With the adjustment of industrial structure and layout of the city,facing a lot of old chemical plant relocation or closure of the situation,some of the original factory land into a green city,commercial and even residential areas. In the process,these companies left in the original area of contamination to the environment and the health of residents around poses a serious threat. Therefore,in view of the characteristics of contaminated sites and repair needs,using the appropriate repair techniques for contaminated sites for efficient,fast and safe repair is necessary.

Relocation site for the chemical industry where the typical contaminated sites,mainly from the production process of organic pollutants and sewage process. Chemical companies in the relocation of contaminated sites,and chlorobenzene substances is a common legacy pollutants. Since chlorobenzene substances chemically more stable,but also has toxicity,it is difficult to be natural microbial degradation,likely to cause pollution of the environment of persistent and dichlorobenzene has a strong stimulating effect,long-term exposure harmful to human skin,conjunctiva and respiratory organ irritation,and cause acute or chronic neurological disorders[1,2]. Therefore,the study of chlorobenzene substances contaminated soil remediation technology has important practical significance.

At present,for contaminated soil organic matter oxidation reagents major repair hydrogen peroxide,Potassium permanganate,Fenton reagent and Activated persulfate,these types of oxidants have their optimum reaction conditions and the type of contaminants. Fenton reagent and potassium permanganate on the removal of soil organic matter,there have been a number of related studies[3,5]. Couttenye use of electron spin resonance, etc. (EPR) detects the acidic and neutral (pH=2~7)· SO-4 in the presence condition,the presence of an alkaline (pH>12) under the conditions of· OH. Therefore, the use of activated persulfate itself and generated·SO-4 and·OH radical degradation activity of organic pollutants in wastewater,groundwater and soil organic matter management have potential applications,recently to study abroad focus [6].

Materials and methods

Selected soil

Puts the soil 100. 0 g of the sieve after removing impurity in the beaker, says apply adequate amount of Chlorobenzene and O-dichlorobenzene; soluble in acetone solution, then mixed with 1000. 0 g original soil, configured to concentration of 100 mg/kg 1000. 0 g of contaminated soil. To place it in the fume hood avoid light preservation, acetone volatile backup with completely, the soil aging one week after measuring the concentration of Chlorobenzene and O-dichlorobenzene;.

The preparation of oxidant solution

Respectively according to take the right amount of potassium permanganate, sodium persulfate, preparation of 0. 4mol/L, 0. 4mol/L the oxidant liquid reserves of 1000 mL, avoid light preservation. Fenton reagent preparation: the concentration of 30%H2O2 and 0. 4 mol/LFeSO4 five to one preparation by the molar concentration of 1000 ml. Hydrogen peroxide concentration of 30% H2O2.

The experiment design

1. 31 Determination of the original soil water content,contaminants and simulate pollution soil samples after aging contaminants.

In the early stage of the experiment,the physical and chemical properties of soil were determined,the main physical and chemical properties of the soil including soil texture, moisture content,soil organic contaminants,and so on.

The original soil soil samples of chlorobenzene and dichlorobenzene detection Soil sample pretreatment by ultrasonic extraction,contaminants using gas chromatography tes

This experiment chooses four kinds of oxidant,each antioxidant soil water ratio of five to one for processing the pollution of soil,and set up three groups. Oxidant concentration in the same experiment,but choose different delivery dosage (1ml,2ml,3ml,4ml,5ml) and oxidant in the process of the experiment of spraying manner, antioxidants on the dose see (table 1).

Table 1: The moisture content of 20% to simulate pollution soil (soil water ratio 5:1)oxidation treatment

oxidant	reagent	concentration	dose
Potassium permanganate	KMnO4	0. 4mol/L	1ml, 2ml, 3ml, 4ml, 5ml
Sodium persulfate	Na2S2O8	0. 4mol/L	1ml, 2ml, 3ml, 4ml, 5ml
Hydrogen peroxide,	H2O2	0. 4mol/L	1ml, 2ml, 3ml, 4ml, 5ml
Fenton reagen	H2O2 FeSO4	30% 0. 4mol/L	1ml, 2ml, 3ml, 4ml, 5ml

Will response after the soil samples of natural air drying and air drying after the soil samples using ultrasonic extraction method to extract,gas chromatography to determine the content of chlorobenzene and dichlorobenzene.

Sample analysis

Determination of the concentration in the soil

Extraction method

Soil samples:after antioxidant treatment of soil,after natural drying. Add 25mL of hexane solution points three times after ultrasonic extraction 1. 5h,collect extract with right amount after 500℃ muffle furnace burning after 4 hours of Na2SO4 to remove moisture,impurities in the solvent is overmuch,can be over 0. 45um microporous membrane filter in removing impurity.

The chromatographic conditions

Chromatography is set according to the national standard method of determination of chlorobenzene

In the recovery liquid concentration determination

In the recovery liquid concentration determination:take inlet chromatography for determination of directly.

Results analysis and discussion:

Infected aging after two weeks of chlorobenzene content in the contaminated soil samples is 18. 5 mg/kg, O-dichlorobenzene content is 39. 0 mg/kg. Oxidant mixture concentration is 0. 1mol/L.

After four antioxidant treatment measure the contaminants and removal rate as shown in the figure below:

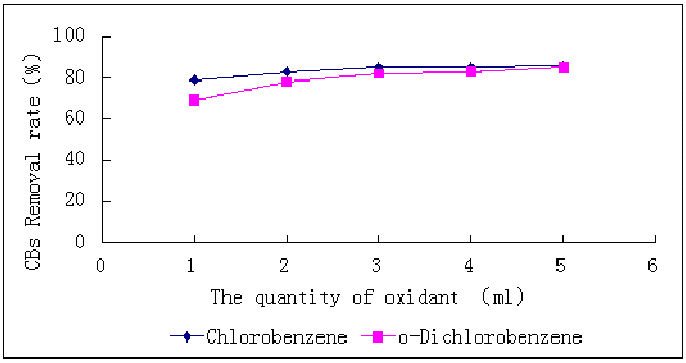

Figure 1: Kmno4 for two kinds of pollutants removal rate

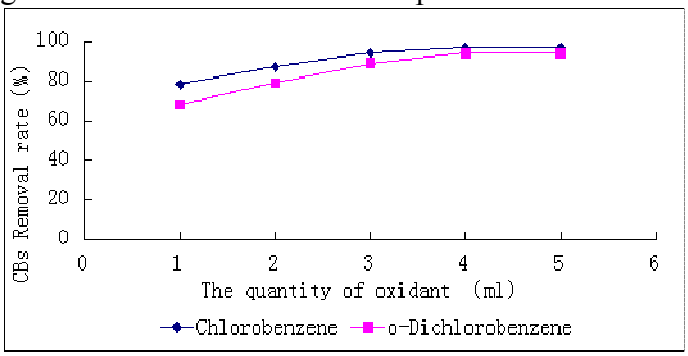

Figure 2: Na2S2O8 for two kinds of pollutants removal rate

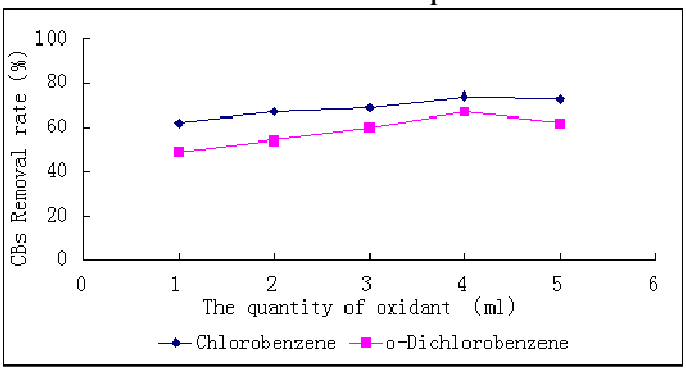

Figure 3: H2O2 for two kinds of pollutants removal rate

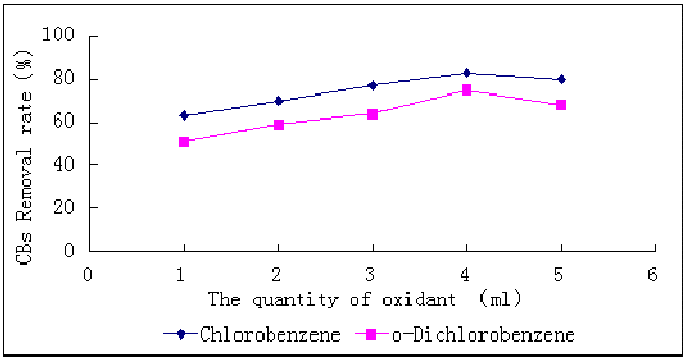

Figure 4: Fenton reagent for two kinds of pollutants removal rate

1 From the above four graphs, the same type of oxidizer in the oxidation effect of different concentrations, generally within a certain range, the oxidizing agent is measured with increased oxidative better, up to 97%.

2 Seen from the above diagram,the simulation polluted soil after three different oxidizing agent significantly reduce pollutants,oxidizing agents,in the removal of the same dose of sodium persulfate is best, followed by high potassium permanganate.

3 Through the above chart shows that under the condition of considering economic benefit and effect of removing, oxidant dosage for 4ml effect.

Keywords: PI3K/mTOR Inhibitors; 4-Morpholinothieno[3,2-*d*]pyrimidine; Chromone; Anticancer activity

Abstract. A series of 4-morpholinothieno[3,2-*d*]pyrimidine derivatives containing chromone moiety (**5a-5e**) were synthesized and their structures were confirmed by ^{1}H NMR and MS spectrum. The synthesized compounds were evaluated for their cytotoxicity against three cancer cell lines (PC-3, H460, SGC-7901). Two of them exhibited moderate cytotoxicity and high-selectivity against one or more cell lines. At 10μM levels, the inhibition rate of compound **5c** against SGC-7901 cell lines was 58.9%, and that of compound **5d** against PC-3 cell lines was 56.4%.

Introduction

Cancer is one of the major diseases that threaten human health. The incidence of cancer is the second only to cardiovascular and cerebrovascular diseases, and it's mortality rate is the highest among all diseases [1]. Currently, there are three main methods for treating the cancer: surgical resection, chemotherapy, and radiation therapy. However, with the advancement of science, the limitations of these three treatments are also increasingly prominent. Therefore, searching for highly efficient and safe chemotherapeutic agents for treating cancer remains desirable.

Recent studies have found that the phosphatidylinositol 3-kinase(PI3K) and its downstream protein kinase B(Akt/ PKB), mammalian target of rapamycin (mTOR) consisting of PI3K-Akt-mTOR signaling pathway controls many important biological processes in the development process of tumorigenesis[2-3]. Therefore, inhibition of this pathway had become a hot topic in cancer prevention and targeted therapy.

After years' effort of the researchers, many small molecule inhibitors of this pathway were entered the clinic study [4-6]. Among these compounds, thienopyrimidines are the most important of all types, as well as the earliest in this pathway. The most representative compound is GDC-0941 (Fig. 1), which is a selective PI3K inhibitor currently undergoing Phase I clinical trials[4]. The structure–activity relationships (SARs) studies indicated that the 4-morpholinothieno[3,2-*d*] pyrimidine scaffold played a key role in their antitumor activity[4,7].

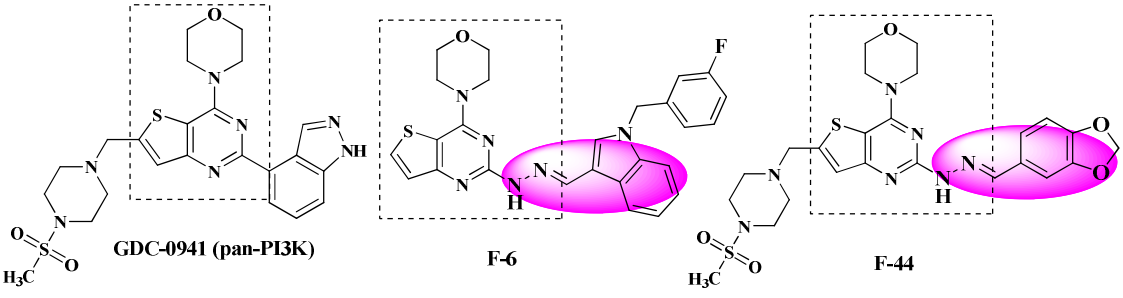

Fig. 1 Structures of GDC-0941 and the representative compounds in our previous study

In our previous study [8,9], with GDC-0941 as a lead compound, we designed and synthesized a series 4-morpholinothieno[3,2-*d*] pyrimidine derivatives with an arylmethylene hydrazine moiety at

C-2 position(Fig.1). Among these compounds, most of them showed excellent anti-tumor activity. The 3D-QSAR study found that the introduction of arylmethylene hydrazine at C-2 position significantly enhanced the anti-tumor activity and selectivity.

In this study, replacing the aryl group with the active pharmacophore chromone, a series of 4-morpholinothieno[3,2-*d*]pyrimidines (**5a~5e**) which had not been reported yet were designed and synthesized. All the target compounds were evaluated for their cytotoxicity against three cancer cell lines (PC-3, H460, SGC-7901).

Materials and methods

All melting points were obtained on a Büchi Melting Point B-540 apparatus (Büchi Labortechnik, Flawil, Switzerland) and were uncorrected. 1H-NMR spectra were performed using Bruker 300/400 MHz spectrometers (Bruker Bioscience, Billerica, MA, U.S.A.) with TMS as an internal standard. Mass spectra (MS) were taken in electrospray ionization (ESI) mode on Agilent 1100 LC-MS (Agilent, Palo Alto, CA, U.S.A.). All the materials were obtained from commercial suppliers and used without purification, unless otherwise specified. Yields were not optimized. TLC analysis was carried out on silica gel plates GF254 (Qindao Haiyang Chemical,China).

Synthesis of compounds

Substituted chromone aldehyde derivatives (D1-D5).

The synthesis of substituted chromone aldehyde derivatives was according to the procedures in our previous research[10].

4-(2-hydrazinylthieno[3,2-*d*]pyrimidin-4-yl)morpholine (4)

The synthesis of 4-(2-hydrazinylthieno[3,2-*d*]pyrimidin-4-yl)morpholine(**4**) was according to the procedures in our previous researches[8,9].

General Procedure for Preparation of Compounds 5a-5e.

A mixture of 4-(2-hydrazinylthieno[3,2-*d*]pyrimidin-4-yl)morpholine (0.1 g, 0.40 mmol), substituted aldehyde (**D1-D5**, 0.42 mmol) and a drop of glacial acetic acid in absolute ethanol (8 mL) was refluxed for 2–5 h. The mixture was cooled, separated by filtration and washed with EtOH to give off a yellow solid. The crude product was recrystallized from ethanol or purified by chromatography on silica gel using MeOH/CH_2Cl_2 to afford yellow solids **5a-5e** respectively.

(*E*)-6-isopropyl-2-((2-(4-morpholinothieno[3,2-*d*]pyrimidin-2-yl)hydrazono)methyl)-4*H*-chromen-4-one (5a)

Yellow powder. Yield 49%. mp 163-165°C. ESI-MS m/z: 450.1 $(M+H)^+$,448.2 $(M-H)^-$. ^{1}H NMR (400 MHz, DMSO) δ 10.98 (s, 1H), 8.75 (s, 1H), 8.26 (s, 1H), 8.13 (d, *J* = 5.6 Hz, 1H), 7.98 (s, 1H), 7.80 (d, *J* = 8.8 Hz, 1H), 7.70 (s, 1H), 7.27 (d, *J* = 5.4 Hz, 1H), 3.94 (s, 4H), 3.80 (s, 4H), 3.13 (d, *J* = 7.5 Hz, 1H), 1.30 (d, *J* = 7.0 Hz, 6H).

(*E*)-6-fluoro-2-((2-(4-morpholinothieno[3,2-*d*]pyrimidin-2-yl)hydrazono)methyl)-4*H*-chromen-4-one (5b)

Yellow powder. Yield 58%.mp 228-231°C. ESI-MS m/z: 426.1 $(M+H)^+$.

Yellow powder. Yield 55%.mp 223-225°C. ESI-MS m/z: 422.2 (M+H)+

(*E*)-2-((2-(4-morpholinothieno[3,2-*d*]pyrimidin-2-yl)hydrazono)methyl)-4-oxo-4*H*-chromene-6-carboxylic acid (5e)

Yellow powder. Yield 69%.mp 280-282°C. ESI-MS m/z: 452.1 $(M+H)^+$,450.1 $(M-H)^-$.

Biological Evaluation

The cytotoxic activities of compounds were evaluated with human lung cancer (H460), human prostate cancer (PC-3) and human Gastric cancer (SGC-7901) cell lines by the standard MTT assay *in*

vitro, with GDC-0941 as the positive controls. The cancer cell lines were cultured in minimum essential medium (MEM) supplement with 10% fetal bovine serum (FBS).Approximately 4×10^3 cells, suspended in MEM medium, were plated onto each well of a 96-well plate and incubated in 5% CO_2 at 37°C for 24 h. The test compounds at indicated final concentrations were added to the culture medium and the cell cultures were continued for 72 h. Fresh MTT was added to each well at a terminal concentration of 5 μg/mL and incubated with cells at 37°C for 4 h. The formazan crystals were dissolved in 100 μL DMSO each well, and the absorbency at 492 nm (for absorbance of MTT formazan) and 630 nm (for the reference wavelength) was measured with the ELISA reader. All of the compounds were tested three times in each of the cell lines.

Results

Chemistry

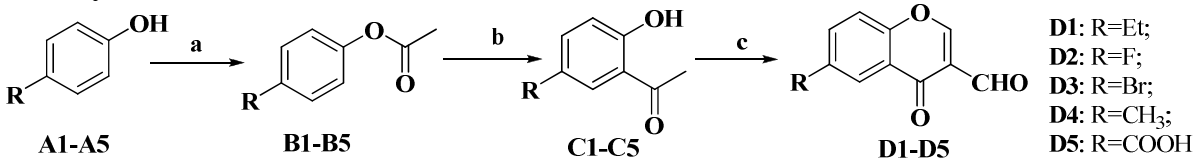

Fig. 2 Synthetic route of chromone aldehyde derivatives(**D1-D5**)

Reagents and conditions: (a) Ac_2O(1.05eq) ,conc. H_2SO_4,0°C, 1h; (b) anhydro $AlCl_3$, 120°C,6-7h; (c) DMF,$POCl_3$, r.t,12h.

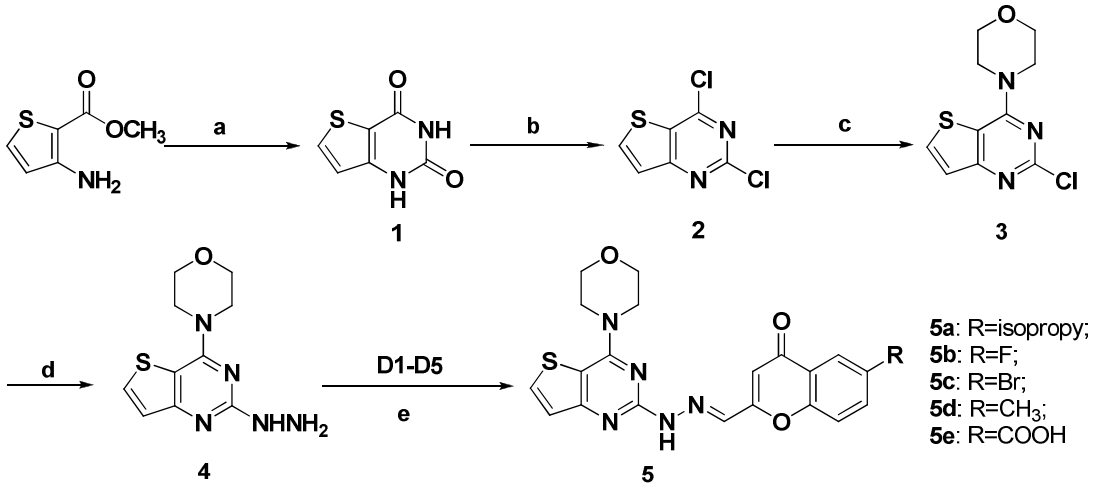

Fig. 3 Synthetic route of 4-morpholinothieno[3,2-d]-pyrimidine derivatives(**5a-5e**)

Reagents and conditions: (a) 5 eq urea, 190°C, 2.5 h; (b) $POCl_3$, DMF (cat.), reflux, 8 h; (c) 2.1 eq morpholine, MeOH, 0°C, 30 min, r.t., 1–2 h; (d) 80% $NH_2NH_2\cdot H_2O$,reflux, 8–10 h;(e) EtOH, reflux, 2–4h.

Biological assay

The in vitro anticancer activities of above synthesized compounds were studied on the PC-3, H460 and SGC-7901 cell. The test results of compounds **5a-5e** were listed in Table 1.

Table 1.The inhibition rate of PC-3, H460 and SGC-7901 cell by **5a-5e** at 10μM levels

Compound	Inhibition rate at 10μM (%)		
	PC-3	**H460**	**SGC-7901**
5a	32.7	12.3	33.3
5b	24.7	5.7	34.9
5c	39.6	30.6	58.9
5d	56.4	22.2	20.7
5e	ND	ND	ND
GDC-0941	74.1	58.7	70.4

ND：Not determined

From Table 1, we could see that some of the target compounds showed moderate activity against the tested cancer cell lines and most of them showed more activity against SGC-7901, PC-3 cancer cell lines than H460 cell line. The substituents of chromone aldehyde at C-6 position played a key role to the activity, especially the bromine atom (**5c**) and methyl group (**5d**).

At 10μM levels, the inhibition rate of compound **5c** against SGC-7901 cell line was 58.9%, and the inhibition rate of compound **5d** against PC-3 cell line was 56.4%. Although their inhibition rate is lower than GDC-0941, it still showed that the introduction of chromone moiety is essential to this kind of compounds. This result suggested that 4-morpholinothieno[3,2-*d*]-pyrimidine derivatives bearing chromone moiety is worthy to study further.

Conclusions

In conclusion, a series of 4-morpholinothieno[3,2-*d*]-pyrimidine derivatives bearing chromone moiety were designed, synthesized and evaluated for their activity against the cancer cell lines. The pharmacological results indicated that some of them exhibited moderate cytotoxicity and high-selectivity against one or more cell lines. And compounds **5c**, **5d** demonstrated better anticancer activity than other compounds. Further modification and SAR studies based on 4-morpholino thienopyrimidine are ongoing in our group.

Keywords: vertical flow constructed wetland; ceramsite; canna; adsorption; nitrification and denitrification

Abstract. Haydite as filler, selecting canna as wetland plant denitrification effect of vertical flow constructed wetland research. In terms of the mechanism of denitrification, in view of the ceramsite adsorption, microbiological nitrification and denitrification reaction, plants absorb test in three aspects and to study the effect of various factors. Adsorption experiment, ceramsite to NH_4^+–N adsorption reached the maximum at 4 h, adsorption intensity is 0.0045 mg/g, device of NH_4^+–N in the running 92 days maximum theory is 1296 g. Microbial average intensity of nitration was 0.750 $mg.h^{-1}.kg^{-1}$. The denitrifying intensity of 1.090 $mg.h^{-1}.kg^{-1}$. Canna root, stem and leaf nitrogen content were increased by 7.73%, 7.73% and 9.92% per plant cannas average of 1.189 g, nitrogen absorption during the running period of 10 plants absorb about 11.89 g. Vertical flow constructed wetland, the choice of spherical light ceramsite substrate adsorption strength, suitable for packing of wetland. Canna better effect on the absorption of nitrogen, of the three microbes plays a main role for denitrification.

Introduction

In recent years, with the rapid development of economy, the water environment deteriorating, 50% more than 80% of the lakes and river in China by different levels of pollution, eutrophication of lakes in severe cases nationwide.Nitrogen is the key to cause the pollution index, thus control the eutrophication of water bodies must focus on nitrogen removal. Artificial wetland is sewage flows through kinds of plant medium, the filtration, sedimentation, adsorption, such as physics, chemistry, and pollutants and microorganism various kinds of biochemical reaction to remove the pollutant treatment process [1], because of its low energy consumption, easy management, has the advantages of landscape effect is widely used. Artificial wetland according to different structures can be divided into the surface flow, undercurrent and vertical flow three types [2], the vertical flow constructed wetland in three denitrification effect is relatively outstanding. Packing is the carrier of artificial wetland plants, microorganisms, to purify the pollutants in wastewater has important role. For a long time, with zeolite, gravel, fly ash as the research of artificial wetland packing is more, such as such as Zhang Yingying [3], etc., but with ceramsite packing research is less. The value of the spherical light ceramsite as artificial wetland packing were studied The main mechanism of nitrogen removal in constructed wetland system is a microbial nitrification and denitrification reaction. In terms of the choice of wetland plant, studies have shown that ecological wetland in canna on nitrogen uptake is larger, the highest can reach more than 80%. Therefore ceramsite as matrix of wetland plants, canna for vertical flow constructed wetland research on the treatment effect of the low concentration contaminated water is more worthy of promotion.

Nitrogen Removal Factor Test

1.1Research of Ceramic Matrix of NH_4^+-N and NO_3^--N Isothermal Adsorption Effect

Table 1 Performance indexes of spherical light ceramsite filler physics [4]

Particle size	Packing density	Density	porosity	Non-uniform coefficient	Specific surface area
mm	g/cm^3	g/cm^3	%	-	cm^2/g
0.5-32	0.7-1.2	1.2-2.6	55-58	K_m=1.80	2×10^4-1.5×10^5

Materials: spherical light ceramsite, $(NH_4)_2SO4$, Nessler's reagent, sodium potassium tartrate and other reagents were analytically pure.

Test Method: With NH_4^+-N =100mg/L, PH=7.3. 100g ceramic drying at 105℃, after sterilization in an Erlenmeyer flask, the 200ml solution, and the absorbent cotton stuffed bottle. Oscillation in constant temperature oscillation box 25 ℃, 150r/min, in 1, 2, 3, 11, 12... The sampling, 24 hours two times, 10ml each time, every time after sampling with culture medium supplement. The supernatant of NH_4^+-N concentration in solution, two times the average. The saturated adsorption capacity by variation of NH_4^+-N reaction in solution to represent. In addition, the test of ceramsite saturated adsorption capacity of NO_3^--N method for the same.

Method: NH_4^+-N : Nessler's reagent colorimetric method; NO_3^--N: UV Spectrophotometry

Formula:M= (C-c) V/ (1000W)

M:the adsorption strength, ceramic mg/g; C, c:concentration, ammonia nitrogen adsorption and solution of mg/ L; V:the solution volume, taken as the test of mL; W:ceramic mass, g.

1.2 Study on Strength of Microbial Nitrification and Denitrification

The optimum temperature range of nitrification in soil is 30-40℃, while in pure cultures of 25-35℃, 6.6-8.0 is the best pH range. 6-8 is a denitrification the optimum pH, optimum temperature range is 20-30℃. In the test set constant temperature is 25℃, pH=7.3.

Material: $(NH_4)_2SO_4$(0.05mol/L), K_2HPO_4(0.2mol/L),KH_2PO_4(0.2mol/L), according to the volume ratio of 30:7:3 preparation, C/N is about 3:1. and pH=7.3.

Test Method： Two copies of the 100 g ceramic matrix in two of 250 mL glass flask, adding 100 concentration of mL was NH_4^+-N containing 100 mg/L medium, grade 1 (sample 2 (adsorption), microbial uptake of sample), all wrapped with cotton gauze plugging. Sterilization of 30min 1 bottles in the autoclave, removal and 2 bottles placed in the constant temperature box oscillation oscillation 48h, temperature 25℃, rotate speed is 150 r/min, every 6 hours for two water samples of supernatants of 10mL, 0.45μm membrane, the analysis of NO_3^--N content in filtrate, the results averaged. Each water sample with medium supplement. When the concentration of stable NO_3^--N in cultured supernatant, stop test.

Method: Ultraviolet Spectrophotometry **Formula**: $W1= (C_2-C_1) \times (V_1-V_2) \times k/ (t*m)$

W_1:NO_3^--N concentration, unit mass of filler in unit time of $mg.kg^{-1}.h^{-1}$; C_2 ,C_1: represent the mass concentration;NO_3^--N:6h mg/L ;V_1:the volume of culture medium, V_2:water volume packed samples, L; k: water coefficient; m :sample mass, g; t:time, h.

1.2.2 The Denitrification Reaction Test

Material:proportion of glucose ($C_6H_{12}O_6$) (0.02mol/L), KNO3 (0.03mol/L), K_2HPO_4 (0.2mol/L), KH_2PO_4 (0.2mol/L), according to the volume ratio of 10:30:7:3 preparation, C/N is about 3:1. and PH=7.3.

Test Method： Similar to the nitrification reaction test, the difference is the No.1 and No.2 bottle after bottle sterilization and sterilization of rubber stopper tightly and sealed bag, Placed in temperature is 25℃ constant temperature box in the oscillations of the 48 h .The remaining steps above.

Method: Ultraviolet Spectrophotometry **Formula**: $W_1= (C_1-C_2) \times (V_1+V_2) \times k/ (t * m)$

W_1:NO_3^--N concentration, consumption in the denitrification reaction unit in unit time and mass of $mg.kg^{-1}.h^{-1}$; the rest of the symbolic meaning.

1.3 The Amount of Nitrogen Absorption Plant

Material:Artificial wetland in the optimal operation parameters for 84 days, the influent from raw water, the following indexes of water mass.

Table 2 Experimental wastewater mass index

Wastewater quality indicators	pH	NH_4^+-N （mg/L）	TN （mg/L）	TP （mg/L）	DTP （mg/L）
Parameter	6.85-7.43	3.76	3.84	0.34	0.21

Test tank size: 0.8mx0.6mx0.6m;Canna:10 strains (2*5);In order to facilitate drainage, bottom along the direction of flow of 5 ‰ slope.

Test Method

Trial begins to choose has trained plant close to the size of the 3 plants, canna, washed with distilled water, dry, place each canna were divided into three parts for the stem, leaf, root, weighing record, and then placed in the filming for the 105 ℃ oven for 30 minutes, temperature to 60 ℃, 72 hours drying, and then weighing record, the three parts of canna separately after cut up by two grinding, through 80 mesh sieve, stay for chemical analysis. End of the test, randomly selected from the above three strains of canna in artificial wetland plant processing.

Method: TN: potassium persulfate oxidation ultraviolet spectrophotometry; Water and mass: electronic balance weighing method

Formula:P= (M2 * K2 * W2 M1 * K1 * W1)

P:all parts of Canna in growth running total absorption of nitrogen; M1, M2 test before and after the Canna mass; K1, K2 test before and after water coefficient. W1, W2 as the nitrogen content of Canna in vivo test before and after the.

Results and Discussion

2.1 Analysis of Ceramsite Isothermal Adsorption Test

Initial concentration of NH_4^+-N solution is 100mg/L, the concentration of NH_4^+-N decreased at first and then slowly increased.4h NH_4^+-N concentrations reached the lowest at NH_4^+-N , haydite on the maximum adsorption capacity, adsorption capacity of 0.032mg/g. After the start of the desorption occurs, 6h, analytic rate was 11.35%; 12h, analytical rate was 19.50%; 24h, 23.75%. 3H NO_3^--Nresolution for the lowest concentration, the ceramsite on NO_3^--N maximum adsorption capacity, adsorption capacity of 0.024mg/g.

2.2Nitrification and Denitrification Strength Test Analysis

2.2.1 Nitration Strength Test: Denitrification intensity on the use of NH_4^+-N variation before and after culture to approximate representation. In this experiment, the nitrification intensity can directly reflect the wetland system for NH_4^+-N removal capacity.Along with the extension of time, the filler adsorption desorption equilibrium system. 6h, microbial nitrification intensity of 1.354mg.h-1.kg-1; 12h, the nitrification intensity of 0.722mg.h-1.kg-1; 24h, the nitrification intensity of 0.633mg.h-1.kg-1. The nitrification intensity of 0.750mg.h-1.kg-1. Because of the influence of nitrification by dissolved oxygen is larger, with increasing filler depth, dissolved oxygen reduction, nitrification intensity will decline.

2.2.2 The Denitrification Reaction Strength Test: Denitrification intensity on the use of NO_3^--N variation before and after culture to approximate representation. In this experiment, the TN of the influent is NH_4^+-Nand the concentration of NO_3^--N and test, and denitrification intensity to a certain extent, reflect the ability of nitrogen removal and wetland system.Along with the extension of time, the filler adsorption desorption equilibrium system. 6h, microbial denitrification intensity of 0.930mg.h-1.kg-1; 12h, denitrification intensity of 1.030mg.h-1.kg-1; 24h, denitrification intensity of 1.210mg.h-1.kg-1. The average denitrification intensity of 1.090mg.h-1.kg-1. Because of the influence of denitrification intensity by the dissolved oxygen is larger, with increasing filler depth, dissolved oxygen reduction, denitrification intensity increased.

2.3 Analysis of Plant Nitrogen Absorption Test

Before and after the test of Canna physiological characteristics all have a change within a certain range, after the test of Canna plant weight is 2.85 times before the test, and studies have shown that plants absorb changes in plant growth depends to a great extent, the mass of unit plant nitrogen content with plant growth changes very little, Canna in the growth process in the water in which was a slight increase. Therefore be Canna Roots, stems, leaves the average nitrogen content respectively increase 7.73%, 12.4%, 9.92%.

Summary

1.Spherical light ceramsite absorption of NH_4^+-N solution of 100mg/L reached the maximum at 4h, the saturated adsorption amount was 0.032mg/g, equilibrium desorption rate as 34.5%. Spherical light ceramsite absorption of NO_3^--N solution of 100mg/L reached the maximum at 3h, the saturated

adsorption capacity is 0.024mg/g, desorption rate of 37.3%. Equilibrium adsorption strength increased first then decreased and finally tends to the balance trend. Spherical light ceramsite as adsorption intensity, microbial adhesion, equilibrium analytical rate is low, therefore suitable as filler of artificial wetland system.

2.In vertical flow constructed wetland, spherical light ceramsite as filler, the average nitrification strength microorganism was $0.75mg.h^{-1}.kg^{-1}$, average denitrification intensity of $1.09mg.h^{-1}.kg^{-1}$. During the operation the condition, total nitrogen about 2079.41g.

3. Artificial wetland plant cannas unit weight of root, stem and leaf nitrogen content were increased by 7.73%, 7.73% and 9.92% per plant cannas average of 1.189 g, nitrogen absorption during the running period of 10 plants absorb about 11.89 g. Canna on nitrogen absorption effect is better .

Keywords: post-weld heat treatment, CGHAZ, fracture, temper embrittlement, intergranular fracture.

Abstract. The effect of post-weld heat treatment (PWHT) on carbide precipitation and impact properties of coarse-grained heat-affected zone (CGHAZ) of Q690 Steel was studied in this paper. Carbide particles precipitated primarily at prior austenite grain boundaries and martensitic lath boundaries. When the PWHT temperature is 520–570 °C, temper embrittlement occurs. This temperature range is also where the number of carbide particles per unit area at grain boundaries reaches its maximum. The high number of particles per unit area increases the rate of crack initiation at grain boundaries under rapid loading; linking of microcracks along grain boundaries which are already weakened by impurity segregation results in TE and intergranular fracture.

1. Introduction

The heat-affected zone (HAZ) of high-strength low-alloy steels develops poor mechanical properties owing to the thermal cycling experienced during welding; the CGHAZ, whose microstructure typically consists of martensite or bainite (when the heat input is high) is generally considered to be the weakest section [1,2]. Post-weld heat treatment (PWHT) can improve the microstructure and mechanical properties of the CGHAZ; this happens through several processes, including tempering of martensite, decomposition of martensite-austenite (M-A) constituent and elimination of residual stresses [3,4]. Although there have been many industry standards and fabrication codes which attempt to provide PWHT parameters such as duration and temperature, the main purpose of these codes are to eliminate residual stresses; the recommended parameters usually cover a wide range, and must be tailored for a specific steel.

Generally, precipitation of carbide lowers the toughness of high-strength steel, depending on the morphology, distribution and size of the precipitates [5,6]. The loss in toughness caused by carbide is associated with its effect on initiation of fracture[7,8]. To reduce or eliminate welding residual stresses and avoid thermal stresses induced by uneven temperature distribution during cooling, PWHT is often conducted under conditions of high temperature and slow cooling. However, temper embrittlement (TE) usually occurs when as-quenched martensite is slowly cooled through or isothermally heated in the temperature range of 400–600 °C [9]. It is now well established that TE is caused mainly by the segregation and build-up of residual impurity elements (e.g. S, P, Sb, Sn) at grain boundaries [10]. The effect of carbide on TE and the accompanying intergranular fracture mode still needs to be identified; Morozov et al. reported that the temper embrittlement of Cr-Mo-V steel during tempering is affected mainly by carbide formation [11]. The temper embrittlement and intergranular fracture of high carbon carburized steel is also found to be related to cementite formation at austenite grain boundaries during quenching [12]. Details of the mechanisms are not yet understood. The purpose of this paper is to clarify in detail the effect of carbide on TE, and to propose a reasonable PWHT process.

2. Material and experiments

Commercial Q690 steel of 808 MPa yield strength was used. The compositions are given in Table 1. The welding tests were conducted using a YD-500 arc welding machine and carried out by means of multi-layer and multi-pass welding. The welding parameters were: welding current, 230 A, arc voltage, 24.5 V, welding speed, 1.75 mm·s-1. The PWHT included tempering samples at different temperatures (420, 470, 520, 570 or 620 °C) for 1.5 h, followed by cooling in the furnace to 200°C. Microstructures were etched using 3% nital or LePera etchant (50 ml of 1% $Na_2S_2O_5$ aqueous solution+50 ml picric acid 4% in ethanol) and examined by optical microscopy and SEM. Charpy specimens (10×10×55 mm) were etched prior to notching to facilitate accurate placement of the V notch tip within the CGHAZ. Charpy impact tests were performed on a Charpy impact tester (Model: JB30B, Jinan, China) at a temperature of −20 °C. The fracture surfaces of the Charpy specimens were also observed by SEM.

Table 1 Chemical composition of experimental steel (mass fraction, %)

C	Si	Mn	P	S	Cr	Ni	Mo	Nb+V+Ti	B	Alt	Fe

3. Experimental results

Microstructures of the CGHAZ, as-welded and after PWHT, are shown in Fig. 1. The CGHAZ consists primarily of lath martensite with a small amount of carbides situated at prior austenite grain boundaries and martensitic lath boundaries (Fig. 1a); this is related to the effect of auto-tempering since the carbon content of the steel is low. No significant changes were observed in the morphology of martensitic laths after PWHT at any temperature (Fig. 1b–d). Fig. 1c shows numerous small carbide particles, which have reprecipitated along grain and lath boundaries at 520 °C; the number of these particles per unit area is greatest for this tempering temperature. At 620 °C, particle coarsening occurs and there are fewer particles (Fig. 1d).

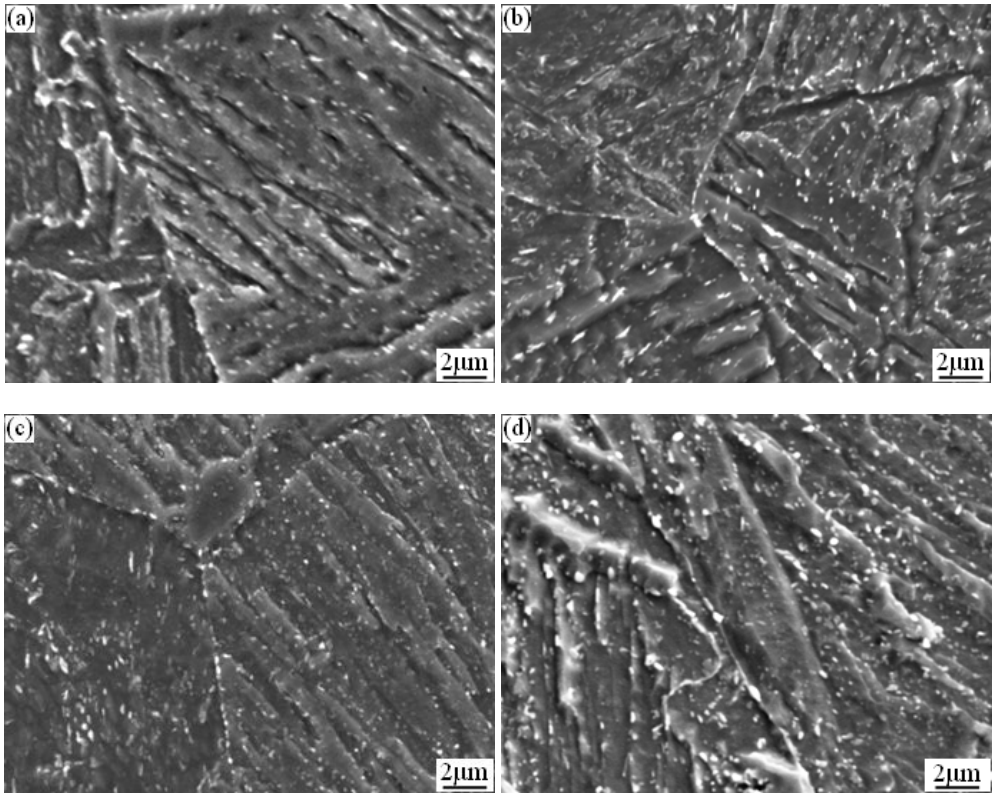

Fig. 1 SEM micrographs of CGHAZ tempered at different temperatures: (a) as-welded, (b) 420 °C,(c) 520 °C, (d) 620 °C

During multipass welding, the CGHAZ formed by the first heating cycle is modified by the subsequent thermal cycles, which form localized and discontinuous zones. It is often found that the intercritically reheated coarse-grained heat-affected zone (IC CGHAZ) displays the lowest toughness [13]. Despite its small size the IC CGHAZ may have an effect on toughness, so the microstructure evolution after PWHT was observed (Fig. 2). As can be seen from Fig. 1a and Fig. 2a, the main difference between the CGHAZ and IC CGHAZ is the presence of a “necklace” structure of blocky particles located at prior austenite grain boundaries. According to the interpretation of the formation mechanism of MA constituent (high-carbon martensite with some retained austenite) by Biss [14], these blocky particles are a mixture of MA constituent and a small amount of bainite. When etched with LePera etchant, the MA constituent (white color) can be distinguished [15] (Fig. 2b). Fig.2b–d shows that the MA constituent decomposes gradually with increasing temperature; by 520 °C it has decomposed completely.

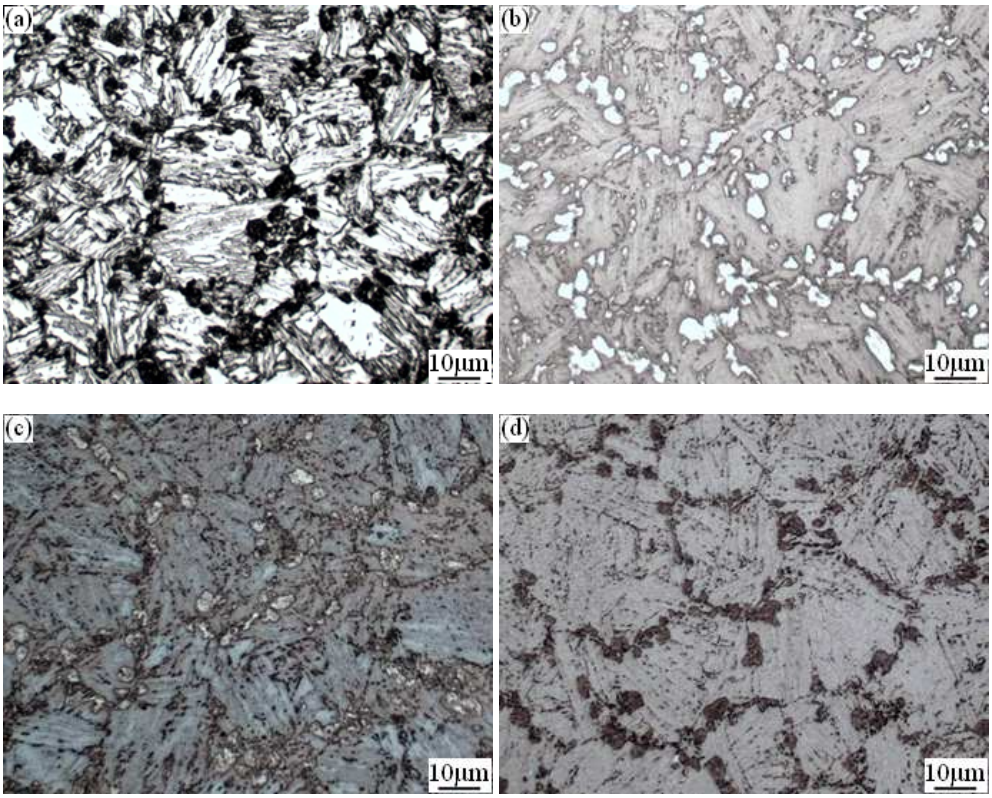

Fig. 2 Optical micrographs of IC CGHAZ tempered at different temperatures: (a, b) as-welded, (c) 420 °C, (d) 520 °C

Table 2 shows the the testing results of Charpy impact energy at different tempering temperature. Tempering the steels at 420°C and 470°C increased the impact energy. However, an abrupt decrease in impact energy was seen at 520 °C and 570 °C, before another increase at 620 °C. The minimum energy at 520 °C to 570 °C

Table 2 The Charpy impact energy of CGHAZ at different tempering temperature.

Temperature/ °C	—	420	470	520	570	620
Charpy impact energy/ J	92.1	143.2	158.1	69.0	55.1	162.5

Fig. 3 shows the fracture surfaces of the CGHAZ, as-welded and after PWHT. The fracture appearance of the as-welded CGHAZ was mostly quasi-cleavage, with many ridges (Fig. 3a). Tempering the specimen at 420 °C changed the fracture surface to show predominately ductile microvoid coalescence, indicating a ductile fracture mechanism. The fracture surface of the sample tempered at 520 °C contains many smooth intergranular facets; this is because the fracture mode has begun to change to brittle intergranular fracture. As the tempering temperature increases to 620 °C, the fracture surface again shows similar features to those observed at 420 °C.

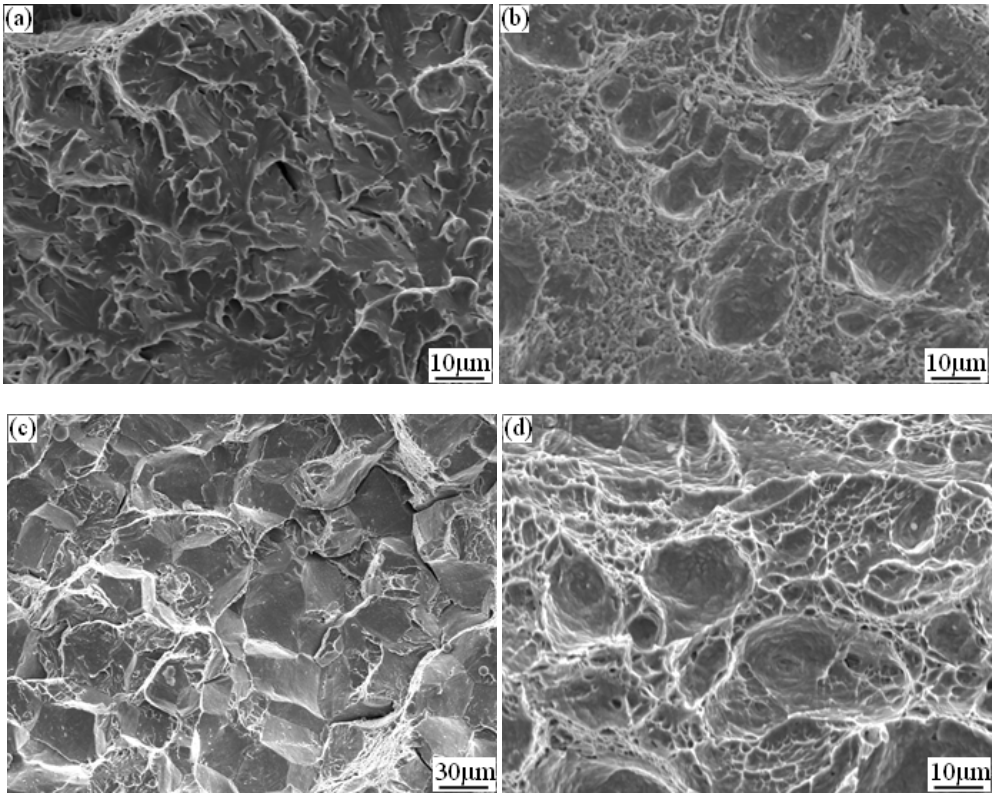

Fig. 3 Fracture surface appearances (SEM) of CGHAZ tempered at different temperatures: (a) as-welded, (b) 420 °C, (c) 520 °C, (d) 620 °C

4. Discussion

The IC CGHAZ is often described as a local brittle zone caused by the presence of MA constituents containing mainly high carbon martensite, which has a twin structure and a hard, brittle nature [16]. On loading, the coarse MA particles readily crack or debond from the matrix, and act as the principal crack-initiation sites because of stress concentration at the MA/matrix interface [17, 18]. The cracks propagate initially within the IC CCHAZ, and further propagation of cracks into the surrounding matrix results in quasi-cleavage (see Fig. 3a). Meanwhile, the initiation and propagation of cracks will be accelerated because of the overlap of applied stresses and residual welding stresses caused by nonuniform thermal expansions and solidifications during the welding processes. After tempering, decomposition of MA constituent and reduction or elimination of residual stresses enhance the impact toughness. The fracture mode changes to ductile microvoid coalescence (see Fig. 3b, d).

Carbides at grain boundaries usually lower toughness, because cracks are initiated when piled-up groups of dislocations meet carbides. When TM and intergranular fracture occur, the amount of carbides is expected to play a role. Previous studies pointed out that, in addition to microstructures, the decrease in impact toughness and onset of intergranular fracture are affected by external conditions such as test temperature (which influences the toughness of the matrix) and loading rate [19]. Research by Ronald showed that no embrittlement-associated fall in toughness was observed using samples tested in slow bending [20]. Under impact loading conditions, to relieve the substantial potential energies gained rapidly, more dislocations form inside a grain, and glide on multiple slip planes in more activated slip systems. Since there are more carbide particles at grain boundaries in the temperature range where TE occurs, massive microcracks emerge at the very beginning of loading. The high number of particles means that there are many microcracks, and these microcracks can become linked during further loading along the grain boundaries, which are already weakened by the impurity segregation. As a result, a sudden decrease in impact energy occurs, accompanied by the change in fracture mechanism to intergranular fracture.

5. Conclusions

(1) When the PWHT is performed at 420 °C, 470 °C, or 620 °C, the impact toughness of CGHAZ can be improved, mostly as a result of the decomposition of MA constituents. At 520 °C and 570 °C, temper embrittlement and intergranular fracture occur, which appear to be associated with the combined effects of precipitation of carbides and the prior segregation of impurities at grain boundaries. Therefore PWHT around 520–570 °C should be avoided.

(2) The carbides nucleate primarily at prior austenite grain boundaries and martensitic lath boundaries. In the temperature range where temper embrittlement occurs, the number of carbide particles per unit area reaches a maximum.

(3) Carbides at grain boundaries are associated with massive microcracks under rapid loading in the temperature range of temper embrittlement; the linking of microcracks along grain boundaries already weakened by impurity segregation results in temper embrittlement and intergranular fracture.

Keywords: Twin screw extruder, vane extruder, polypropylene, sisal fiber, orientation.

Abstract. The polypropylene/sisal fiber composites were prepared by twin screw extruder and vane extruder, respectively. The tensile test specimens perpendicular to the extrusion direction and parallel to the extrusion direction were prepared from the extruded composites, respectively. SEM observation showed that fiber orientation of sisal fiber in the composites was not obvious when the content of sisal fiber not more than 15wt%. When the content of sisal fiber was 15wt%, the ability to orientate of sisal fiber in the composite prepared by vane extruder was better than that of in the composite prepared by twin screw extruder, which the fiber orientation of sisal fiber was obvious along the extrusion direction in the composite. Tensile tests showed that the tensile properties of the composite parallel to the extrusion direction with 15wt% sisal fiber prepared by vane extruder were the best compared with other composites in this work. The results illustrated that the orientation of sisal fiber in the composites was beneficial to the improvement of the tensile properties of the composites.

Introduction

In recent years, the research and application of adding natural fibers to plastics as filling material to prepare for fiber reinforced composites have received extensive concern [1-4]. Sisal fiber (SF) as one kind of various fibers with high break strength has been widely used for reinforcing material [5-7]. Polypropylene (PP) is one of the most being in common use polymer materials with good physicochemical properties. Using sisal fiber to reinforce polypropylene not only reduces the cost, but also combines the advantages of the two materials, which has been studied extensively [8-10].

In the present, melt blending method was usually used to prepare for natural fiber/polymer composite, which is mainly carried out by the screw extruder based on shear force field. During the process, fibers are easy to degrade or suffer some damages because of the strong shear force of screws and the strong friction between the screw and the barrel [11]. Different from shear force field, in elongation force field, velocity gradient has the same direction with materials flow direction, which is helpful for the orientation and dispersion of fibers. Some methods realized local applications of elongational deformation flow field in polymer processing with high efficiency but low consumption [12-16]. Qu J.P. et al. invented a vane extruder based on elongational deformation, which is helpful for the orientation and dispersion of fibers in the composites [11,11-19].

In this study, the PP/SF composites were prepared by twin screw extruder and vane extruder respectively. The tensile test specimens perpendicular to the extrusion direction and parallel to the extrusion direction were prepared from the extruded composites, respectively. Tensile tests and SEM morphological observation of the specimens were carried out. The orientation of SF in the composites prepared by the two extruders was characterized. The tensile properties and the relationship between the orientation of SF and tensile properties were also investigated in this work.

Experimental

Materials and Equipment. Polypropylene (N-Z30S) with a density of 0.9 g/cm^3 and MFI (190°C, 2.16kg) 25 g/10 min was supplied by China Petroleum & Chemical Co., China; Sisal fiber was supplied by Dongfang Sisal Co., China.

The vane extruder (VE) used in this work is self-designed. Figure 1 shows the schematic diagram of the vane extruder. The vane extruder is novel equipment for polymer processing, which comprised of several vane plasticating and conveying unit. The vane extruder extrusion completes a plasticating and positive displacement conveying process based on elongational rheology in a short thermo-mechanical history [20]. The temperature profile from hopper to die of VE was determined by 170-180-185-180°C. The twin screw extruder (TSE) used in this work is a traditional extruder, the screw diameter is 50, the length to diameter ratio is 38. The temperature profile from hopper to die of TSE was determined by 170-175-180-180-185-185-180-180°C.

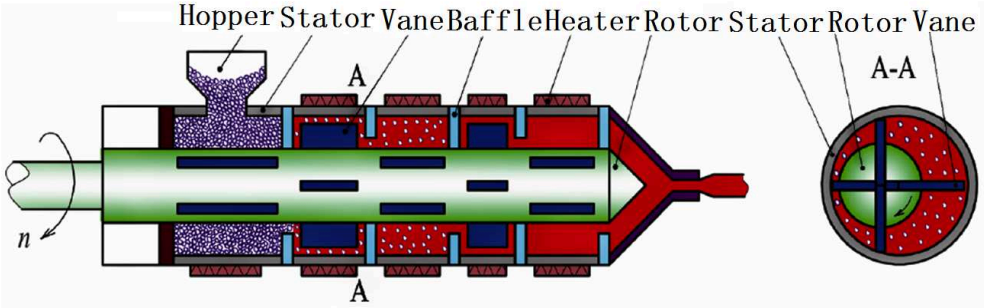

Fig.1 The schematic diagram of vane extruder

Preparation and Characterization. The dried SF was cut to about 10mm and blended with PP according to the mass ratios (PP/SF, 95/5, 90/10, 85/15) in a mixing machine. The mixtures of PP/SF were then fed into the VE and TSE for extrusion processing with a rotation speed of 60r/min. Subsequently, the dried composite strips were compressed into composite sheets with the thickness of 1mm according to the extrusion direction orderly in the mould. The composites were kept in the mould under 190°C, 10MPa for 6min and then cooled to room temperature. The composites sheets were then cut perpendicular to the extrusion direction and parallel to the extrusion direction to prepare for the tensile specimens.

The tensile tests of the composites were carried out using an Instron Universal Testing Machine (model 5566, USA) with a crosshead speed of 2 mm/min. All of the data are the average from six determinations. The brittle fractured surface and the tensile test fractured surface of the PP/SF composites were coated with Au for SEM (S-3700N, Hitachi, Japan) observation.

Results and Discussion

Figure 2 shows the brittle fractured surface of PP/SF composites (with 15% SF) prepared by TSE and VE. In Fig. 2, TSE (a) and VE (a) show the fractured surface perpendicular to the extrusion direction, TSE (b) and VE (b) show the fractured surface parallel to the extrusion direction. It can be seen from TSE (a) and TSE (b) that there is no remarkable SF orientation in PP/SF composite. On the surface in TSE (a), there are fibers and grooves parallel to the surface, and there are also fibers and holes perpendicular to the surface. In TSE (b), the morphology is similar to TSE (a). The result indicates that the SF in the PP/SF composites prepared by TSE in our experiment oriented along the extrusion direction was not obvious and the ability of orientation of SF was weak. For the PP/SF composites prepared by VE, it can be seen from VE (a) and VE (b) that the orientation of SF in the composite was obvious. In VE (a), there are fibers and holes perpendicular to the fractured surface. In VE (b), there are fibers and grooves parallel to the fractured surface. The result indicates that the SF in the PP/SF composites prepared by VE in our experiment oriented along the extrusion direction was obvious and the ability of orientation of SF was strong.

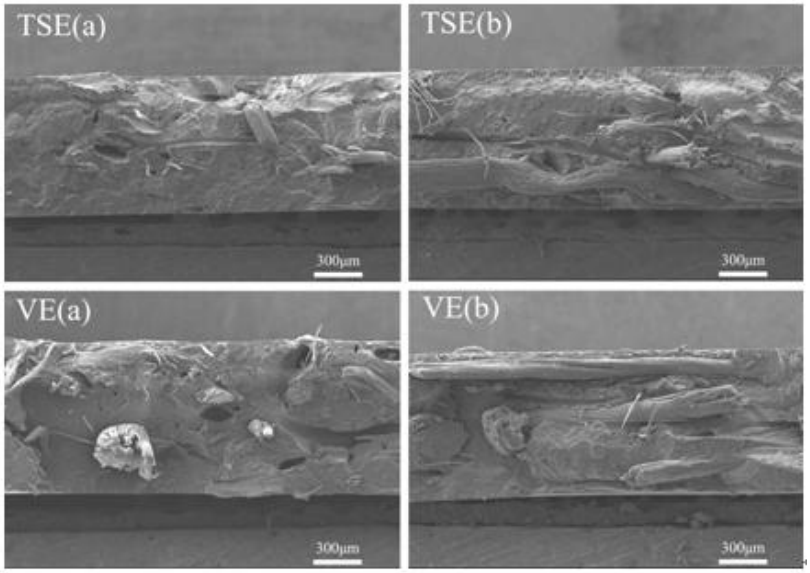

Fig.2 SEM of brittle fractured surface of PP/SF composites (with 15% SF) prepared by TSE and VE (a- perpendicular to the extrusion direction, b- parallel to the extrusion direction)

The tensile test fractured surface of PP/SF composites (with 15% SF) prepared by TSE and VE was observed by SEM in Fig. 3. In Fig. 3, TSE (c) and VE (c) show the fractured surface perpendicular to the extrusion direction, TSE (d) and VE (d) show the fractured surface parallel to the extrusion direction. In our tests, the tensile tests direction was the same with extrusion direction. It is similar to the observation in Fig. 2. In Fig. 3, on the tensile fractured surface of PP/SF composite prepared by TSE, there are fibers and grooves parallel to the surface, and there are also fibers and holes perpendicular to the surface (See TSE (c) and (d)). For the composite prepared by VE, it can be seen from VE (c) and VE (d) that along the extrusion direction, the SF in the composite oriented obviously (See VE(c) and (d)). Combined with the fiber orientation character in Fig. 2 and Fig. 3, the results indicate that the VE processing of the PP/SF composite is more conducive to improve the SF orientation along the extrusion direction compared with the TSE processing in our experiment condition.

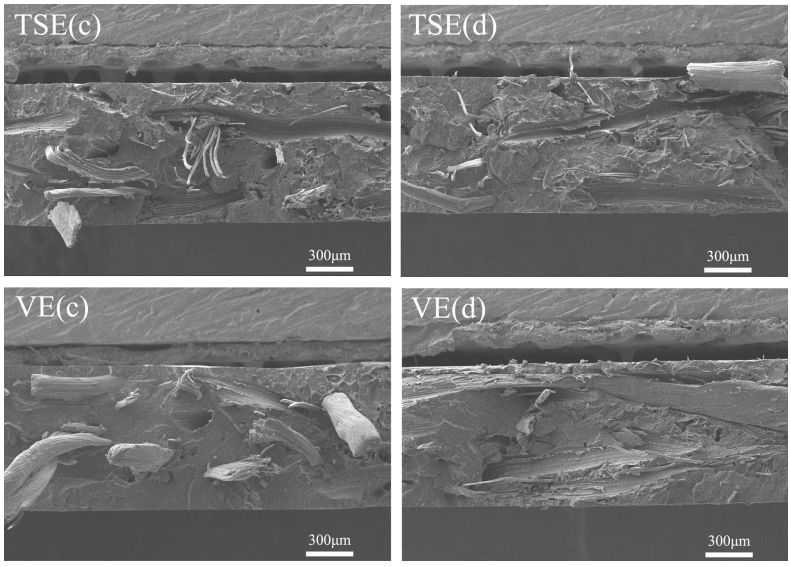

Fig.3 SEM of tensile test fractured surface of PP/SF composites (with 15% SF) prepared by TSE and VE (a- perpendicular to the extrusion direction, b- parallel to the extrusion direction)

In order to investigate the interfacial properties of SF and PP matrix in the PP/SF composites, SEM of enlarged scale of tensile test fractured surface of PP/SF composites (with 15% SF) prepared by TSE and VE were observed in Fig. 4. It can be seen that the interfacial compatibility between PP matrix and SF was bad. Not only processing by TSE but also by VE, there is obvious gap between PP matrix and SF. Moreover, it can be seen from Fig. 4 that there are grooves formed from the fiber

pull-out from PP matrix during the tensile test process. Compared with TSE processing, the grooves in the composite prepared by VE was much coarser. The result indicates that VE processing has a better squeezing action than TSE processing on the PP/SF composites, which is beneficial to improve the interfacial properties and mechanical properties of the composites.

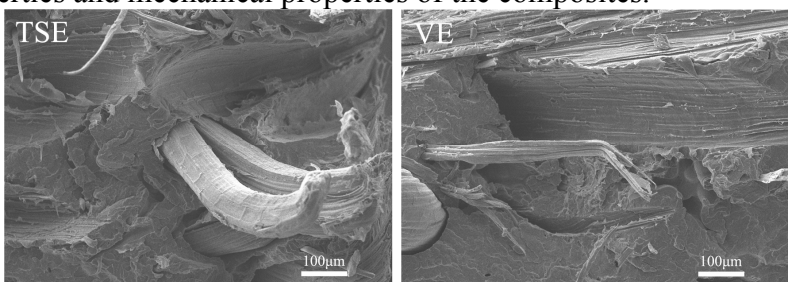

Fig.4 SEM with enlarged scale of tensile test fractured surface of PP/SF composites (with 15% SF) prepared by TSE and VE

The tensile properties of PP/SF composites prepared by TSE were shown in Table 1. It can be seen that both perpendicular to the extrusion direction and parallel to the extrusion direction, the tensile strength, tensile modulus and elongation at break of PP/SF composites with different SF content decreased significantly compared with pure PP. This mainly because that there are a lot of polar hydroxyl groups in SF, while polypropylene chains are nonpolar, the interfacial compatibility between PP matrix and SF is poor [21]. The weak interface interaction between SF and PP matrix cannot transfer stress and energy effectively under tensile stress. The tensile property of the composites then decreased. When the SF content was 5wt%, the tensile strength and elongation at break of the composite perpendicular to the extrusion direction and parallel to the extrusion direction were similar, but the tensile modulus was very different. When the SF content was 10wt%, the difference of tensile strength of the composite between perpendicular to the extrusion direction and parallel to the extrusion direction was increased, while the differences of tensile modulus and elongation at break were little. When the SF content was 15wt%, the differences of tensile strength, tensile modulus and elongation at break of the composite between perpendicular to the extrusion direction and parallel to the extrusion direction were little. For the three composites with different SF content, the tensile properties of the composites perpendicular to the extrusion direction and parallel to the extrusion direction have little change. As the TSE processing is based on shear force flow, the orientation of SF in the composite prepared by TSE was poor.

Table1 Tensile properties of PP/SF composites prepared by TSE

Tensile property	PP	PP/5wt% SF		PP/10wt% SF		PP/15wt% SF	
		PL[d]	PD[e]	PL	PD	PL	PD
TS[a] (MPa)	31.66	24.88	24.50	27.86	24.31	23.19	21.97
TM[b] (MPa)	261.11	209.50	229.90	205.08	211.39	217.90	205.11
EAB[c] (%)	15.48	11.36	11.17	10.88	11.12	12.48	11.71

Table2 Tensile properties of PP/SF composites prepared by VE

Tensile property	PP	PP/5wt% SF		PP/10wt% SF		PP/15wt% SF	
		PL[d]	PD[e]	PL	PD	PL	PD
TS[a] (MPa)	33.33	27.04	26.72	26.28	23.42	28.71	19.20
TM[b] (MPa)	275.74	211.08	209.69	213.90	190.51	259.71	193.26
EAB[c] (%)	16.29	12.67	12.31	11.43	10.36	13.2	10.22

[a] TS refers to tensile strength, [b] TM refers to tensile modulus, [c] EAB refers to elongation at break, [d] PL refers to perpendicular to the extrusion direction, [e] PD refers to parallel to the extrusion direction

Table 2 shows the tensile properties of PP/SF composites prepared by VE. Similar to the composites processed by TSE, the tensile properties of PP/SF composites prepared by VE was decreased significantly compared with pure PP. It is due to the poor interfacial compatibility between PP matrix and SF. When the SF content was 5wt%, the tensile strength, tensile modulus and elongation at break of the composites perpendicular to the extrusion direction and parallel to the

extrusion direction were closed to each other. This indicates that in our experiment, the SF orientation in the composite with low SF content was poor. With the SF content increase, the difference of tensile strength, tensile modulus and elongation at break of the composites perpendicular to the extrusion direction and parallel to the extrusion direction became obvious. Compared with the composite with 5wt% SF and 10wt% SF, the tensile strength, tensile modulus and elongation at break of the composite parallel to the extrusion direction were increased when the SF content was 15wt%. For the composite perpendicular to the extrusion direction, the tensile properties were decreased compared with the composite with 5wt% SF and 10wt% SF. This may due to that with the increasing content of SF, the orientation of SF in the composite was easier and obvious, which increased the tensile properties of the composite parallel to the extrusion direction but decreased the tensile properties of the composite perpendicular to the extrusion direction. When the SF content was 15wt%, as the VE processing is based on elongation force field, the SF in the composite along the extrusion direction was easy to orient under elongation force. The orientation of SF in the composite with 15wt% SF can be seen in Fig. 2 and Fig. 3. As a result, the tensile properties of the composite parallel to the extrusion direction were the best.

Compared the TSE processing and VE processing, the comprehensive tensile properties of the composite parallel to the extrusion direction prepared by VE were better than that by TSE. On the one hand, the thermo-mechanical history of VE processing is short; the materials are not easy to degrade. For the TSE processing, the materials are easy to degrade. In our experiment, the color of the composite prepared by TSE was yellow and darker. It is due to the degradation of SF in the composite. On the other hand, the orientation of SF in the composite prepared by VE was much easier than that by TSE. Especially, when the SF content was 15wt%, the tensile strength of the composite parallel to the extrusion direction prepared by VE was greater than that by TSE. The result indicates that VE offers advantages than TSE on processing fiber reinforced polymer composites.

Summary

The PP/SF composites (SF content, 5wt%-15wt%) were prepared by TSE and VE, respectively. The orientation of SF in the composite prepared by VE was much easier than that prepared by TSE. When the SF content was 15wt%, the orientation of SF in the composite prepared by VE was obvious. The tensile properties of the PP/SF composites with 15wt% SF parallel to the extrusion direction prepared by VE were the best of all the composites in this work. The orientation of SF in the composites was beneficial to improve the tensile properties of the composites in the orientation direction.

Keywords: PBS; Carbon fiber; Mechanical properties.

Abstract. Chopped carbon fiber (CF) reinforced PBS/CF composites were prepared by twin-screw extrusion processing. The effect of adding a certain quantity of CF in composites on the tensile, flexural and impact properties have been investigated. The results indicated that the tensile properties, flexural properties and impact properties of the PBS/CF composites were first improved and then decreased with the increase of the content of CF.

1. Introduction

Composites enhanced with short fiber have been receiving great attention in recent years [1]. PBS is a kind of completely biodegradable plastics, possesses good melt processability, biocompatibility, good thermal stability and high toughness related to its low glass transition, which is widely used in packaging materials, hygienic products, agricultural film and other fields [2, 3]. In order to widen its applications, the physical properties of PBS need to be improved by addition of fibers. Nowadays, the reinforcing materials in polymer composites are typically carbon fibers (CF). Carbon fiber (CF) is a kind of non-metallic materials. Carbon fibers have become very important as a kind of reinforcement for polymeric composites over the last 40 years because of their high strength, high modulus, good electrical conductivity, low density, strong ability to adapt environment and good corrosion resistance to chemicals [4, 5]. The objectives of this study are to fabricate PBS/CF composites and to investigate the effects of the carbon fiber content on the mechanical properties of the composites. In this paper, the performance of the composites are discussed in terms of the tensile, flexural and impact properties.

2. Experimental

2.1 Materials

Poly (butylene succinate) (PBS) with a density of 0.91 $g.cm^{-3}$ and MI of 4.5g/10 min (130°C, BIONOLLE 1903MD) was provided by Showa Co. Ltd, Japan. The melting temperature of the PBS was about 120°C. Its tensile strength was 40MPa, with impact strength 6KJ/m^{-2}.

The carbon fiber (HTS-50PAN) used was also a commercial product (TOHO Products Co. Ltd, Japan) with an average diameter of 7um and an average length of 2～12mm. Its density was approximately 1.76 $g.cm^{-3}$. Its tensile strength was 3.7GPa, tensile modulus is 230GPa.

2.2 Composites preparation

The pure PBS was dried in an oven at 50°C for 8 hours. Then the carbon fibers were put in the chamber of a stove for 10 min and oxidized at 450°C. The carbon fibers mass fraction were 1%, 2%, 3%, 4%, 5%. Then the carbon fibers were directly mixed with the PBS in a high-speed mixer for around 15 min to prepare PBS/CF composites. For the purpose of comparison, pure PBS was also

melt blended under similar processing conditions in the mixer. In the first step the PBS/CF composites were homogenized in the twin-screw extruder. The mixture was cooled to room temperature and cut to the granules again. Then the samples were hot pressed at 130°C under 10 MPa for more than 6 min using a flat-plate sulfide machine to obtain composite sheets (4 mm thickness).

2.3 Characterization

The tensile properties of the PBS/CF composites were measured according to GB/T 1040—2006 using an Instron universal testing machine (model 5569) with the tensile speed 2 mm/min and the distance of 50 mm. The flexural testing was performed according to GB/T 1446—2006 standard at a cross-head speed of 2 mm/min. The impact strength according to GB/T 1843-2008. The average values of strength and modulus of each composites were obtained from five specimens. All the tests were performed at the room temperature, 50% relative humidity.

3. Results and discussion

3.1 Tensile property

Tensile properties of the PBS/CF composites reinforced by CF with different fiber content are represented in Figure 1. When the CF content reaches 2 wt%, the tensile strength and modulus reach

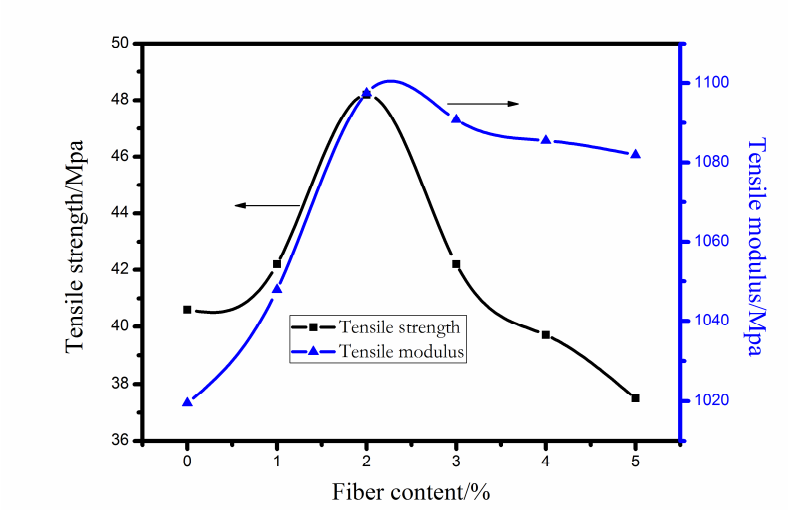

Fig. 1 The relationship of the tensile strength/modulus of composites and the content of carbon fiber

its maximum (48.1 MPa and 1097.5MPa), which is about 18.7% and 7.7% higher than that of pure PBS. The increase in tensile strength and modulus of PBS/CF is primarily attributed to the presence of carbon fiber, which allows a uniform stress distribution from continuous PBS matrix to dispersed fiber phase [6,7]. Tensile strength of composites subsequently decreases sharply along with the increase of fiber content. Tensile modulus then decreases slightly. The decrease in tensile strength and modulus may be due to the presence of so many fibers that cause more possibility of crack initiation, composite failure and fiber agglomeration within PBS/CF composites, leading to stress concentration and become a source of fracture, which have a negative impact on the tensile properties of the composites [2].

3.2 Flexural properties

It is observed that with the increase of fiber content from 0 to 3wt%, the flexural strength gradually increased, When the CF content reaches 3wt%, the flexural strength reaches its maximum (29.7MPa), which is about 9.14% higher than that of pure PBS. It is due to that the carbon fibers are coated effectively by the PBS, making carbon fiber evenly distributed in PBS. When the carbon fiber content increases continuously, the flexural strength of composites decreases. It is because it's easy to form fiber agglomeration, carbon fibers are not coated effectively by the PBS.

The flexural modulus goes up almost linearly with increasing fiber loading between 0 and 1wt %. When the fiber content is less than 4wt%, flexural modulus nearly remains constant. When the fiber content is greater than 4wt%, flexural modulus increases greatly. The modulus of the PBS/CF composites increases by 104.1% than the pure PBS with the fiber mass fraction reaches to 5%.

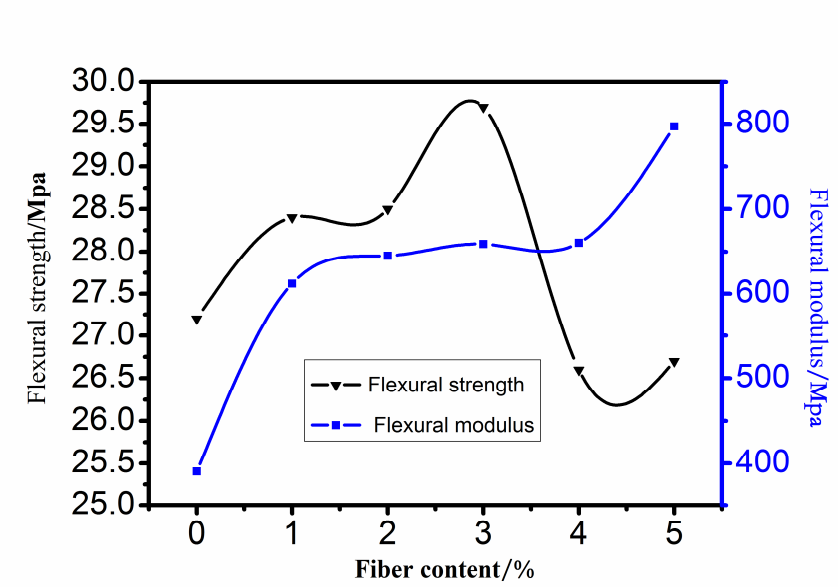

Fig.2 The relationship of the flexual strength/modulus of composites and the content of carbon fiber

3.3 Impact properties

The results of impact test on the PBS/CF composites are shown in Figure 3. The incorporation of

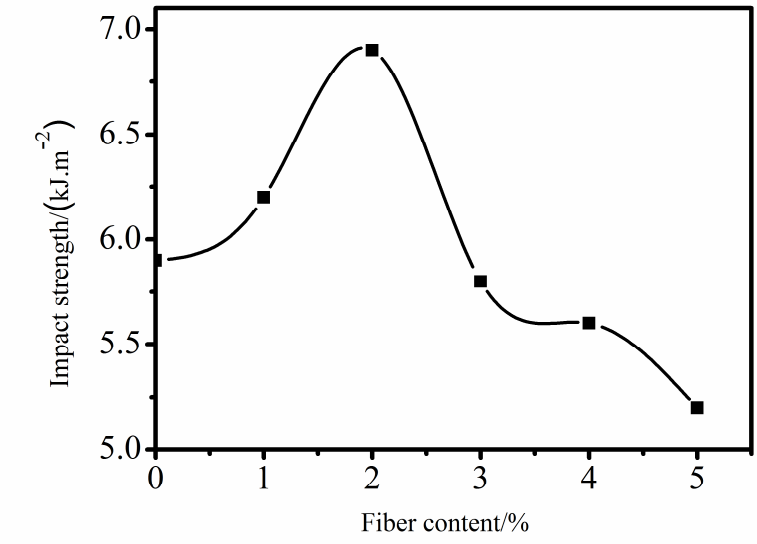

Fig.3 The relationship of the impact strength of composites and the content of carbon fiber

CF enhances impact strength of pure PBS. When the CF content reaches 2wt%, the impact strength reaches its maximum. The highest impact strength of the composites is 6.9kJ /m^{-2}, about 17% higher than that of the pure PBS. It is because PBS has good flexibility, which can deliver stress to make material not damaged under the external force. When the fiber content increases, low ductility of the fiber makes PBS constrainted, which decreases the impact strength.

4. Conclusion

In this study, the importance of carbon fibers in PBS/CF composites has been highlighted. It is observed that with the increase of fiber content from 0 to 2wt%, the tensile and impact strength are all gradually increased, and over 2wt% fiber content they are decreased or nearly remain constant. When the CF content reaches 3wt%, the flexural strength reaches its maximum (29.7MPa), which is about 9.14% higher than that of pure PBS. When the carbon fiber content increases, the flexural strength of composites decreases. The experimental results show that the mechanical strength or modulus of composites exits an optimum value at certain fiber content, which is 2wt% in this study.

Keywords: Optimization, landfill leachate, electrochemical oxidation process, surface methodology

Abstract. This experiment used the response surface methodology to optimize the treatment effect of electrochemical oxidation degradation of landfill leachate. The relationship between current intensity, aeration and pH value was studied by the response surface methodology. The analysis of quadratic polynomial regression and response surface was studied by Design expert7.0 software, and the model was optimized.

Introduction

Response surface method (RSM) is a comprehensive experimental design and mathematical modeling optimization method that evaluates the factors, which affects electrochemical degradation process and their interactions by establishing a continuous variable surface model, and determines the best level scope. It can decrease the time of test, finally achieve the goal of optimizing this response[1], and provide technical support for the electrochemical treatment of landfill leachate.

1 The experimental materials and methods

1.1 Waste water sources and water quality

This experiment adopts the landfill leachate collected from a landfill site of Shenyang. The main ingredients of the landfill leachate are shown in Table 1.

Table 1 .The main ingredients of the garbage leachate

main ingredients	units	contents
COD	mg/L	5000~20000
NH_3	mg/L	1000~1300
Cl^-	mg/L	500~4000
pH	1	7.5~8.5

1.2 Test equipment and methods

Instruments: WFJ2100 visible spectrophotometer; HI98127 written pH meter; FA1004N electronic balance; GSP-77-03 air compressor; WYJ - 302 B_2 DC regulated power supply.

Test method: COD fast airtight catalytic decomposition method (including photometry).

2The results and discussion

2.1 Box - Benhnken Design (BBD) Design of experiment

Selecting Box - Benhnken Design (BBD) experimental design methods, current intensity(X_1), aeration(X_2) and pH value(X_3) as the independent variables, COD removal rate as response variables(Y).By using the Design expert7.0 software to fit a quadratic polynomial regression and analyze the response surface. Factors coding table as shown in table 2.

Table 2 .Box - Benhnken Design coding table

Variable Coding value X_i	X_1	X_2	X_3
1	1.0	0.05	6.0
0	1.5	0.10	8.0
-1	2.0	0.15	10.0

Quadratic polynomial experience model: $Y=\beta_0+\sum_{i=1}^{3}\beta_i X_i+\sum_{i=1}^{j-1}\sum_{j=1}^{3}\beta_{ij}X_iX_j+\sum_{i=1}^{3}\beta_{ii}X_i^2$

In the formula: Y is predict response value; β_0, β_i, β_{ii} is offset, linear and second-order displacement coefficient; β_{ij} is interaction coefficient; X_i is independent coding value.

Through the Box - Benhnken Design (BBD), 12 IBFact point and 5 center point were concluded. According to the experiment scheme, the experimental result was achieved. The result is shown by table 3.

Table 3 .The RSM design and experimental result table

Std	Type	X_1(A)	X_2(m^3/h)	X_3	Y %
1	IBFact	1.00	0.05	8.00	29.13
2	IBFact	2.00	0.05	8.00	48.1
3	IBFact	1.00	0.15	8.00	24.73
4	IBFact	2.00	0.15	8.00	50.96

16	Center	1.50	0.10	8.00	49.20
17	Center	1.50	0.10	8.00	49.53

2.2 The result of the experiment and analysis

Fitting the experimental results by the Design expert7.0 software, the fitting model of the relationship between COD removal rate and the factors was shown as the quadratic polynomial:$Y=49.23+10.61X_1-0.80X_2-0.60X_3+1.81X_1X_2+0.51X_1X_3+0.080X_2X_3-0.77X_1^2-10.23X_2^2-6.77X_3^2$

The variance analysis of quadratic polynomial is shown by table 4.

Table 4 .The response surface quadratic polynomial model of variance analysis table

Sourse	Sum of Squares	df	Mean Square	F Value	p-value
Model	1600.46	9	177.83	175.64	<0.0001
X_1	899.73	1	899.73	888.67	<0.0001
X_2	5.18	1	5.18	5.12	0.0581
X_3	2.88	1	2.88	2.84	0.1355
X_1X_2	13.18	1	13.18	13.01	0.0087
X_1X_3	1.02	1	1.02	1.01	0.3489
X_2X_3	0.026	1	0.026	0.025	0.8781
X_1^2	2.49	1	2.49	2.46	0.1608
X_2^2	440.56	1	440.56	435.14	<0.0001
X_3^2	192.92	1	192.92	190.55	<0.0001
Residual	7.09	7	1.01		
Lack of fit	6.79	3	2.26	30.39	0.0033
Cor total	1607.55	16			

Statistical significance of quadratic polynomial model was expressed by F value, F shows that the more the value is, the more significant the model is. At the same time, when the P value is lower than 0.0500, it shows a significant model factors. When the P value is greater than 0.100, it shows no significance of the model factors. The F value of this experimental model is 175.64, which is more than 1. P value is less than 0.0001, which shows that the regression is significant. R^2 (decision coefficient of the model) is used to further test the effectiveness of the model. When R^2 value is between 0 and 1, closer to 1 indicates that the model can effectively reflect the experimental data, R^2 = 0.9956 means that 99.56% of changes of response surface can be predicted by this model. Adj - R^2 = 0.9899 (model adjust decision coefficient) showed that 98.99% of the response values change can be explained by the model, and there was a high model fitting and a little experiment error. As a result, this quadratic polynomial model can suitable real curved surface properly. The affection of various factors on COD removal rate can be ranged as: current intensity>aeration>pH value.

2.3 Analysis of two factor interaction effect

Dimension reduction analysis with the date in the table 3. To observe the interaction of current intensity, aeration rate and pH value on the removal rate of COD, analyzed by Design expert 7.0 software, the response surface and contour plots was showed from fig.2-7.

Fig.2 and fig.3 show that when the pH-value is 8, the effects between current intensity and aeration rate on COD removal rate. From Fig.2, the interaction between current intensity and aeration is obvious; the current intensity's effect on the removal rate of COD was significant. Because the aeration rate can accelerate the mass transfer rate of reaction, reduce the concentration polarization effects of the electrochemical reaction. Oxygen can produce strong oxidizing activity material such as: H_2O_2,·OH, OCl^- and so on. If aeration rate is excessive high, it's not conducive to pollutants adsorbed on the particle surface, causeing the COD removal rate decreased. The removal rate of COD increases rapidly, with increasing current intensity. However, If the current is too intensive, there will be no conducive to pollutant removal rate. The higher current intensity leads to the side reaction increase[2] . While the electrochemical energy consumption increases, the rate of current decreases. Under the condition of 0.1 m^3/h aeration and 2.0A current intensity, the removal rate of COD is favorable, about 59%.

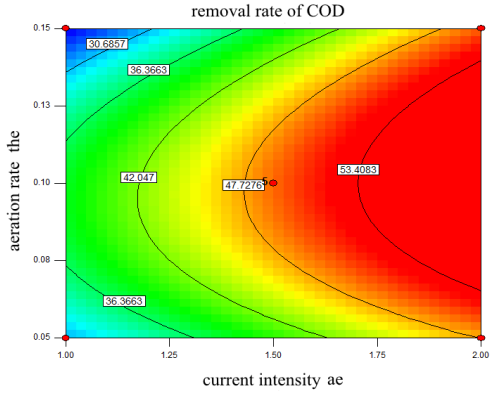

Fig.2.The current intensity - air contour map

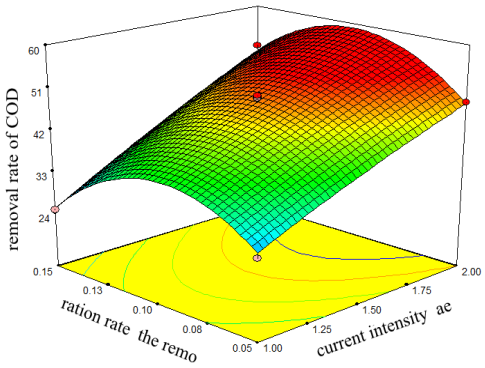

Fig.3.Current intensity - air three-dimensional stereogram

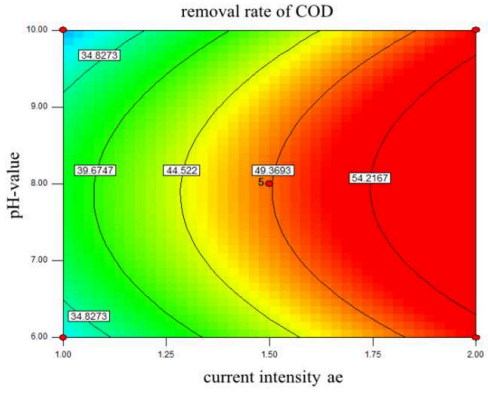

Fig. 4.The current intensity - pH contour map

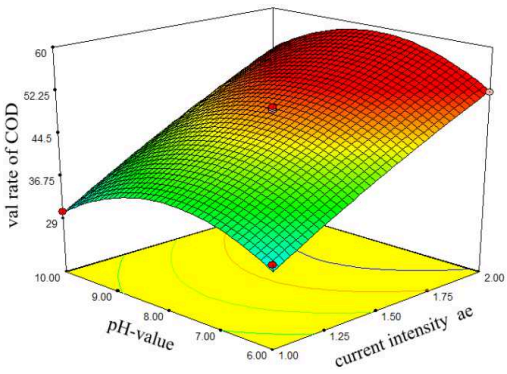

Fig. 5.Current intensity - pH 3 d stereogram

Fig.4 and fig.5 show that when the aeration rate is 0.1m^3/h, the effect between current intensity and pH value on the removal rate of COD. From Fig.4, the interaction of current intensity and the pH value is not obvious. When the pH value is certain, the removal rate of COD changes with the current. When the current is certain, the removal rate of COD increased and then decreased with the increasing pH value. When pH value is too low, the hydrogen evolution side reaction can occurred, the current efficiency was reduced, and part of organic matter may exist in flocculation morphology. It's insoluble in water and difficult to electrolysis[3]. When the pH value is too high, the final product may exist in the formation of carbonate and bicarbonate which are consumption of •OH[4].While the amount of OCl^- under weakly alkaline conditions better formed more , it causes decrease in COD removal. When the current is 2.0A, the pH value is 8, the removal rate of COD reached best value.

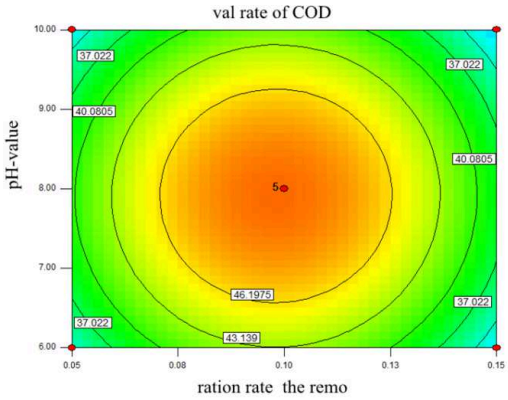

Fig. 6.Air - pH contour map

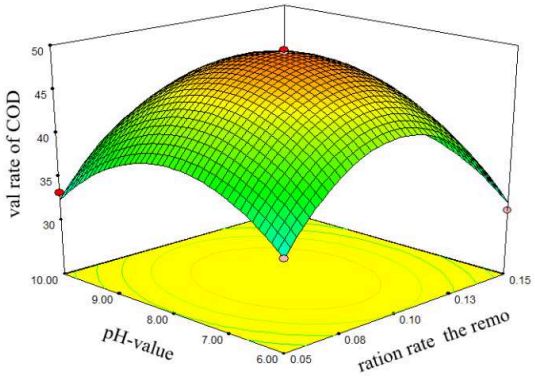

Fig. 7.Air - pH 3 d stereogram

Fig.6 and Fig.7 shows that the current intensity is 1.5A, the effect between aeration rate and pH value on the removal rate of COD. The removal rate of COD increased and then decreased with increasing aeration rate. However, with the change of pH value change is not obvious. When the aeration rate reaches 0.1m^3/h and pH value is about 8, the removal rate of COD is best, about 49%.Aeration rate and pH value have no significant interaction.

The interaction among the factors affects sequence with removal rate of COD is that the current - aeration > current -pH value > Aeration rate -pH value. The current intensity had significant influence on COD removal rate. Aeration and pH value had no significant effect on the properties.

3 Summary

The model shows that highest COD removal rate when the best current intensity, air and pH value were 1.94 A, 0.10 m^3/h and 8.35. Through The analysis of quadratic polynomial regression and response surface was showed, that the regression model to reach significance level, better fitting in study area, the precision, reliability and accuracy of the model are in the feasible range. The higher degree of agreement with the experimental results. Finally, we verified the parameters with the experiment, under the optimal conditions that the removal rate of COD was 57.69%, The relative error between the experimental values and the relative values is 0.1%. The model has guiding significance to the optimization of electrochemical oxidation process to landfill leachate with operation parameters and the effect of treatment.

Keywords: Silicon-based composite; hyperthermia resistance; resistance change; thermal load

Abstract. In order to research the resistance characteristic of silicon-based composite tiles under high temperature thermal load on aircraft during its reentry into the earth's atmosphere, the ordinary resistance measurements were comparatively discussed according to the operational environment of composite, two parallel electrodes probe test method was proposed, and the resistance test platform under high temperature thermal load was developed, by which the resistance characteristic of silicon-based composite tiles was continuous monitored under different thermal load. The result shows that: If the temperature is not higher than 600℃, the resistance will increase with the decrease of temperature until it reached the resistance value at room temperature; If the temperature is higher than 700℃, the resistance characteristic will be changed everlastingly; If the temperature is higher than 800℃, the resistance will be less than 1kΩ and will not change any more.

Introduction

Aircraft in its mission process will go through complicated meteorological environment such as the troposphere, the stratosphere and the thermosphere, among which the surface material will experience highly significant changes about speed, altitude and temperature[1]. In this process air containing with lots of atmosphere dust, ice and other friction particles will collide with aircraft and deposit electrostatic charge on the surface of the aircraft[2,3]. Especially in aircraft's reentry process, the surface of the material will collide with the particle heavily forming high temperature gas sheath called "blackout range". So triboelectrification situation is more complex and severe[4]. When the amount of aircraft's charge is so large that the aircraft electric field strength continues to increase to the threshold of air breakdown in the tip of wing or nose, strong electrostatic discharge will occur which radiate strong electromagnetic field[5,6], interrupting communication systems, navigation systems and other sensitive equipment[7]. It will pose a serious threat to flight safety.

To prevent damage to the aircraft caused by high temperature, thermal insulating material is used. But it may reduce the performance of communication systems, navigation systems and other sensitive equipment. For a long time, researchers tend to focus on materials insulating characteristics, but they concerns little about its electrical characteristics such as resistance characteristic[8]. Therefore, this paper proposed a series of experimental to research the typical insulating material's resistance characteristic under different thermal load.

Resistance characteristics test method

To evaluate the resistance characteristic of silicon-based composite, the ratio of the voltage U and the surface leakage current is called the surface resistance R_s, generally, and the ratio of the voltage U and the volume leakage current Iv is called the volume resistivity Rv. When silicon-based composite conducts current, surface resistivity and volume resistivity operate simultaneously. The two are connected in parallel relationship. Testing the surface resistance require excluding the influence of

volume resistivity. Testing the volume resistivity require excluding the influence of surface resistance at the same time. Using a three-electrode system testing can solve this problem.

However, the methods has a severely requirement on the material surface flatness. So it is essential to make a standard sample to test, leading time-consuming and laborious. At the same time the material can't be measured non-destructive testing. In the other hand, silicon-based composite used in the installation is not the shape of a standard sample and can't be modified. So using standard sample test can't represent the use of the actual situation. Electrostatic charge is leaked though surface resistance as well as volume resistivity. Thus, using a three-electrode system which can't support elevated temperature is improper and a new test method is required.

For this reason, an elevated temperature two-electrode resistance properties test system is developed which is proposed in Fig.1. This test system uses two parallel electrodes, greatly reduces the contact area, and ensures the full contact and stability of the contact partner. The electrode length is L. The distance between the two electrodes is d. The general requirement is L=(3~7)d. As measured by a high resistance meter, the resistivity of the sample is as follows:

$$\rho_s = R_s L / d$$

This test system is in line with the EOS/ESD-S11.11-1993 standard. This method can not only measure the resistance of homogeneous material, but also is suitable for multi-layer composite material measurement. The unit of the test result is Ω/□. To ensure the accuracy of the test, when the measured resistivity value is greater than 10^6Ω/□, the measured voltage is 100V. When the resistivity value is less than 10^6Ω/□, the measured voltage is 10V.

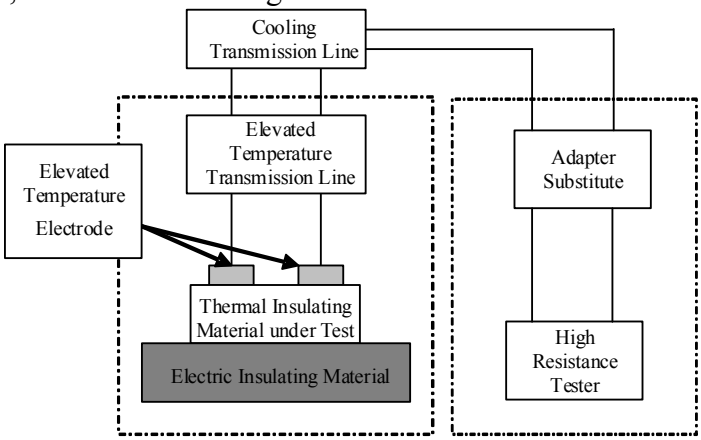

Fig.1 Elevated temperature two-electrode resistivity properties test system

Silicon-based composite materials resistance testing at room temperature

The original silicon-based composite sample and the sample after reentry environment of high temperature ablation are placed in special chamber to assimilate with the environmental temperature and humidity for 48 hours. The internal environment of the chamber maintains 23±2℃,, relative humidity (12±3)%. The test results are shown in Table 1.

As shown in Table 1, the resistivity of original silicon-based composite sample has little difference at different positions, the resistivity are all greater than 10^{10}Ω/□, and the results of several tests appear greater than 10^{12}Ω/□. It indicates that original silicon-based composite material has a very high resistivity at room temperature, it doesn't have electrostatic discharge capability, and anti-static performance is poor. The resistivity of silicon-based composite sample after reentry environment is less than 10^8Ω/□, and most of them are between (10^3~10^4)Ω/□ and even less than 1kΩ/□ at some test direction. It indicates that silicon-based composite sample after reentry environment has a good anti-static properties. But resistivity of the un-burned face of the silicon-based composite sample after reentry environment is very greater than the burned face. The resistivity of the un-burned face is greater than 10^{11}Ω/□, which suggests that this face isn't affected by the reentry environment's elevated temperature. That is because that although the silicon composites changed a lot after

atmospheric ablation, the great thermal insulating capacity help the material to be affected by high temperature and remain a huge resistivity which is almost the same as the original silicon-based composite material.

Table.1 Silicon-based composite materials resistance testing at room temperature

Materials under test	Face under test	Resistivity（Ω/□）
Original composite sample	Frontage	5.25×10^{10} 1.99×10^{10} 3.58×10^{10} 6.33×10^{10} 1.12×10^{11} $>10^{12}$ 4.27×10^{11} $>10^{12}$ 2.30×10^{10} $>10^{12}$ 7.93×10^{10} 4.46×10^{11} 8.30×10^{11} 5.36×10^{11} 7.78×10^{11} $>10^{12}$
	Reverse side	8.66×10^{11} 9.86×10^{10} $>10^{12}$ 6.99×10^{11} $>10^{12}$ $>10^{12}$ 7.06×10^{11} 9.67×10^{10} 1.85×10^{12} 1.96×10^{12} 7.23×10^{11} $>10^{12}$ 1.17×10^{12} 1.95×10^{12} 8.23×10^{11} 1.77×10^{12}
Sample after reentry	Burned Face	2.21×10^{3} 1.61×10^{3} 1.78×10^{3} 2.56×10^{3} 5.35×10^{4} 6.21×10^{4} 5.20×10^{4} 4.32×10^{4} <1k <1k <1k <1k 3.07×10^{8} 4.25×10^{8} 6.23×10^{8} 2.56×10^{7}
	Un-Burned Face	2.68×10^{11} 3.61×10^{11} 3.72×10^{11} 4.96×10^{11} $>10^{12}$ $>10^{12}$ $>10^{12}$ 1.11×10^{12} 1.92×10^{12} 1.02×10^{12} 9.09×10^{11} 8.96×10^{11} 2.22×10^{11} 4.52×10^{11} 8.16×10^{11} 6.77×10^{11}

Silicon-based composite materials resistance testing at elevated temperature

As shown in Fig.1, the platform consists of high-temperature heating systems, cooling systems and the conduction resistance testing system. We use the high temperature furnace in the range of 50 ~ 1000 ℃. Resistance tester is US-made ACL800 resistance tester in the range of $(10^3\sim10^{12})\Omega/\square$. Silicon-based composite material is heated to 300 ℃, 600 ℃ and 700 ℃ individually. The resistance variation with temperature in the cooling process in air naturally is shown in Fig.2, Fig.3 and Fig.4

As shown in Fig.2, Fig.3 and Fig.4, the resistivity will have irreversible change if heated to 700℃ instead of 300℃ and 400℃. The resistivity will decrease will the increase of temperature. From the test results above, it can be found that the resistivity of silicon-based composite materials increases with decreasing temperature. If the thermal load temperature reaches a certain level, the material resistance irreversible changes will take place. In this case, the resistivity will be less than 1kΩ/□ at any temperature. The material which doesn't have irreversible changes, the resistivity changes with temperature can be described with a theoretical model as follow:

$$R = R_0 e^{-BT}$$

Where $R_0 = 7.58\times10^{18}$, B= 0.0142. So, material resistivity increases exponentially with temperature. The higher of the temperature thermal load, the smaller of the parameter R_0 will be.

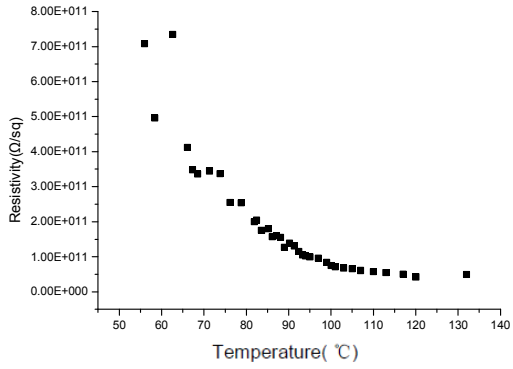

Fig.2 Resistivity changes after heated at 5min 300 ℃

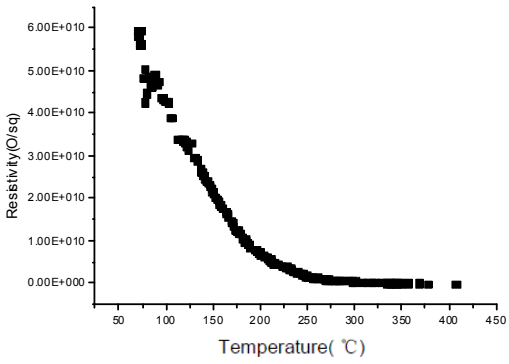

Fig.3 Resistivity changes after heated at 15min 600 ℃

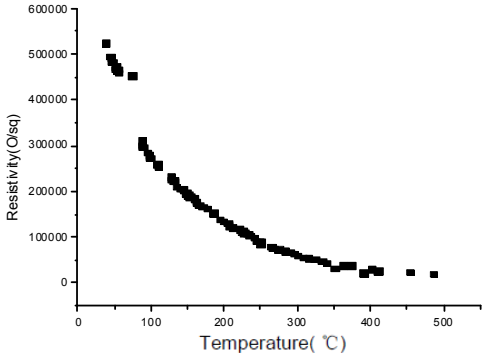

Fig.4 Resistivity changes after heated at 10min 700 ℃

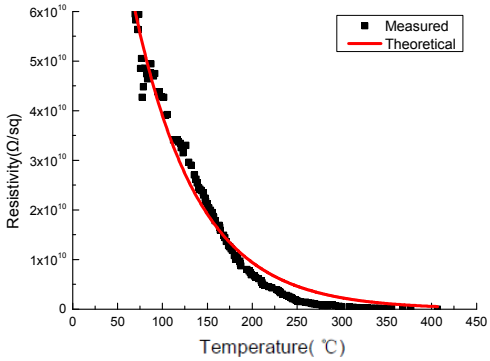

Fig.5 Resistivity changes of measurement and theory

Conclusion

In this paper, elevated temperature two-electrode resistivity properties test system is used to study the resistivity characteristic with temperature. We would come to the conclusion:

(1) The resistivity of silicon-based composite materials at room temperature is maintained at $10^{10}\Omega/\square$ above, and the material has a poor electrostatic discharge capability.

(2) The resistivity of silicon-based composite materials could recover to normal condition if the normal condition is not greater than 600℃.

(3) When the temperature of the heat load is greater than 700℃, the material resistance irreversible changes will take place, and the resistivity can't recover to normal condition

Keywords: Electrical Simulation ； unsteady heat conduction； boundary; innovation experiment

Abstracts: Jilin university innovation experiment Electrical Simulation Experiment and the Analysis of Thermal Conductivity of Materials aims to solve the problem of thermocouple measuring tenderness in error. Thermocouple is used to measure temperature when measuring unsteady heat conduction in laboratory. The improved measuring method of unsteady heat conduction puts the breakthrough on the electric simulation method. The text bench is constructed by different shapes of conductive plate which is made of the graphite conductive paint, and voltmeter is refitted by diodes and controlled transformer. Through the test bench, we finished the simulation of unsteady heat conduction under the similar thermal conductive boundary conditions. Finally, the error analysis of experiment and the advantages of electric simulation method are given in this paper.

0. Introduction

The method of students measuring unsteady heat conduction is based on the single plate gas heating. Heat transfers from the heating surface to the non-heating surface. When the plate reaches the heat through, students will take thermocouples to measure the temperature, then draw the curve of heating temperature and time, and compare the curve to the theoretical curve. However, in non-steady state conditions, thermocouple measurement has errors. Considering the errors, we improve experiment device by using the method of electro-thermal stimulation.

Electro-thermal simulation takes mathematical model. It takes potential distribution to simulate the temperature distribution, electrical resistance to simulate the thermal resistance and electrical current to simulate the thermal current. We ensure the similar geometry and boundary in electrical conduction and the actual heat conductor and determine the temperature distribution of actual heat conductor through measuring the potential distribution of conductor, and then conclude the heat flux intensity.

1. The experiment content

1.1 Experimental apparatus

The experimental device consists of a modified voltage meter, transformer, and different shapes of the self-made modified graphite conductive plates, guide, slick and multi-voltage DC power supply. During the experiment, add the DC power to the ends of the measured material. In order to ensure the safety of circuit, we connect the circuit with a sliding rheostat in series, and then put the refitted voltmeter to one side of the circuit and the probe in parallel. After lapping the circuit, close the switch, and then start the measurement when stable. Adjust the sliding rheostat to the zero potential of the probe, and then make the probe move slowly along the metal guide trail from one side to the other side. Then record the moving distance of X, observe the number of light emitting diodes of converted voltage meter and write down the data (The light emitting diodes use silicon tube and the turn-on voltage is 0.7V). Disposal the data and circulate the potential of each position. Then draw the potential line and determine the isotherm according to the geometric proportion. The experimental device improves the circuit part. We use probe measure the changes of voltage in different positions, and take light emitting diode to display the size of voltage. Based on the

simulation of the temperature field experiment, we study the changes of voltage in different positions of different material by changing the sheet material and shape. Then infer the curve of temperature variation with time in one dimensional unsteady heat conduction and compare the curve with the theoretical curve, and then get the most suitable material.

1.2 Experimental procedures

1. Turn on the power supply. Adjust the range of DC power supply and make the power output 15V DC voltage.
2. When the output voltage of DC power is stable, put the probe on different locations to measure different voltages on different position.
3. Record the number of light emitting diode and each value when the probe is on different position of material.
4. Statistic the data and draw the diagram.

2. Experimental Innovations

2.1 Use electric simulation method

The device gets a temperature distribution of heat conduction indirectly by measuring the electric quantity. Using simple designed test bench can complete the measurement of different materials, and the circuit board which displays the electrical quantity can make the change more intuitive.

2.2 Modified voltage meter, graphite conductive paint and wood made of graphite conductive plate

Conversion voltage meter is composed of a plurality of light emitting diode. Because of the difference of the number of each row of the diode, the voltage of each row of light-emitting diodes are also different, so as to achieve the purpose of reacting the difference of pressure. We use graphite conductive paint and wood to make the graphite conductive plate.Our graphite electrically conductive spray paint on plastic sheeting and get 1.5KΩ per square centimeter of conductive graphite plates, and the test requirement was roughly in line with, and wood cutting, where you can change the shape of the material, you can achieve the purpose of measuring different shaped plate potential.

2.3 Aluminum Strip Posted on graphite electrically conductive plates on each side

In order to make the thermal conductive boundary condition the same, we need to make conductive plates on both sides form equipotential surface, so as to achieve the purpose of modeling two isothermal heat transfer plate surface. Our team decided to affix two aluminum sheets on both sides of graphite conductive plates, and due to the electrical resistance of aluminum graphite is much less than the electrical resistance of graphite conductive paint, this method reaches the purpose of equipotential surface of conductive plate on both sides.

3. Analysis and comparison of experimental results of thermal conductivity

3.1 Electrical simulation method of experimental data and results

Put the plate on a rectangular coordinate system, and the low voltage on the ordinate is the “1 ‘’side, the high voltage on the ordinate is the “6 ‘’ side.

Table1 Below is to measure the material responds to different locations

Abscissa / Voltage /V / Ordinate	1	2	3	4	5
1	9.71	9.70	9.72	9.78	9.86
2	12.41	12.45	12.24	12.31	12.40
3	14.35	14.28	14.31	14.50	14.18
4	16.18	16.19	16.34	16.44	16.28
5	18.21	18.33	18.09	18.12	18.16
6	20.20	20.10	20.08	20.66	20.84

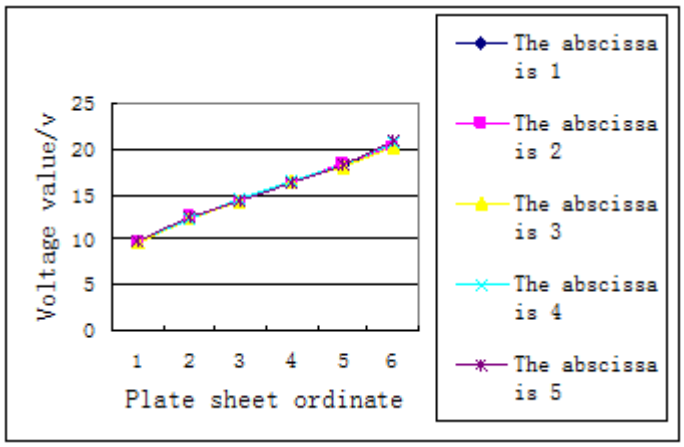

Fig.1 Plate voltage distribution curve

3.2 Direct measurement of thermal conductivity of experimental data and results

Table 2 Thermal conductivity of experimental data and results

Voltage/V	Temperature/$^{\circ}C$				
10	17.9	22.2	23.3	26.1	30.4
15	19.7	24.4	25.6	28.7	34.8
20	21.0	25.8	27.2	30.8	38.1
25	22.9	27.7	29.3	33.2	42.3
30	21.5	27.8	29.6	33.7	43.1

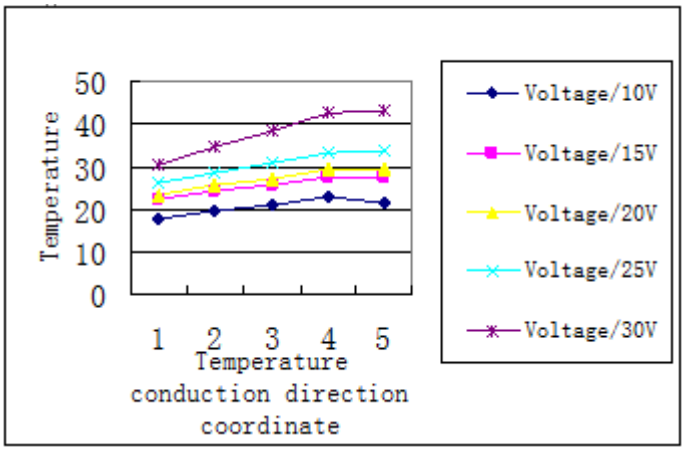

Fig.2 Plate sheet temperature

3.3 **Experimental comparison**

It's not difficult to find direct measurement and simulation of plate temperature distribution simulation of temperature distribution in roughly the same when using the electrical simulation method to analog the distribution of electric potential of materials, and changes of uniform. And electrical simulation method line trend is obvious, and the precision is higher.

4 Error analyses

4.1 Plate ends cannot guarantee form two equipotential surface

This experiment puts two pieces of aluminum sheet on both sides, resistance aluminum strip is much less than the graphite conductive plate, so that the voltage across the board evenly. But because the aluminum strip can not fully contact with graphite conductive plate, there is a certain amount of the contact resistance.

4.2 Other errors

Other errors include uneven distribution of electrical resistance of conductive graphite plates, laboratory temperature influence on electrical resistance of conductive graphite plates, artificial measurement readings.

5. Conclusions

Innovation is the key to national unremitting self-improvement. Students will obtain the ability of innovation in practice after learning and thinking in the class. In this experiment, we combined the electrical knowledge and heat transfer theory, and put it in the experiment. During the process of test bench building and measuring, we also met many problems, but through positive thinking and discussing in team, we got through them. The innovative experimental experience plays a significant role in our life.

Keywords: aerobic granular sludge, SBR, municipal sewage, denitrification and phosphorous removal, DO, organic matter.

Abstract. The experiment uses municipal sewage as the research object and runs SBR reactor in completely aerobic conditions. Through controlling different of DO concentration and COD concentration, we study spreading comparison. The results show that when DO concentration was 1mg/L, the removal effect of aerobic granular sludge process in SBR treating municipal sewage was best, the average removal rate of COD, ammonia nitrogen, total nitrogen and phosphorous was 90.12%,98.95%,87.65% and 83.74% respectively. When COD concentration of influent was about 400mg/L, the treatment effects of aerobic granular sludge for COD, ammonia nitrogen, total nitrogen and phosphorous were all better, the average removal rate was up to 92.33%,98.83%,88.17% and 80.25% respectively.

INTRODUCTION

Aerobic granular sludge process has been proposed as a promising approach to control water contamination in recent years [1, 2].Due to the its own characteristic of structure,simultaneous removal of nitrogen and phosphorous was achieved successfully in a one-reactor system,the system had the distinctive advantages of high activity of microorganisms,good performance of solid-liquid separation,high resistance to organic impact load and long biological chain.Because of all the advantages of AGS system,it had broad development prospect [3].In this study,we compared the influence of dissolved oxygen and organic compound on the municipal wastewater removal performance of aerobic granular sludge process by dynamic tests.The aim of the study was to provide technical support and theoretical basis for the stable operation of aerobic granular sludge process and practical engineering application.

Materials and Methods

The municipal wastewater was used for the experiments. CH_3COONa,NH_4Cl,KH_2PO_4,$NaHCO_3$,$MgSO_4$,$CaCl_2$ and tap water was added into the municipal wastewater in order to achieve the water quality for the test(Table 1).The nutrient solution (Table 2)was combined with the synthetic wastewater with the ratio of 1mL/L.The AGS system was seeded with activated sludge which is mainly flocculent sludge from the secondary sedimentation tank of A^2/O process of the north wastewater treatment plant,Shenyang,China.

Table 1 Water quality for the test

COD/($mg \cdot L^{-1}$)	NH_4^+-N/($mg \cdot L^{-1}$)	PO_4^{3-}-P/($mg \cdot L^{-1}$)	pH
350~400	25~30	6~10	7.0~8.0

Table 2 Composition and concentration of nutrient solution

Contents	Concentration/(mg·L^{-1})	Contents	Concentration/(mg·L^{-1})
$FeCl3·6H_2O$	1300	$CuSO4·5H_2O$	300
$ZnSO4·7H_2O$	120	$CoCl2·6H_2O$	150
$MnCl2·2H_2O$	120	KI	180

A sequencing batch reactor (SBR) with working volume of 7L was used in this study.The temperature of the reactor was controlled by water bath heating system in constant temperature(28℃).The reactor was operated in cycles of five phases,including fill instant(5min),aerobic phases(6h),sludge settling(5min),effluent discharge(5min) and idle phases(345min).In this study,all the indexes were determined according to the standard methods described in w*ater and waste water monitoring and analysis method*（*forth edition*）which was drafted by State Environmental Protection Agency.

Results and Methods

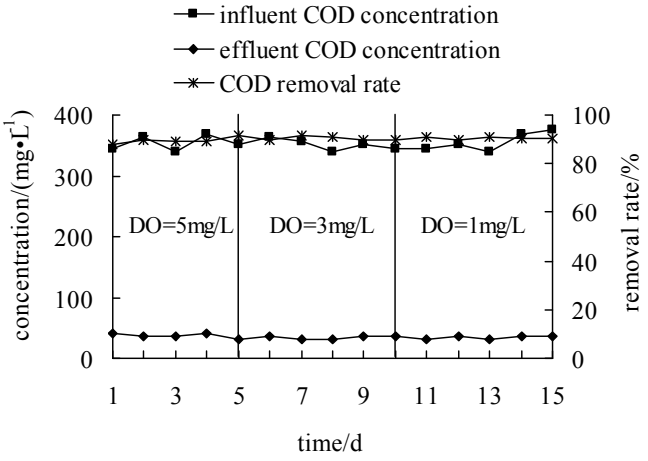

Fig. 1. Removal effect of COD

As shown in Fig.1,when DO was 5mg/L,3mg/L and 1mg/L,the decreased specific DO concentration did not lead to obvious change on the removal efficiency of COD by aerobic granular sludge,the average removal rate of COD was 90.12%.Therefore,when DO concentration was under 1mg/L,it had little effect on the removal efficiency of COD,aerobic granular sludge had good degradation effect of COD.

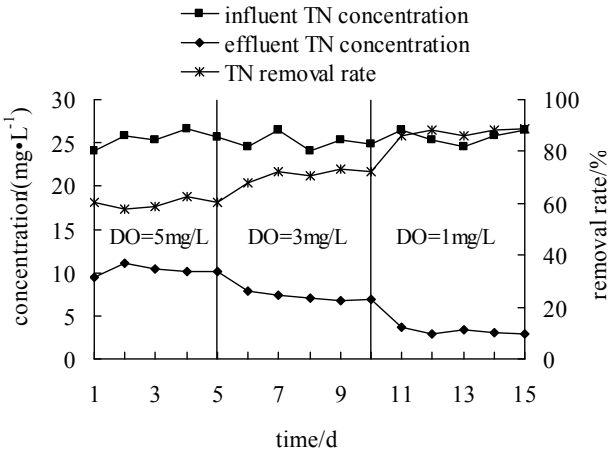

Fig. 2. Removal effect of total nitrogen

As shown in Fig.2,the degradation effect of total nitrogen increased as DO concentration decreased in the reactor,the average removal efficiency of total nitrogen was very low as 59.96%.When DO concentration was 3mg/L,the effluent total nitrogen concentration was still around 7mg/L,it not

achieve a good removal effect.When DO concentration was 1mg/L,the effluent total nitrogen concentration decreased to 3.5mg/L,the average removal rate of total nitrogen increased to 87.65%.

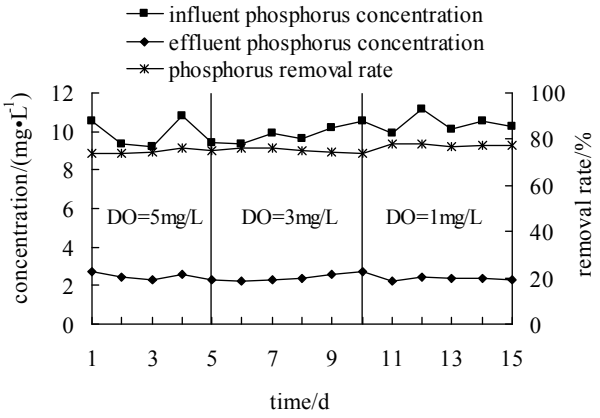

Fig. 3. Removal effect of phosphorus

As shown in Fig.3,when time of aeration is enough,DO concentration had little influence on the effluent PO_4^{3-}-P concentration.The effluent PO_4^{3-}-P concentration was maintained at about 3mg/L.

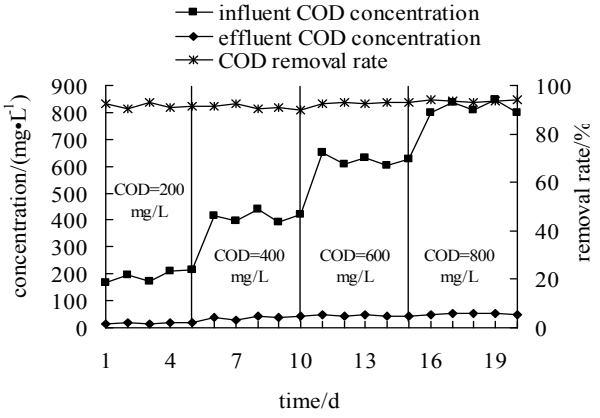

Fig. 4. Removal effect of COD

As shown in Fig.4,aerobic granular sludge could achieve good degradation effect as the influent COD concentration increased.The effluent COD concentration was maintained under 50mg/L,achieved the A in first grade discharge standard.It suggested that aerobic granular sludge had strong shock resistance to influent COD loading rate.

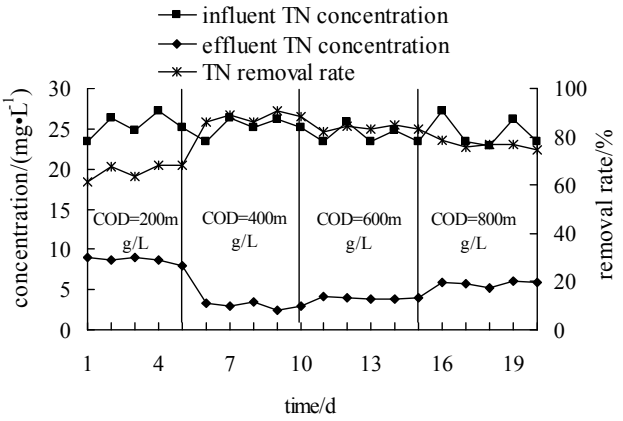

Fig. 5. Removal effect of total nitrogen

As shown in Fig.5,when COD concentration was 200mg/L,the average removal efficiency of TN was only 65.75%.When COD concentration increased up to 400mg/L,the efficiency of denitrification increased steadily and the removal efficiency of total nitrogen increased

considerably.With the further increase of COD concentration,the removal efficiency of total nitrogen started to decrease gradually.

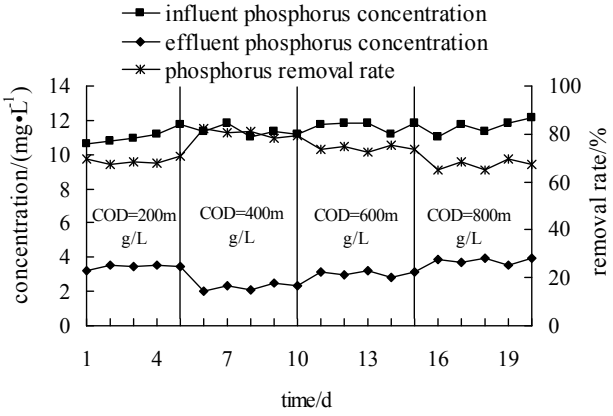

Fig. 6. Removal effect of phosphorus

As shown in Fig.6,when the influent COD concentration was 200mg/L,the average removal efficiency of phosphorous was very low as 68.72%.When COD concentration was 400mg/L,the organic carbon resources in the reactor was sufficient,the activity of microorganisms increased gradually and the average removal efficiency of phosphorous increased 11.53%.With the further increase of COD concentration,the removal efficiency of phosphorous started to decrease.

Conclusions

(1) When DO concentration was controlled at 1mg/L in the SBR reactor,aerobic granular sludge process had the best removal efficiency of nitrogen and phosphorous.

(2) When the influent COD concentration of the SBR reactor was controlled at 400mg/L,aerobic granular sludge system had optimal removal efficiency on COD,total nitrogen and phosphorous.

Flame retardancy finishing on wool fabric via sol-gel method

Zhang Wei, Zhang Qiang-hua, Chen Guo-qiang, Xing Tie-ling*

National Engineering Laboratory for Modern Silk, College of Textile and Engineering,

Soochow University, Suzhou, China

Email: xingtieling@suda.edu.cn

Keywords: flame retardancy; wool; sol-gel; silica/phosphorus

Abstract. In this paper, silica sols were prepared through sol-gel method and applied onto wool fabric flame resistant finishing. In order to gain good flame retardance of wool fabric, the parameters of preparing pure silica sol and the concentration of doped phosphorus (ammonium biphosphate) in silica sol were optimized taking the LOI values of the treated wool as evaluation index.

Introduction

Sol-gel method, a chemical synthesis method initially used for the preparation of inorganic materials such as glasses and ceramics, was generally based on two steps: hydrolysis of metal alkoxides to produce hydroxyl groups, followed by polycondensation of the hydroxyl groups and residual alkoxyl groups to form a three-dimensional network [1]. With a high degree of homogeneity at molecular level, the sol-gel reaction was proved to be an effective way to provide unique capability and novel materials in many fields [2]. As to textiles, sol-gel approach had been successfully applied to functional finishing such as water-repellency [3], antibacterial finish [4] and so on. However，there are little reports on the flame retartancy finishing on wool fabric through sol-gel method. Indeed, flame retartancy finishing on wool, which was one of the most important raw materials in textile industry, was necessary to improve the safety performance as fires occurred frequently. In this work, process parameters of preparation of sols were fully discussed taking the LOI value of the treated wool as index.

Experimental

Material. Wool fabrics (GB/T7568.1-2002) were purchased from Shanghai Textile Industry Institute of Technical Supervision. Tetraethoxysilane(TEOS) was purchased from Sinopharm Chemical Reagent Co.,Ltd. Ethanol(EtOH), hydrochloric acid(HCl) and ammonium biphosphate were purchased from China Sun Specialty Products Co.,Ltd.

Preparation of flame retandancy sols. The silica sol was prepared using tetraethoxysilane as precursor, ethanol as cosolvent, and hydrochloric acid as catalyst. More specifically, tetraethoxysilane was mixed with some ethanol, and then dropped distilled water for pure silica sol or ammonium biphosphate solution for phosphorus doped silica sol while stirring continuously at room temperature. The pH value of both pure and phosphorus doped silica sols were adjusted by hydrochloric acid. Then the whole system was kept stirring at a suitable temperature.

Application of the flame retandancy sols to wool fabric. The wool fabric was treated with the prepared sols at the reacting temperature for an hour on constant temperature vibrator, and then the wool fabric was cured at 160℃ for 6 min, and finally the wool fabric was dried in the air.

Measurements. The limiting oxygen index (LOI) was measured by LCK-09 automatic oxygen index tester according to GB/T 5454-1997.

Results and Discussion

Effect of dosage of water on LOI value of wool treated with pure silica sol preparation

As shown in Figure 1, water dosage affected LOI value of treated wool fabric complicatedly. When the mole ratio of water and tetraethoxysilane (n[H_2O]:n[TEOS]) was lower than 4:1, the LOI value

of the fabric decreased first and then increased with the increase of water dosage. On the other hand, the LOI value of the fabric decreased continuously when the ratio was greater than 4:1. This was because that the hydrolysis was not complete when the mole ratio was smaller than 4 according to Equation 1. The silica particles kept growing until the water dosage was enough to complete the reaction. That was to say, at the very beginning, the silica particles were fairly small that they could penetrate into the fabric well and then adhere to it tightly because of the small size effect, achieving 26.6% of LOI value when n[H_2O]:n[TEOS]=1:1. With the water dosage increasing, on one hand, the size of silica particles became bigger which weaken the small size effect; on the other hand, the number of the silica particles became more which enhanced the effective component of the flame retardant. However, when n[H_2O]:n[TEOS]>4, the hydrolysis reaction was complete and the number of silica particles did not increase with the water increasing. This dilution of the flame retardant system led to the decrease of the LOI of the treated wool fabric. What was more, it was remarkable that small dosage of water could cause the instability of doped silica sols especially when the additive had poor solubility. From the above, n[H_2O]:n[TEOS]=1:1 was chosen to prepare pure silica sol while n[H_2O]:n[TEOS]=20:1 to prepare phosphorus doped silica sols.

$$\text{Hydrolysis : } Si(OEt)_4+4H_2O \leftrightharpoons Si(OH)_4+4EtOH \quad (1)$$

$$\text{-Si-OH+EtO-Si-} \rightarrow \text{-Si-O-Si-+EtOH} \quad (3)$$

Effect of dosage of HCl on LOI value of wool treated with pure silica sol preparation

The reactivity of silicon alkoxide was low so that catalyst either acid or base was needed. Therefore, the structure and the morphology of the resulting network strongly depended on the use of catalyst. As to silica alkoxides, acidic environment accelerated the hydrolysis resulting in the formation of high-density and low fractal dimension structures; while base catalyst promoted the condensation leading to dense and colloidal particulate structures [1]. In this paper, acid catalyst was chosen to prepare silica sols because this kind of sols performed well when applied on fabrics. Figure 2 shows the effect of the HCl dosage on LOI value of the treated fabric. It could be seen from Figure 2 that the LOI value increased from 25.4% to 26.6% with the increase of n[HCl]:n[TEOS] from 0.048 to 0.108. However, the pH of the system dropped much below 1 when the ratio reached 0.108 causing a great loss of mechanical strength of the treated fabric. In conclusion, n[HCl]:n[TEOS]=0.096 was chosen to prepare silica sol which applied in wool fabric treatment.

Effect of dosage of EtOH on LOI value of wool treated with pure silica sol preparation

Ethanol, acting as cosolvent in the preparation of silica sols, was also one of the products of condensation according to Equation 3. It could promote the reaction on molecular level at a small amount but could be an inhibiter or a diluent when the dosage reached the limit. This was proved by Figure 3, LOI value increased gradually with the dosage of EtOH increasing to n[EtOH]:n[TEOS]=3 and then decreased rapidly. As a result, the suggested ratio of EtOH and TEOS was 3 when the LOI value was the highest as 26.7%.

Effect of reaction temperature and reaction time on LOI value of wool treated with pure silica sol preparation

The effects of reaction temperature and reaction time on LOI value of the treated wool were showed in Figure 4 and Figure 5, respectively. It can be seen that with the temperature or time increasing, the LOI value of the treated wool trended to increase as well. That was due to the less reactive silica alkoxides whose reaction needed enough energy to complete. For reaction temperature, although the LOI value gained the highest as 28.1% at 80℃, the better choice was 26.7% at 70℃ considering the yellowing and the mechanical strength of treated fabric. As to reaction time, the LOI value didn't change much at the first hour, and the LOI value of the treated fabric tended to increase gradually and reached the highest as 26.7% when the reaction lasted for 3 hours. Thus the optimal reaction condition was chosen as 3 hours at 70 ℃.

Effect of ammonium biphosphate concentration on LOI value of wool treated with phosphorus doped silica sol

Ammonium biphosphate, as a flame retardant additive, was doped into the pure silica sol to improve the flame retardance of the treated wool. Considering the poor solubility of ammonium biphosphate, n[H2O]:n[TEOS]=20:1 was chosen while other parameters were the same with the process in preparing pure silica sol. Figure 6 showed the LOI values of different concentration from 2% to 12% of ammonium biphosphate doped in silica sol. From that a significant improvement of LOI value of the wool treated with phosphorus doped silica sol was observed even at a small concentration (28.7%at 2%) comparing with the wool treated with pure silica sol (26.7%). For the wool treated with phosphorus doped silica sol, the LOI value increased with the increasing of ammonium biphosphate concentration before 8% which was explained by the flame retardance based on phosphorus. But this growth was not linear which was due to the synergistic effect based on silica and phosphorus. After 8% there was a decline on LOI value and then continued to rise. This was because the effect of flame retardant based on phosphorus alone was beyond the synergistic effect based on silica and phosphorus. However the concentration of phosphorus was

limited because the sol was too unstable to apply on fabric when the concentration was beyond 12%. From the above, concentration on 8% of ammonium biphosphate was a better choice for preparing phosphorus doped silica sol.

Summary
